This 14th annual ED-MEDIA conference serves as a multidisciplinary forum for the discussion and exchange of information on the research, development, and applications on all topics related to multimedia, hypermedia and telecommunications/distance education. ED-MEDIA, the premier international conference in the field, spans all disciplines and levels of education and attracts more than 1,000 attendees from over 50 countries. This document contains papers from attendees representing researchers in over 60 countries, with 162 Full Papers, 255 Brief Papers, and 220 Posters. The focus of ED-MEDIA is technology in education with many different approaches to using the available technology for the realization of educational aims. Topics of papers include: evaluations of new teaching designs, techniques and tools; case studies on the use of technology in physical or virtual classrooms; discussion of new technologies and applications; applications of educational technology in a variety of disciplines; theoretical considerations of the motivations and impact of technology; partnerships and cooperative programs; and accessibility issues for the disabled. There are 2 poster sessions (with 225 posters), 10 panels, workshops, and an evening of special interest group (SIG) sessions. (AEF)
Steering Committee
Chair: Erik Duval, Katholieke Univ. Leuven, Belgium
Rachel Heller, George Washington Univ., USA
Gary Marks, AACE, USA
Craig Montgomerie, Univ. of Alberta, Canada
Ron Oliver, Edith Cowan Univ., Australia
Ivan Tomek, Acadia Univ., Canada

Program Committee
Program Co-Chair: Philip Barker, Univ. of Teesside, UK
Program Co-Chair: Samuel Rebelsky, Grinnell College, USA
Tutorial/Workshop Chair: Catherine McLoughlin, Australian Catholic Univ., Australia
Panels Chair: Karen Swan, Univ. at Albany, USA

Alan Amory, Univ. of Natal, South Africa
Philip Barker, Univ. of Teesside, UK

Alison Young, UNITEC, New Zealand
Preface

Welcome to Denver, Colorado, USA and to ED-MEDIA 2002. We hope you will discover many exciting ideas, be challenged, meet new people, and find yourself energized by the conference!

This year marks the fourteenth appearance of the ED-MEDIA conference, making ED-MEDIA one of the oldest and well-established conferences in the area of educational technology. In celebration of our longevity, we have complimented our strong paper program with some particularly notable keynotes and invited speakers. We are particularly proud of this year’s keynote speakers, each of whom has made strong contributions to the founding of educational computing as a field of study. Alan Kay, one of the leading visionaries in personal computing, has also taken an early leadership role in thinking about ways to use computers to teach children (and about ways to teach children about computers). Andy Van Dam built one of the first hypertext systems (in the late 1960s, for those who think hypertext started with the World Wide Web) and is a leader in computer graphics. Anne Wright has been a leader in educational technology in the UK and beyond and recently served as Chief Executive of Ufi Ltd (which provided an online “University for Industry”). She is currently an E-Learning Strategic Adviser to the Department for Education and Skills in the UK. Finally, Hermann Maurer helped found the ED-MEDIA series of conferences and developed two leading hypertext systems. Dr. Maurer will reflect on the history of multimedia in education.

ED-MEDIA prides itself on being an international conference, and you can see many countries and perspectives reflected in our 162 Full Papers, 255 Brief Papers, and 220 posters. This year, we have papers and posters from researchers in over 60 countries. This program was assembled by the members of our valued international Program Committee, who carefully and rigorously reviewed the many submissions received. The Full Papers received particular attention, with each being reviewed by at least two Program Committee members and only the most meritorious being accepted to the conference. The Program Committee members are asked to consider a number of aspects of each paper, particularly the quality of the work and the expected benefits to the educational community. After the review process, the Chairs and Steering Committee assembled to make final decisions. This year, we accepted slightly less than half of the Full Papers submitted to the conference.

Behind the scenes, much was different in the review process. We have installed a new online reviewing system that makes it easier for Program Committee members to make and add comments on papers and for the Steering Committee to review the work of the Program Committee. We hope that those of you who submitted papers found the online submission system also worked more smoothly. The wonderful folks at AACE are continually working to make the system better and we expect many more improvements in the years to come. In the near future, ED-MEDIA attendees can expect to see an online “plan your conference” system and access to a new AACE Digital Library. If you’d like to learn more about the reviewing process or are interested in joining the Program Committee, please attend the special session on “Reviewing for ED-MEDIA.”

This year, as in recent years, we identified a set of papers as “outstanding”. We began with the Full and Brief Papers that received a score of 5 (on a 5 point scale) from the reviewers and the Full and Brief student papers that received a score of 4.5 or above from the reviewers. The Program Chairs re-reviewed those papers and accepted as outstanding only those that clearly stood out from the rest. Papers were judged on a number of important criteria such as originality/novelty, writing style, technical content, future impact, evaluation, and so on. We
found that the outstanding papers reflected the topical diversity of ED-MEDIA. In the designated outstanding papers, you will find careful studies of the effects of certain technological interventions, case studies that provide more narrative descriptions of the use of technology in teaching (and which we often found to be "real page turners" to use an American colloquialism), descriptions of new projects in educational technology, and even instruments to use in future studies.

As you scan through the papers, you will find many different kinds of paper tied together by some common threads. While the focus of ED-MEDIA is technology in education, there are many different approaches to using the available technology for the realisation of educational aims.

These include:
- Preliminary evaluations of new teaching techniques and tools;
- Case studies on the use of technology in physical or virtual classrooms;
- Discussion of new technologies and applications;
- Applications of educational technology in a variety of disciplines; and
- Theoretical considerations of the motivations and impact of technology.

We expect you'll see this variety reflected in the program.

This year, we have added a special strand on accessibility issues for the disabled. As the Web has grown, so has the importance of making Web materials accessible to all kinds of readers. Accessibility encompasses a wide variety of issues, including access to the Internet, support for multiple languages and multiple cultures, and support for users with disabilities. As the premiere international conference in educational multimedia and hypermedia, ED-MEDIA has long been a leader in publishing papers which consider issues raised by different languages and cultures. This year's special strand both broadens and solidifies our emphasis on accessibility. We both hope and expect that it will be continued at future sessions of ED-MEDIA.

The best educational technology projects look to accommodate different learning styles. While it is not possible to accommodate every learning style in a conference, we have tried to provide a variety of different types of session. Hence, in addition to the keynote speakers, invited speakers, and paper presentations, all of which are generally held in a lecture plus question-and-answer format, we have included a number of other venues for learning and talking about educational multimedia, hypermedia, and telecommunications. These other venues include two poster sessions (with 225 posters), which provide more time for careful consideration and discussion with researchers; 10 panels, which present different perspectives on topics and give attendees a chance to discuss issues with panelists; tutorials, which provide small-group learning situations on a variety of topics; workshops, which provide small-group, hands-on learning sessions on a variety of topics; an evening of special interest group (SIG) sessions, in which attendees with similar interests can discuss particular topics; a varied social program, which gives attendees the chance to interact informally; a group dinner program, which gives attendees better chances to meet new people and discuss topics informally; a variety of meet-the-speakers sessions to give you a chance to interact with keynote speakers, invited speakers, and outstanding paper presenters; and a newcomers session to help new attendees plan how to make the best use of the many compelling opportunities at the conference.

As Conference Program Co-chairs, we have been aided considerably by a number of volunteers and helpers who have given tirelessly of their time. In particular, we must thank the Conference Steering Committee of Erik Duval (Chair), Shelly Heller, Gary Marks, Craig Montgomerie, and Ron Oliver, who led and coordinated the conference this year. We would like to thank the Chairs...
of the various Program Sub-Committees: Karen Swan, Panels Chair; and Catherine McLoughlin, Tutorials/Workshops Chair. We would also like to thank the 85 members of the international Program Committee who provided timely and insightful reviews without complaint and little credit. Finally, we would like to thank Gary Marks and the staff at the Association for the Advancement of Computing in Education (AACE), who organize and sponsor this conference, for their support in this massive endeavor. These folks work incredibly hard behind the scenes to manage all the aspects of the conference. They deal with many complicated situations and handle a variety of requests from the Steering Committee and others.

We look forward to meeting with you during the conference. Remember to spend time talking to colleagues from previous ED-MEDIA conferences and make new friends. As long-time attendees will tell you, what you learn during informal conversations can have as much or even greater impact than what you learn during more formal parts of the program. Think about new collaborations, new projects, and new uses of the work you hear about at this conference. We hope that you will develop new work that you can present next year at ED-MEDIA 2003 in Honolulu, Hawaii, June 23-28, 2003 or at the following year’s ED-MEDIA, which is still in its planning stages. However, we do know that it will be held at a European venue.

Program Chairs:

# Table of Contents

What Have we Learnt in 15 Years About Educational Multimedia? ............................................. 2
Hermann Maurer, IICM, Graz University of Technology, Austria

Macromedia-Washington State Digital Design Curriculum Partnership ........................................... 10
Kirsti Aho, Macromedia, USA

Qualitative Analysis of Information Communication Technology Use on Teaching-Learning Process ....................................................... 11
Kanji Akahori, Tokyo Institute of Technology, Japan

Issues and Prospects of E-Learning in Oman ................................................................. 17
Ali Al Musawi, Sultan Qaboos University, Oman

NDU Knowledge Net: A Web-Enabled Just-In-Time Information Service for Continuing Education .......................................................... 19
Jay Alden, National Defense University - IRM College, USA

Integrating Handheld Technology and Web-based Science Activities ........................................... 25
Turadg Aleahmad, Jim Slotta, University of California, Berkeley, USA

Musical Improvisation: A Model for Infusing New Technologies Into the Design of Instruction ...... 31
Douglas Allen, Daniels College of Business, University of Denver, USA; Dwight Allen, Old Dominion University, USA; Gwendolyn Watson, Cellist, USA; Carl Hoagland, College of Education, University of Missouri, St Louis, USA

WQ: An Environment for Teaching Information Access Skills ......................................................... 34
G. Craig Murray, Robert Allen, Hedong Yang, CLIS, U. Maryland, USA

How are Learning Objects Used in Learning Processes? Instructional Roles of Learning Objects in LOM ........................................................................ 40
Wolfgang Nejdl, Learning Lab Lower Saxony, Germany; Hadhami Dhraief, University of Hanover, Germany; Heidrun Allert, Learning Lab Lower Saxony, Germany

Dual Coding Theory and Computer Education: Some Media Experiments to Examine the Effects of Different Media on Learning .................................................. 42
James Alty, Loughborough University, UK

An investigation of collaborative problem solving using different communications modes in Distance Education ............................................................... 48
Terry Anderson, Athabasca University, Canada; Liam Rourke, University of Alberta, Canada

Digital Disconnect: Students’ Perceptions and Experiences with the Internet and Education ....... 51
Douglas Levin, Jennifer Richardson, Sousan Arafah, American Institutes for Research, USA

Using Critical Components of Communicative to Measure the Distance Learning Experience ..... 53
Gary Archambault, Dakota State University, USA

Policies for Content Filtering in Educational Networks: The case of Greece ................................ 57
Maria Avgoulea, Computer Technology Institute, Greece

Technology Lesson Plans Based on the Sunshine State Standards and the ISTE Standards .......... 63
Judy Bachay, St. Thomas University/Golden Glades Elementary, USA; Aldo Bacallao, Lloyd Estates Elementary, USA; Candace Lacey, Barry University, USA; Mary Kay Bacallao, St. Thomas University/Wellesley Elementary, USA; John Enger, Barry University, USA

Adaptive Hypermedia Educational System based on XML Technologies ........................................ 65
Yeong Tae Baek, Kimpo College, Korea (South); Changjong Wang, Inha University, Korea (South); Sehoon Lee, New Jersey Institute of Technology, USA

Collaborative teachback with a statistical cognitive tool: A formative evaluation ...................... 71
Ken Mavor, University of Southern Queensland, Toowoomba, Australia; John Bain, Griffith University, Brisbane, Australia

The Catalyst Initiative: Integrating Support and Development through Collaboration ................ 77
Tom Lewis, Laura Baldwin, University of Washington, Educational Technology Development Group, USA

Models and Methodologies for Multimedia Courseware Production ........................................ 79
Philip Barker, University of Teesside, UK

Skill Sets for Online Teaching ........................................................................................................... 85
Philip Barker, University of Teesside, UK

Distributed Internet2-Based Mission Training and Collaborative Research: Connecting and Integrating Multiple Simulation Platforms ......................................................... 91
Stuart Aldridge, 21st Century Systems, Inc., USA; Christopher Barnes, Warfighter Training Research Division, USA; Plamen Petrov, Alex Stoyen, 21st Century Systems, Inc., USA; Linda Elliott, Veridian Engineering, USA
A semi-automatic tool for the indexation of learning objects ............................................ 190
Yolaine Bourda, Walid Kekhia, Bich-Liên Doan, Supelec, France

Exploring the development of learning communities in online settings .................................. 192
Chris Brook, Ron Oliver, Edith Cowan University, Australia

Web-based Interactive Visualization in an Information Retrieval Course ............................... 198
Peter Brusilovsky, University of Pittsburgh, USA

Group members’ Cooperative Orientation and Academic Achievement as Determinants of Perceived Quality of Group Functioning ................................................................. 204
Jan Van den Buick, Steven Eeggermont, Herman Buelens, K.U.Leuven, Belgium

Interacting with Interactive Papers: A Situated Evaluation of a Computer-Supported Collaboration Tool .......................................................................................................................... 208
James Buehl, University of Illinois at Urbana-Champaign, USA

A Framework for the Instructional Design of Multi-Structured Educational Applications .......... 210
FELIX BUENDIA-GARCIA, Universidad Politécnica de Valencia, Spain

The Construction Kit Metaphor for a Software Engineering Design of an E-Learning System ...... 216
Michael Bungenstock, University of Hamburg, Dept. of Informatics, IMA Lab, Germany; Andreas Baudry, University of Hamburg, Dept. of Informatics, IMA Lab, Germany; Baerbel Miersching, University of Hamburg, Dept. of Informatics, IMA Lab, Germany

Collaboration by Design: Creating a Course Explicitly for a Collaborative Environment .......... 218
Michael Burke, Innovative Technology Center, University of Tennessee, USA

Assessing the Use of Technology Student Responses .............................................................. 220
Karin Camihort, Springfield College, USA

First Year of Technology Mentoring for Teachers and Faculty: Lessons Learned ..................... 222
Shirley Campbell, Songdil Ogul, University of Pittsburgh, USA

Computer Mediated Collaboration in an Academic Setting. An Experience on Web Business Models at the University of Lugano (Switzerland) ................................................................. 228
Lorenzo Cantoni, Davide Bolchini, Università della Svizzera italiana, Switzerland

A Classification of Document Reuse in Web-based Learning Environments ............................. 234
Kris Cardinaels, Henk Olivié, Erik Duval, K.U.Leuven, Belgium

Issues in Automatic Learning Object Indexation ..................................................................... 239

  February 24, 2003
• Proceedings File Due:
  May 6, 2003
• Early Registration Deadline:
  May 6, 2003

Co-sponsored by:
Journal of Interactive Learning Research (JILR)
Journal of Educational Multimedia and Hypermedia (JEMH)
International Journal on E-Learning (JEL)
www.aace.org/pubs
Hosted by: University of Hawaii
ED-MEDIA 2003 – World Conference on Educational Multimedia, Hypermedia & Telecommunications is an international conference, organized by the Association for the Advancement of Computing in Education (AACE). This annual conference serves as a multidisciplinary forum for the discussion and exchange of information on the research, development, and applications on all topics related to multimedia, hypermedia, and telecommunications/distance education. ED-MEDIA, the premier international conference in the field, spans all disciplines and levels of education and attracts more than 1,500 attendees from over 60 countries.

We invite you to attend ED-MEDIA 2003 and submit proposals for papers, panels, tutorials, workshops, posters/demonstrations, corporate demos, and SIG discussions. Each proposal will be peer-reviewed by three reviewers for inclusion in the conference program, proceedings book, and CD-ROM proceedings.

Information for Presenters
Details of presentation formats are given on the following pages. The general principles applying to all are:

► All communication will be with the contact presenter who is responsible for communicating with co-presenters of that session.

► All presenters must register and pay the registration fee (approximately $395 members, $435 non-members (US$)).

► The conference will attempt to secure basic equipment needed for presenters. However, when special equipment cannot be obtained, presenters may need to bring or rent equipment.

Proceedings
The Proceedings book and CD-ROM are published by AACE. These proceedings serve as major sources in the multimedia/hypermedia/telecommunications community, reflecting the current state of the art in the discipline. In addition, selected papers may be invited for publication in the Journal of Educational Multimedia and Hypermedia (JEMH), International Journal on E-Learning (UEL), or Journal of Interactive Learning Research (JILR).

Hotel & Travel Arrangements
Special hotel room rates will be available to conference attendees. Discount airfares will be available from a designated airline carrier.

Paper Awards
Papers present reports of significant work or integrative reviews in research, development, and applications related to educational multimedia, hypermedia and telecommunications/distance education.

All presented papers will be considered by the Program Committee for Outstanding Paper Awards. There is also an award for Outstanding Student Paper (therefore, please indicate if primary author is a full-time student).

ED-MEDIA 2003 Topics
The scope of the conference includes, but is not limited to, the following major topics as they relate to the educational and developmental aspects of multimedia/hypermedia and telecommunications:

Infrastructure
- Architectures for Educational Technology Systems
- Design of Distance Learning Systems

Distributed Learning Environments
- Methodologies for System Design
- Multimedia/Hypermedia Systems
- WWW-Based Course-Support Systems

Tools & Content-Oriented Applications
- Agents
- Authoring Tools
- Evaluation of Impact
- Interactive Learning Environments
- Groupware Tools
- Multimedia/Hypermedia Applications
- Research Perspectives
- Virtual Reality
- WWW-Based Course Sites
- WWW-Based Learning Resources
- WWW-Based Tools

New Roles of the Instructor & Learner
- Constructivist Perspectives
- Cooperative/Collaborative Learning

Implementation Experiences
- Improving Classroom Teaching
- Instructor Networking
- Instructor Training and Support

Pedagogical Issues
- Teaching/Learning Strategies

Human-Computer Interaction (HCI/CHI)
- Computer-Mediated Communication
- Design Principles
- Usability/User Studies
- User Interface Design

Cases & Projects
- Country-Specific Developments
- Exemplary Projects
- Institution-Specific Cases
- Virtual Universities

About AACE
AACE is a non-profit, international organization whose purpose is to advance the knowledge and quality of learning and teaching at all levels through the encouragement of scholarly inquiry related to information technology and education and the exchange of research results, developments, and applications through publications and conferences for its members.

JOURNALS
- International Journal on E-Learning (UEL)
  (Corporate, Government, Healthcare, & Higher Education)
- Journal of Educational Multimedia and Hypermedia (JEMH)
- Journal of Computers in Mathematics and Science Teaching (JCMT)
- Journal of Interactive Learning Research (JILR)
- Journal of Technology and Teacher Education (JTT)
- Information Technology in Childhood Education Annual (ITCE)

ELECTRONIC JOURNALS
- Educational Technology Review (ETR)
- Contemporary Issues in Technology & Teacher Education (CITE)

Article abstracts for each journal are available at http://www.aace.org/pubs

CONFERENCE
ED-MEDIA – World Conference on Educational Multimedia and Hypermedia & Telecommunications
June 23-28, 2003; Honolulu, Hawaii USA

35 BEST COPY AVAILABLE
Submission Information

FULL PAPERS

Presentation time: 25 minutes
Submission length: 4-6 pages (2,500-3,750 words)
Proceedings length: 6 pages maximum
AV equipment provided: PC, Projector, Internet, VCR

Papers present reports of significant work or integrative reviews in research, development, applications, and societal issues related to all aspects of the conference topics.

Systems & Resources
Papers related to projects, technical developments, systems, and resources.
The paper should include:
• Whether this work is just beginning, on-going, or completed;
• The partners involved;
• The major goals and the basic approach - this includes the educational problem addressed or the new educational opportunity created;
• A clear description of what has been developed, including schematic overviews and screen dumps if applicable;
• Future work and implications for others.

The reference list for this kind of paper should include URLs for the work, and at least a few literature references.

Conceptual & Empirical Studies
Reviews, conceptual overviews, evaluations, and empirical studies.
The paper should include:
• The topic;
• The motivation for the work;
• The major questions addressed;
• The general process and conceptual framework, with references to literature;
• The concrete method, with sufficient detail on instruments and procedures;
• Major points or results; and
• Implications.

This paper category requires a strong and up-to-date well synthesized literature review, with work from a variety of sources (not just the research team of the author), and also an appropriate writing and presentation style for a scholarly review or overview.

Case Studies
Papers related to local experiences (e.g., a course or a prototype tested in a local situation).
The paper should include:
• The most important features of the context;
• A description of the problem in both local and conceptual terms;
• A description of who, what, why, and how, including screen dumps if relevant;
• Implications for the local setting or the local prototype; and
• Implications for others outside the local setting.

This paper category should include a reference list with relevant URLs, and a few citations to papers related to the local problem, but from outside the local setting. The latter is to indicate that the author can see the local situation in a broader and more general context.

Other
For authors who do not feel they fit in any of the above. The Program Committee may request that the author revise the paper to relate to one of the above categories, or may accept it as submitted.

BRIEF PAPERS

Presentation time: 15 minutes
Submission length: 2-3 pages, 1,250-1,875 words
Proceedings length: 2 pages maximum
AV equipment provided: PC, Projector, Internet, VCR

These papers are brief, more condensed presentations or work-in-progress projects.

New Developments
Descriptions of new extensions to existing projects or newly initiated projects.

Project Opportunities
Descriptions of projects underway that include opportunities for additional project partners.

Demonstrations

Other
For authors who do not feel they fit in any of the above. The Program Committee may request that the author revise the paper to relate to one of the above categories, or may accept it as submitted.

The submission should include:
• What is going to be shown or demonstrated or offered;
• The major aspects;
• The context or motivation; and
• Relevant URLs or literature references.

PANELS

Presentation time: 1 hour
Submission length: 2-3 pages, 1,250-1,875 words
Proceedings length: 4 pages maximum
AV equipment provided: PC, Projector, Internet, VCR

A panel offers an opportunity for 3-5 people (including the chair) to present their views or results on a common theme, issue, or question and discuss them with the audience. Panels should cover timely topics related to the conference areas of interest. Panel selection will be based on the importance, originality, focus, and timeliness of the topic; expertise of proposed panelists; as well as the potential for informative (and even controversial) discussion.

Panels must allot at least 50% of the time for interaction and discussion with the audience.

The panel proposals should include:
• Description of the panel topic, including why this topic is important to Conference attendees; and
• Brief position statement and qualifications of each panelist.

ROUNDTABLES

Presentation time: 1 hour
Submission length: 2-3 pages, 1,250-1,875 words
Proceedings length: 150 words (to be published only in Abstract Book)
AV equipment provided: electricity

These sessions allow maximum interaction in informal, small-group discussions on a single topic. The format is appropriate for papers, projects, or works-in-progress that encourage discussion. Roundtables share a room with 2-3 other concurrently held Roundtables.

VIDEO FESTIVAL

Presentation time: 1 hour
Submission length: 2-3 pages, 1,250-1,875 words
Proceedings length: 2 pages
AV equipment provided: VCR, PC, Projector, Internet

The field has matured to the point that we have a growing number of video resources – cases, classroom/training video clips, and many other forms. Presenters should have a short handout on the video and use most of the time showing the video.
INTERACTIVE SESSIONS

Presentation time: 1 hour
Submission length: 2-3 pages, 1,250-1,875 words
Proceedings length: 3 pages
AV equipment provided: PC, Monitor, Internet

If you have mastered a new piece of software (or a new version) that others would be interested in learning about, submit a proposal for an Interactive Session. In this informal session, you will demonstrate the software, illustrate the process of using it, show participants some of the complexities and tricks about it, and give them an opportunity to try it themselves.

These sessions are also appropriate for instructional strategies, procedures, and evaluation procedures. The idea is not to give a definitive workshop on the topic, but to provide participants with enough information to help them decide whether their needs can be met with the program or procedure.

Include a description of the software to be used by participants, the objectives of the session, and the intended audience (experience level and prerequisites). These presentations share a room with 2-3 other concurrently held Interactive Sessions.

TUTORIALS / WORKSHOPS

Presentation time: 3.5 or 7 hours
Submission length: see information below
Proceedings length: no pages
AV equipment provided: PC, Projector, Internet (Tutorial); PC, Projector, PC Lab, Internet (Workshop)

Tutorials and Workshops are intended to enhance the skills and broaden the perspective of their attendees. They should be designed to introduce a rigorous framework for learning a new area or to provide advanced technical training in an area. Submissions will be selected on the basis of the instructors’ qualifications for teaching the proposed Tutorial or Workshop and their contribution to the overall conference program. Workshops differ from Tutorials by involving hands-on experience with hardware/software provided.

Note: Few Workshops are selected because a tab of equipment is required for each. If you submit a Workshop proposal, please indicate if your proposal is also appropriate for presentation as a non-hands on Tutorial.

Tutorial/Workshop proposals should include:
- Clear description of the objectives;
- Intended audience (experience level and prerequisites);
- Proposed length (3.5 hours or 7 hours);
- 200-word abstract;
- 1-page topical outline of the content; and
- Summary of the instructor’s qualifications.

POSTER / DEMONSTRATIONS

Presentation time: 2 hours
Submission length: 2-3 pages, 1,250-1,875 words
Proceedings length: 2 pages
AV equipment provided: 4'x8' poster board, 6' table, 2 chairs, electricity, Internet if wireless card & PC brought

Poster/Demonstration sessions enable researchers and non-commercial developers to demonstrate and discuss their latest results and developments in progress in order to gain feedback and to establish contact with similar projects.

Poster/Demonstration proposals should include:
- Description of the planned Poster/Demonstration; should emphasize the problem, what was done, and why the work is important.

Poster/Demonstration presenters will be required to arrange for their own systems software and hardware.

CORPORATE DEMONSTRATIONS/LITERATURE

Presentation time: 2 hours
Submission length: 1-2 paragraphs
Proceedings length: no pages
AV equipment provided: 4'x8' poster board, 6' table, 2 chairs, electricity, Internet if wireless card & PC brought

Demonstrate and discuss your company’s products, services, developments, applications and research, inform the audience of your future directions, gain feedback, and establish contacts.

Scheduled with Poster/Demonstrations grouped together in open exhibition-style, usually all in one hall. This is an informal event with a circulating conference-wide audience. Sales are permitted. You may stock and sell your product at your table.

CORPORATE SHOWCASES

Presentation time: 30 minutes
Submission length: 1-3 pages (625-1,875 words)
Proceedings length: no pages
AV equipment provided: PC, Projector, Internet, VCR

Demonstrate and discuss your company’s products, services, developments, applications and research, inform the audience of your future directions, gain feedback, and establish contacts.

Scheduled concurrently only with other Showcases. Presentation rooms generally accommodate 50-150 people, theatre-style. This is more of a formal presentation than the Corporate Demonstration.

SIG (SPECIAL INTEREST GROUP) DISCUSSIONS

Presentation time: 1 hour
Submission length: 1-3 pages (625-1,875 words)
Proceedings length: no pages
AV equipment provided: PC, Projector, Internet, VCR

To encourage informal interaction among individuals with common interests, SIG discussion groups will be formed based upon proposals accepted under the Call for Participation. Also, new SIG discussion groups may be formed either formally or on an impromptu basis when at the conference.

SIG Discussion proposals should include:
- Description of the discussion topic emphasizing the problem or issue and why the work is important; and
- Indication of whether you are willing to chair the discussion.

SUBMISSION REQUIREMENTS

Submit all proposals by completing the Web form at: http://www.aace.org/conf/edmedia

All proposals must be submitted by uploading PDF, Word, RTF, or Postscript file using the Web form. No hard copy paper, faxed, or e-mail submissions will be accepted.

Please send your proposal only ONE time.

The exciting island of O’ahu, Hawaii, the home of Honolulu and Waikiki, is the site of ED-MEDIA 2003.

Whether your idea of fun is soaking up the sun on a pristine, white sand beach or nightclubbing in Waikiki, hiking the trails or sampling some of the fantastic Hawaiian Regional Cuisine, we know that you’re going to enjoy yourself on O’ahu.

Over 125 miles of beaches surround two magnificent mountain ranges punctuated with a vibrant city, colorful little communities and highlighted by dozens of the most scenic spots on earth. Far and away the most diverse of the Hawaiian Islands, there’s something here for everyone. No other American city could offer you the opportunity to surf the world’s biggest waves, snorkel a lagoon, hike into a dormant volcano, golf at a dozen championship courses, and catch the sunset from a five-star restaurant. All within an hour’s drive of your hotel room.

The island is a study in contrasts: green forests and glorious beaches; fresh, clean bays, rolling hills, dramatic cliffs and sweeping vistas counterpoised with the life of a vibrant city. From the hustle and bustle of Chinatown to the rolling surf of O’ahu’s spectacular North Shore, get ready for an adventure.

For sheer variety of things to do, the Island of O’ahu is unparalleled. Outdoor activities range from the calm (a cool moonlight walk along Waikiki Beach), to the heart-stopping (hang-gliding off a thousand foot cliff in Waimanalo). All 103 sandy beach sites on O’ahu are open to the public, and nearly 600 of the state’s top surfing spots are here, including Waimea Bay and the Banzai Pipeline, considered among the most challenging surf breaks in the world.

Nowhere does East meet West more obviously or successfully than in the arts (and the cuisine) of O’ahu. Collections built over the last two centuries reflect influences from Europe and Asia. Each wave of immigration brought its own cultural traditions and the result is that O’ahu, like no other place on earth, has become a cultural repository for the artistic traditions of Polynesia, China, Japan, Southeast Asia and the West.

Over fifty ethnic groups are represented on the island of O’ahu, making this one of the most culturally diverse and racially integrated places on the globe. For the million people who live in the State of Hawaii, Honolulu is ‘the big city,’ so we’re fortunate to have more than our share of nightlife and cultural activity. This includes theater, opera, an active symphony program, stage shows and comedy, as well as traditional island entertainment such as the hula.

O’ahu is where the cultures of the Orient have blended with the culinary traditions of Europe to create “Hawaiian Regional Cuisine,” combining the spices from all over the world in a remarkable blending of Eastern presentation and Western substance. You can also sample ethnic dishes ranging from the exotic spices of Southeast Asia, to the drama of an original Hawaiian luau to the more familiar western cuisine of Italy and France.

Association for the Advancement of Computing in Education

Membership Information • Conferences • Publications

Invitation to Join
The Association for the Advancement of Computing in Education (AACE) is an international, non-profit educational organization. The Association's purpose is to advance the knowledge, theory, and quality of teaching and learning at all levels with information technology. This purpose is accomplished through the encouragement of scholarly inquiry related to technology in education and the dissemination of research results and their applications through AACE sponsored publications, conferences, and other opportunities for professional growth.

AACE members have the opportunity to participate in topical and regional divisions/societies/chapters, high quality peer-reviewed publications, and conferences.

Join with fellow professionals from around the world to share knowledge and ideas on research, development, and applications in information technology and education. AACE's membership includes researchers, developers, and practitioners in schools, colleges, and universities; administrators, policy decision-makers, professional trainers, adult educators, and other specialists in education, industry, and government with an interest in advancing knowledge and learning with information technology in education.

Membership Benefit Highlights
- Gain professional recognition by participating in AACE sponsored international conferences
- Enhance your knowledge and professional skills through interaction with colleagues from around the world
- Learn from colleagues' research and studies by receiving AACE's well-respected journals and books
- Receive a subscription to the Professional Member periodical Educational Technology Review [electronic]
- Receive discounts on multiple journal subscriptions, conference registration fees, proceedings books & CD-ROMs

Advancing Knowledge and Learning with Information Technology
KEYNOTE PAPERS
What Have we Learnt in 15 Years About Educational Multimedia?

Hermann MAURER, Graz University of Technology, Graz/Austria
Web: www.iicm.edu/maurer
Email: hmaurer@iicm.edu

Abstract: This talk consists of three parts: First, I start with a brief review of the history of multimedia in education as we have experienced it since the first ED-MEDIA: it was then still called ICCAL and held in Calgary in 1987. I will argue that the progress in handling media has helped, but that the major breakthroughs have been on other fronts, such as the better understanding of different learning models (behaviorism, cognitivism and constructivism or incidental vs. explicit learning). We have a more realistic appreciation of what intelligent tutoring systems can do and cannot do. We have learnt that the administration of students, authors, tutors, courses etc. is much more important than previously thought. We seem to agree that powerful authoring tools are essential, but substantial courseware libraries cannot be built unless systematic re-use of modules based on meta-data and presentation standards is supported. We also have learnt that standardization as a whole is a very central issue.

In the second part of the talk I concentrate on the current state of affairs: After all we now realize that computer networks have opened the way for entirely new approaches involving much more communication, collaboration and team work: some ideas of intelligent tutoring systems have e.g. been successfully replaced by techniques involving networks; I will mention the importance of feedback, active documents and knowledge management in this context. In general, the most dramatic step forward has been the recognition that individual multimedia packages cannot be as effective as they should be in the absence of powerful, networked learning environments. Such environments are starting to be visible on the horizon. I also mention how the role and success of educational multimedia is rather different in schools and universities when compared to industrial applications.

In the third part of the talk I take a peek into the future, by presenting one scenario for mobile computing and the serious implications this has not just for how we will learn in the future, but also for what we will have to learn.

It is well known that the first serious attempt to use computers for educational purposes was the PLATO system developed in the early sixties at the University of Illinois and later commercialized by the then powerful Control Data Corporation. Of its many competitors, PLATO did fairly well for quite a long time. PLATO went through many versions, but the basic idea was to offer a central computer with courseware and use the material from a (then very rudimentary) terminal. However, the fact that all students accessed the same computer allowed for some communication between participants, for keeping track of scores and other statistical information, including feedback on the quality of the courseware. Despite all these features, PLATO never achieved a real breakthrough.

Because of this, alternatives started to be considered. It is typical that at the first of our meetings (Calgary, 1987) topics such as hypertext (allowing for more freedom in the navigation of material), pedagogical and didactic rules for preparing courseware, using the emerging color-graphic features on PC's and using (analog) videodisks that then represented the ultimate multimedia technology were main topics. The networking aspect, one of the main assets of PLATO, was almost forgotten. I happened to be one of the program chairs of that first conference.
and was probably one of the few who had emphasized the need to not forget networking already even before this first meeting in Calgary at the major IFIP conference in Ireland [1].

It is intriguing to see that the topics mentioned, combined with attempts to use elements of artificial intelligence for intelligent tutoring systems (student modeling) and the advent of all kinds of authoring systems including Hypercard on Apple computers kept dominating our conference series for the next three meetings in Dallas 1989, Hagen 1990 and Wolfville 1992. Indeed, no researcher in the field dared not to produce such a system: I was no exception [7]. Mind you, the underlying technology started to change: instead of videodisks, CD ROM's and CD-I's (the latter now almost forgotten) and the examination of strategies for learning gained importance, and networks started to play a more prominent role again, mainly due to the impact Hypermedia systems (such as Intermedia at Brown University); also, the first signs of Internet based systems from Gopher to Hyper-G (now Hyperwave) and WWW started to appear.

By the time ICCAL had changed its name and had become ED-MEDIA (Orlando 1993) Hypermedia based ideas (indicating of what would happen with WWW) and advanced authoring facilities competed with the continuous discussion of learning models. It is now recognized that the behavioristic approach is justified only for "rote learning of facts", and that cognitivistc approaches (requiring real understanding) or constructivistc techniques (where learners have to actually discover, not just to understand situations and solutions) are more desirable. However, the battle between cognitivism and constructivism continued well beyond ED-MEDIA 94 (in Vancouver): we believe that most persons are now happy to accept that both approaches have their role to play, yet some extremists will still claim that one of the two will be ideal for all situations. Also, other ideas that are kind-of orthogonal like explicit vs. implicit learning are still being discussed till today [9]. ED-MEDIA 95 in Graz, Austria, was the first ED-MEDIA where the Internet and WWW started to become central topics... and this has not changed since. The importance of communication and computer supported collaborative work as component of Web-based teaching support systems started to grow increasingly, as is witnessed by a slate of papers in this area presented at ED-MEDIA 96 in Boston. Despite the fact that a new conference series WebNet (now e-Learn with WebNet symposium, this year in Montreal, see www.aace.org/conf/webnet) was split off from ED-MEDIA in 96, ED-MEDIA continued to explode: the 1997 conference that returned to its roots in Calgary was the first one where the printed proceedings consisted of two volumes (to expand to three volumes by 2001!). The fact that the 97 conference had as subtitle ED-TELECOM 97 says it all: educational applications without communicational networks started to look very obsolete. This trend continued in 98 at ED-MEDIA in Freiburg and 99 in Seattle: however, the continuing spread of large educational environments made it more and more important to talk about standardizing formats and using meta-data and meta-data standards. To use electronic educational material on a large scale it is necessary to be able to locate and re-use material created elsewhere. It is with satisfaction that we can observe a continued harmonization between North-American and European efforts in this important area. It is also gratifying to see that the necessity for communication, collaboration and large digital libraries accessible via the Web is now universally accepted as basis for viable learning systems as is clearly documented in the large number of papers in this area both at ED-MEDIA 2000 in Montreal and 2001 in Tampere, Finland. It has also become clear that a substantial learning system needs a huge array of administrative features and that the authoring of material is just a small part of what is necessary to make e-Learning work: this is quite in contrast to the days when e-Learning and authoring of material was almost used synonymously.

2. Current State and Lessons Learnt

Typical for today's situation is the fact that we have ceased to talk about learning applications, are using the term learning-platform less and less, and seem to be moving to the terminology "Learning Environment". Such a learning environment consists of (a network of) servers that offer a variety of components:
Courseware modules (re-usable since they follow one of the accepted standards and are searchable due to meta-data that is attached to the modules and is also hopefully standardized)
- Tools to create, combine and modify such modules into new ones
- Tools that allow the administration of the modules mentioned, of authors, teachers, tutors and students, each with a block of statistical data that is gathered as the system is used
- A set of features for communication and collaboration including e.g. chats and discussion forums
- Facilities that allow to use the system for various learning paradigms, different level of learners, provides a high degree of interactivity and powerful tools for (self) testing and feedback

Above list looks innocently simple and complete. It is certainly neither.

First, throughout the discussion we have been using the term "courseware module" without further explanation, nor have we ever stated what it means to have a "high level of interactivity". In fact, both things are closely related. An interactive courseware module is not a sequence of Web pages that one can click through, and it does not become much more interactive if a movie, even a simulation allowing various parameters, or some fill-in questions are allowed. In a cognitivistic approach (and this is still more true in the case of constructivism) a courseware module will be a sophisticated piece of software, hardly the kind of thing one can create with a WWW editor, or the standard authoring system. A high level of interactivity also implies facilities for customization, personalization and active documents, as will be discussed below!

Second, it would take a lengthy paper on its own to describe tools for handling and modifying courseware modules to the extent desirable; and this is even more true of administrative tools that can range from trivial (and hence useless) to very, very sophisticated. Some more details can be found in [8].

Third, innocent looking words like "discussion forum" are really like the mythical box of Pandora: once you start to seriously use a discussion forum with a sizeable group of users the number of issues arising is mind boggling: from questions of the levels of anonymity, to tools for structuring a discussion, to the issue of meta-data for contributions (!), to the issue of active notification of users, to the fact that any large discussion forum has to provide a substantial number of different views of the contributions, to tools for "positive" and "negative" filtering, just to name a few examples. If more complex collaboration tools are to be involved (and they should be) all issues surrounding computer supported collaborative work (CSCW), now discussed in entirely separate conferences, start to be important.

Fourth, systems that really support all kinds of learning paradigms (from e.g. behavioristic fact learning to constructivistic knowledge discovery) are not available "from the rack" but can at best be customized on the basis of generic platforms. To build Learning Environments catering to various learning styles and levels of knowledge requires sophisticated pre-tests both on a cognitive and a knowledge level: again, both tasks have not even been solved in full generality, so far.

Fifth, systems should at least allow to work with them by adding notes (for oneself or a group). They should allow to insert stuff from other sources (marked as such), including of course links, and must provide access to rich background libraries [2]: it must be possible to incorporate parts of material found in such libraries into the courseware modules for the benefit of an individual or a whole group of persons. They must allow asking questions at any point, with the system answering automatically if similar questions have been asked before (as is done in the "active document concept" [3]) or else they pass on the question to tutors or experts who answer them immediately (if online) or "asynchronously", otherwise. Customization should go beyond the courseware module level: it should allow persons to view the catalogue of material offered from their perspective.

Above points are not supposed to be exhaustive (e.g. the self-testing and evaluation aspect have not even been touched upon), but just serve to show how complex good e-Learning environments are. In this sense we have learnt that e-Learning goes much beyond a sequence of beautiful Web-pages with some question/answer material and a few simulations plus Email for communication thrown in. Rather, much effort is required to build a
credible e-Learning platform. My team and I have worked on a system Hyperwave that is the basis of an advanced e-Learning system for many years [4]: it is available for non-commercial use free of charge for schools and accredited universities. It is the outgrowth of hundreds(!) of person years. It keeps amazing me that such huge efforts keep being ignored by some groups who start to re-invent the wheel all by themselves, not realizing how complex a system has to be to be really successful.

In passing, let me also mention that using e-Learning environments in schools and universities is rather different from using them in companies. In the latter case, they are seen as cost effective tools for in-time learning with high self-motivation of the learners, in the former they are seen as improving the teaching and easing the learning process for persons often requiring external motivation (through grading or such). It is surprising that many people do not seem to grasp that the two situations described are sufficiently different to require rather different e-Learning environments!

3. The Future

While we are still groping for the ultimate approach to e-Learning environments, technology is moving on with tremendous speed. It will not only change how we learn but much more crucial what we learn. I believe that this should be taken into account as of yesterday ☸, and much research should go into this direction. To show dramatically what will happen I will present one scenario what the computer of the future (say ten years from now) will look like. The visible part of this computer (basically its I/O device) is shown in Figure 1. The actual computer consists of an innocent looking little box (a bit larger than a box of matches) and contains:

- a high speed processor (working at 10 Giga-Hertz)
- a large internal memory (50 Gigabytes)
- an I/O device for memory cards (like the ones now used in digital cameras but with a capacity of some 100 Terrabytes)
- a mobile phone unit using fast packet-switched technology like UTMS or its successor
- a global positioning system (GPS)
- all this connected wireless (with next generation Blue-Tooth) to a device like the one shown in Figure 1.

© H.Maurer/E.Pirker 2002

Figure 1
The glasses shown in Figure 1 have a number of special features built-in: they have two loudspeakers near the back end (providing stereo sound to the wearer), they have two small mirror-like gadgets that allow to project a picture generated by the computer into each eye (thus e.g. providing full three dimensional scenes), it has a direction measurement (electronic compass) built in so that together with the GPS the computer knows not only where the person is, but what direction (at what) the user is looking. It also has a camera and a microphone (seen in the middle of the glasses) that records all that is going on, with image processing capabilities, including gesture recognition of the wearer for data input. The two spikes going upward at the end of the glasses are optional: in the future they will be able to detect a variety of states of the brain, providing a direct brain-computer interface that will further enhance facilities for data input. Much of the power of such a device is not necessary for the discussion in this paper: rather, it is the subject of a separate paper [5]. The main point is that through novel input devices (such as voice, gesture recognition as mentioned, or even input directly from the brain) users can access (through the computer) at any time both huge local data-bases and through the mobile phone future versions of the WWW, i.e. also remote ones; thus users can retrieve just about any information desired, or solve most problems imaginable, with the results communicated through 3D scenes and stereo sound through the glasses shown in Figure 1. Of course this will require advanced techniques of searching to find the relevant information, and only relevant and reliable items: this is exactly one of the main areas addressed in modern Knowledge Management systems such as Hyperwave [4]. Deeper aspects are explained in the paper [6].

Let us stop and ponder for a moment only the trivial aspects of such a situation, where information and problem solving is not just available “at your fingertips” but even more, at the “wink of your eye or hand”: in this case, external databases are very much a more or less direct extension of the human brain. How much factual knowledge about history, geography, nature, medicine (you name it) will we still have to learn when it is available any time we need it? If we want to know what we see and what the history of it is, GPS and the direction measurement will allow to give us all the information we care for; if we want to know what kind of flower we are looking at, the flower held against the camera and image processing software will give us the answer; the composition of a certain medication and all its benefits and side effects will flash on our screen when we need it. Specific first aid help will be made available to us after we have performed a computer-supported diagnosis. And, of course, the voice of someone talking in any language to us will have been picked up, translated into English and spoken into our ears, not noticeable to others. Similarly, if a problem in mathematics, or physics, or chemistry comes up, it will be easy to solve it, using the power of the computer and the databases of tools and problem solvers it has available.

Thus, what (beyond skills, like skiing, riding a bike, juggling balls, or doing a surgical operation) do we still have to learn if we have all what we usually learn available to us any time, any place? This is one of the most serious problems that will confront us faster than we will be ready to answer it: what I have outlined will be reality soon. Much of the material we learn today will not be on the curricula of future students. Yet, since it is not easy to imagine an intelligent discourse without having certain basic facts in the brain (rather than in an “external brain”) what will those basics look like?

I do hope to hear attempts of partial answers at future ED-MEDIA conferences!

4. References

To write about the development of ED-MEDIA from 1987 to 2002 is to write about the history and the developments of all of e-Learning. After all, the proceedings of the conferences contain a total of some 3000 contributions and many thousands of references to important material. Thus, discussing all this at any level of detail would require a major book, and a very long bibliography. I have thus decided to omit names and references and to only include a very few references to some of my own contributions. Anyone interested in seeing a bit more of what I have done, please visit my website. Anyone interested in more than my brief historic outline is urged to consult the proceedings of ED-MEDIA, many of them available at AACE’ s website: they
very much reflect what has happened in the last 15 years! I apologize to all my colleagues since I have not mentioned any by name, but once I would have started to include some, others would have complained with justification that I have omitted them.

PAPERS
Macromedia-Washington State Digital Design Curriculum Partnership

This partnership highlights a successful public/private partnership designed to develop the IT workforce—specifically in Web design. By working together, Macromedia and Washington State Office of Superintendent of Public Instruction were able to maximize the quality of the curriculum by focusing on teacher and student needs.

Program developers at the Washington Office of the Superintendent of Public Instruction (OSPI) knew that they wanted to develop their students’ professional technology skills. They wanted a project-based, state-of-the-art program that helped teachers teach technology in ways that engaged students in real-world learning. But they didn’t have the resources or broad expertise to build it all on their own. Many states face this challenge. They understand the problem but can’t afford the solution—without taking an innovative approach.

Knowing that corporations want to grow technically skilled workers, OSPI sought a corporate partner with whom they could collaborate on the curriculum. They selected Macromedia because it produced industry-standard professional Web design tools that their students were clamoring to learn. Macromedia was, in turn, looking for a school system that could provide valid—and vital—educator feedback from concept through to the classroom on its new curriculum.

What OSPI brought to the partnership:
- Teachers excited and willing to try something new with their students
- Cross-demographic group of schools to pilot test curriculum
- Insight into the NWCET Pathway standards
- Opportunity for change in Ed system

What Macromedia brought to the partnership:
- Expertise in technology curriculum development
- Corporate approach, and funding, to get a curriculum project done
- Opportunity for teachers to work with industry professionals
- Business people taking teachers seriously

In the last year we have brainstormed the course content, beta-tested ideas, reshaped the syllabus based on a wide base of faculty input and pilot-tested with teachers across Washington. We’ve developed a curriculum that addresses classic design principles and professional design processes, but we’ve made it approachable to teachers relatively new to technology. We’ve found that students really want to learn technology. But they need projects that are relevant to them—and they want to start right away! In this session we will talk about how to make a successful partnership, describe the benefits from business/education collaboration, and share what we’ve learned along the way.
Qualitative Analysis of Information Communication Technology Use on Teaching-Learning Process

Kanji AKAHORI
Dep. of Human System Science, Graduate School of Decision Science and Technology, Tokyo Institute of Technology
2-12-1, Ookayama, Meguro-ku, Tokyo ,152-8552
akahori@ak.cradle.titech.ac.jp

Abstract: This paper describes some of the features of Information Communication Technology (ICT) and its uses in the teaching-learning process in elementary schools. A number of articles have addressed various issues concerning the many difficulties of how to integrate ICT into the school curriculum. In most schools, it is difficult for ICT to be used effectively in the teaching-learning process. The author participated and observed many classes using ICT in elementary schools. Qualitative data such as interviews with teachers and observation of student conversations and behaviors were analyzed. The research findings were based on ethnographic case studies and are summarized as statements. The findings were summarized and are presented as a causal relation graph. The main results were: (1) Basic computer operating skills such as type writing depends largely on the classroom teacher's attitude and computer literacy. (2) Most computer operation skills such as file saving, and design skills such as designing and developing a homepage were mastered through reciprocal teaching and modeling among children. (3) Teacher's advice helps children to search and access information related to the ir topics and it was further found that to access topic relevant information was the result of a comprehensive understanding of the information domain rather than operational skills. (4) Learning motivation was highly promoted by collaborative and competitive group activities. (5) Integration of synchronized system such as videoconference into classes' needs professional technical support.

Introduction

There are many articles addressing the difficulties facing those who wish to integrate Information Communication Technology (ICT) into school curriculums. Tebbutt, M. (1999) highlights that there are various influences on the process of implementing ICT in science: the infrastructure for ICT in science, the philosophy for ICT in the school/department, and the external influences on philosophy/practice (refs. [1]). Lawson, T. and Comber, C. (1999) have also identified four factors: teachers' attitudes prior to the innovation, the role of the ICT coordinator, the attitude of senior management and the existence of adequate support and training (refs. [2]). Ertmer, P.A. has discussed two kinds of barriers on technology integration (refs. [3]), and some articles have identified that it is not easy to integrate ICT into school curriculums (refs [4],[5]), as Selwyn, N. describes ICT can be a headache for teachers (refs.[6]). Collis, B., Peters, O. and Pals, N. further detail (refs.[7]), many factors that can influence an individual's decision to make or not make use of some form of ICT in his or her learning-related activities. They highlight the four most important factors, the 4-E model, as being environmental factors, effectiveness, ease of use and personal engagement. This model was tested using statistical analysis using the questionnaire method. The author has also been engaged in research concerning the use of ICT in schools such as project study, in-service teacher training and so on (refs.[8],[9]).

In order to further investigate the factors that affect the integration of ICT in schools an ethnographic study was undertaken where the author participated in actual classes in elementary schools for a one year period (refs [10]). The chosen research approach was based on a partnership between the university and schools, which has been reported as an effective approach (refs.[10],[11]). Almost all data was gathered through interviews, informal conversations, observation of classes, meetings and so on.

Research objectives and methodology

The purpose of this paper was to find some features of ICT use in practical classes and to derive findings useful to teachers and educators in aiding ICT integration into classes. In order to conduct the research, the author visited...
two elementary schools and observed 15 classes for a period of one year. The author recorded the scenes, teachers' student conversations and the behavior of classes in field notes, pictures and videotapes, which were selected based upon the author's impressions.

In order to find the definitive variables that affect the use of ICT in classes, the author adopted the following methodology.

1. To list large-scale variables (as assumptions)
   - Large-scale variables (shown as ovals) are assumed variables and were elicited based from researchers own experiences, their pedagogical view and their view of the learning environment (See Figure 1).

2. Qualitative data collection
   - Data collection was conducted based upon qualitative research methodology. Data was collected by observation, participation of actual classes; observation of teacher's talk, students' talk and behaviors, and interviews with teachers and students.
   - Most of the data was recorded using video, pictures and notes. Lesson plans, teaching materials, the configuration of the computers in the classroom, the atmosphere of the classroom and social relations between students and teachers were recorded. These factors were often found to play an important role in the success of lessons. However, it is difficult to record inner factors such as human relations or teacher's classroom management competency through observations and interviews, even though these factors are important.

3. To pick up definitive keywords through interpretation of qualitative data
   - Keywords were added to these data. By observing pictures and videotapes, reading notes and interviews' records, researchers were able to think of many keywords corresponding to the classroom scenes that had been recorded. These are ranged from simple facts to more meaningful findings. These keywords leading to meaningful findings are defined as 'definitive keywords' in this paper and were added to the casual relation graph as sub-variables (rectangle in shape).
   - Researchers picked up definitive keywords, which were selected based upon their impression and interpretation of data.

4. To find a relation between large-scale variables and keywords
   - Researchers linked these definitive keywords to the large-scale variables based upon their judgment. Because definitive keywords are crucial, important keywords, these can be related to large-scale variables in most cases.
   - Keywords were added to the large-scale variables. All variables could be listed by adding definitive keywords to the large-scale variables.

5. To express some findings as statements and to produce a causal relation graph
   - By analyzing the data generated by the observational study, researchers were not only able to identify keywords but also identify key features of the class. Researchers attempted to investigate the reason why
teachers' and students' talk occurred, tried to extract background theory and models connected to these activities and tried to find new features of the class by comparing it to other classes.

- The extracted findings were expressed as statements these were added to our graph with causal connections being drawn to signify the relationship between one issue and another and specific examples of the observations listed below being denoted as dotted rectangles (See Figure 2).

Findings based on the observation of teachers and student activities.

Twelve findings are summarized and presented as the following statements.

1. **Keeping and memorizing a password is difficult for children.** Example: A teacher comments “Some children often forget their own passwords, therefore requesting children to change their passwords for protecting security is impossible. So, we introduced a password-card and asked the children to keep the card.”

2. **Children's keyboard typewriting skills were affected by the classroom teachers' aptitude.** A variety of skills were found amongst the children from high-level skills such as blind touch-typing to the low level skills such as one-fingered-typing. The development of these skills seemed mainly dependent on the frequency of access to computers for these children. Example: A teacher comments “There is some evidence showing the reason why children's typewriting skills are so different. Children in the class, of a teacher that often uses the computer room are generally more skillful in typewriting. On the other hand, children of teachers that do not use the computer room often are not as good at typewriting. And there is also a difference between boys and girls.

3. **A teacher's advice appears to work most effectively when talking to children individually (directly by face-to-face communication).** It is often difficult for a teacher to communicate individually with a child during a class. However, in the computer room the teacher is able to talk directly to each child face-to-face. It provides satisfaction to both the teacher and the children; it therefore works effectively from the point of view of an instructional methodology. Example: When children encountered unfamiliar material/procedures such as operations, messages or instructions from the computer, he/she asks questions to teacher, who is walking around the computer room. A teacher comments, “I was satisfied to communicate with children directly face-to-face.”

4. **Children learn mainly by observing contents displayed on the other students' screen; it is interpreted as the modeling effect.** Children show their interests when they encounter content or information different from their own thinking. When they have an interest in the information on the screen, they observe it for a much longer period of time. Through peer observations, they appear to learn a lot from each other; a type of modeling learning environment is produced. Example: When children find the content or information different from their own, they observe the screen for a much longer period of time. Children say, “This mail is much longer than the one I sent, so I am reading the mail, and thinking how to write more sentences.”

5. **Reciprocal teaching will naturally happen when they encounter the unknown.** When children encounter the unknown or find some questions, they naturally begin to talk together in order to solve the problem. And they exchange their ideas and products; this is considered to be a type of reciprocal teaching. Example: When children encountered the unknown, they asked the teacher or their classroom peers. A girl asked another child how to make a report and learnt by observing another child's product and through the exchange of ideas.

6. **Children learn more by accessing the homepages made by older children.** Children learn more by accessing the products made by children in the upper grade than in the same grade. The lesson plans that were designed to connect children to different grade children worked effectively. It appears that in these situations learning is promoted through an effect known as the zone of proximal development (refs. [13], [14]). Example: Children accessed the homepages made by children in the upper grade, and they said “How wonderful this report is, I would like to know how to make it.”

7. **On collaborative working in the classroom, the group leader's role and leadership skills including intelligence are important and crucial for leading the group through to success.** It is known that the leader's role is very important not only for group work in schools but also in general office.
work. Expert teachers, who are experienced users and instructors of ICT education, talked of the importance of the above-described findings. Example: Children producing a report through a group working activity. A child, the leader of the group, says "Be careful when saving, because we must make the file name easy to access and easily recognized by our members." A teacher remarks, "The outcome of group work often depends on the leader's power and character."

(8) Comparing and observing other group's work through a computer network brings competitive feelings to group members, and a competitive willingness promotes children's incentives towards producing a better performance.

The computer network enables children to access and observe other groups' work and performance; it leads to group members' exhibiting competitive feeling and willingness. Sometimes it is more effective to use group work to produce better products. Children learn a lot of techniques and superior design methods through group competition. Example: Through accessing and observing other group's work, children can compare and evaluate their own performance. Group members say, "Let's introduce more sophisticated techniques so that we can compete with the other groups."

(9) When group members combine the individual work made separately into one product at final stage, children show a lot of satisfaction.

Collaborative learning makes children produce a more superior product than individual learning. It also brings deep satisfaction to children especially when combining their individual pieces of work into one product at the final stage. It is also important from an apedagogical point of view. The computer network system enables to realize these learning activities. Example: Group members are combining individual work made separately into one product. They watch enthusiastically the screen displaying their product. They say "Oh, great. Let's revise here and add another picture."

(10) Technical support is needed especially when using synchronized telecommunication systems such as a videoconference system.

Most classroom teachers are not computer network experts; therefore technical problems that may occur may not be able to be dealt with by the teacher. Team-teaching such as the classroom teacher coupled with computer experts such as computer teacher or technical assistant is much more effective when conducting a class using complicated systems. To remove the classroom teacher's fear is essential. Example: A class using a videoconference system when a technical trouble occurred. Classroom teacher comments, "I cannot do anything, because I'm not computer network expert. We don't have enough time to check as to how this problem occurred." When later asked about their feelings about working with technical equipment in the classroom one teacher remarked, "My fear disappears when team teaching together with the technical assistants."

(11) Accessing desirable sites using search engines with keyword inputs is not easy for children it takes time and requires domain knowledge.

Most children would like to retrieve desirable sites using search engine with keyword inputs, but in many cases they are unsuccessful with their attempts. In order to get desirable information, children must have domain knowledge related to the topics they are searching for, not only operational skills such as how to use a search engine. Without domain knowledge, they often failed to access desirable information. In addition, it is often not easy for children to remember suitable keywords for retrieving information, because these keywords are often closely connected to the domain knowledge. Scaffoldings by teacher or other students' having more domain knowledge are required. Example: From the observation of children's activities in retrieving a site using search engines the following was found. Children that had been attempting to access topic specific sites for a long period of time abandoned their attempts to try and retrieve information using a search engine.

(12) Using a variety of resources enables children to search out information more effectively.

There are many learning resources such as the Internet, CD-ROM, newspapers, books, videotapes and so on. When children search for topic related or make reports a variety of resources that holds relevant material should be made available to them. Information on the Internet is not always reliable as is well known. At present a combination approach is required which would allow children to use the Internet as well as other resources in order to ensure an effective learning environment. Example: When children are told to produce reports as their assignments, they often go to search for additional information. As resources for investigation they can use the
Internet, CD-ROM, newspapers, books in the library, and construct a report according to their teachers' recommendations.

![Figure 2. Causal relation graph based on qualitative data analysis](image)

**Conclusion**

The twelve findings described above are represented as a causal relation graph shown in Figure 2. The important findings from pedagogical viewpoint can be summarized as the following statements.

1. Basic computer operating skills such as type writing often depend on the classroom teacher's attitude and computer literacy level.

2. Most computer operation skills such as file saving, and design skills such as homepage making are mastered through reciprocal teaching and modeling among children.

3. Teacher's advice helps children to search and access information related to their topics, moreover it was found that the access of topic related effective information is closely tied to domain knowledge a child has rather than operational skills.

4. Learning motivation is highly promoted by collaborative and competitive group activities.

5. Integration of synchronized systems such as videoconferencing in classes needs professional technical support.

From the pedagogical view, reciprocal teaching and modeling among children (2), and teachers' advice (3) seems to be more important than other findings, as it effectively highlights the different roles of novice and expert users of ICT in classes. In order to integrate ICT into classes, ICT literacy such as type writing skills, file operation skills, design skills, and a competent understanding of the learning domain are required. Integration of ICT literacy and domain understanding is essential in promoting ICT education in schools. Traditional teaching methodology is mainly based on the teacher's knowledge and their teaching strategy regarding how to transmit their expert knowledge using authorized teaching materials. However, ICT literacy can be acquired by reciprocal teaching and modeling among children without the teachers' assistance. In the classroom, there are often some children that are competent computer users because they have access to and often use a computer in their own home. These children play an important role in the transmission of skills to other children through cooperative activities. Collaborative learning among children was found to be most effective in the domain of computer skills' acquisition. This finding can be interpreted by using the concept of Vygotsky's zone of proximal development, a
concept that has previously been noted as playing an important role in ICT education (refs.[14],[15]).

Most children do however fail to access suitable Web sites. This suggests that information literacy or the ability to search for information, utilization, representation and so on are closely related to the child's knowledge of each specific information domain. The teacher as an expert of each domain can play the important role in cultivating the child's ability to strengthen their information gathering skills. It can be concluded that information literacy or capability cannot be separated from domain knowledge, and that information capability needs to be acquired through subject learning such as cross-curriculum through teacher guided assistance, while computer operation skills can be acquired through peer teaching and modeling from other children through collaborative work sessions.

Issues and Prospects of E-Learning in Oman

Abstract
The paper describes the issues and prospects of e-learning in Oman educational system. Technology has transformed the practice of education in many countries and Oman is set to modernize her education to align with the rest of the world. Several issues are receiving attention as policies are formulated and the requisite foundations are being laid in preparation for the national distance education program in Oman.

Introduction
The Ministry of Education in the Sultanate of Oman has continued to put the education of both girls and boys high on her priority list. During the Five-Year Plan 1996-2000, a total of 107 new schools were built as the Ministry has a comprehensive plan to modernize the education system to meet with the needs of the 21st Century. By the year 2000 about 565,856 boys and girls, aged 6-18 years were in schools (Ministry of Information, 2000). In 1994, there were about 3,600 students, in the various specializations at the only university, Sultan Qaboos University (SQU) with 56% females and 44% males. Only a small fraction of high school graduates get admitted into SQU.

E-learning is of interest in Oman because of the apparent inability of the only public university to cope with the large number of students who qualify for higher education but cannot be offered places. Research and experience around the world have shown that e-learning can bridge this gap. Canning-Wilson (2000) reports experts' prediction that in the next few decades, over 50% of student population will be educated using on-line learning and/or technology. What then is e-learning?

The most important concerns at this point in Omani educational development are whether or not e-learning is the best alternative in order to increase University admissions of Omani high school graduates? To what extent can policy-makers and educators trust e-learning in producing high quality university graduates? What are the criteria for assessing the quality of e-learning to accord it the reasonable credibility for acceptance? What are the issues involved in e-learning security? These concerns are, in a sense universal. A survey entitled "The States of E-Learning in the States" found that the current challenges most frequently cited by the States are the costs of developing content and training instructors; the necessary enlargement of infrastructure capacity; the quality of courses and content; agreements on articulation and residency; the responsiveness of traditional institutions; and issues of privacy and intellectual property rights. The report shows that States rank quality issues as their highest concern (NGA, 2001).

IT Status and Prospects of E-Learning in Oman
The Sultanate of Oman recognized IT as an enormous untapped wealth and began to focus her efforts in setting up IT business parks and Information Technology institutions. Apart from IT adoption in Governmental and the private sectors, educational institutions have embraced IT on a large scale. In the last few years, there had been a proliferation of the Internet Cafes in major cities of Oman and IT literacy continues to improve with many citizens using the email facilities and surfing the Web for needed information on a daily basis.

It is important that Oman is able to keep pace with the rest of the world. Al Balooshi (2001) asserts that e-learning is the "now big thing" and not the "next big thing" and that e-learning must be viewed with some seriousness in the Gulf region. On-line learning is the future of education and it is certain that those teachers who are still trapped in the in the chalk and talk tradition will be left behind as education advances into the 21st century. Canning-Wilson (2000) Further states an assumption that "Educators in the Arabian Gulf and worldwide will need to be more proficient in Educational
Technology, more aware of the theoretical and practical aspects of foreign and second language teaching, as well as increase recognizing the need to build further awareness of how teaching methodologies, learning strategies, and learning may be altered based on this new medium of on-line education”.

In Oman, the population is spread thinly over a wide geographic area. To ensure that the populace has access to the resources they need, two solutions exist which concern telecommunications. First, electronic storage and retrieval of information via the Internet will continue to erode the role, traditionally filled by books and printed media. Secondly, e-learning technologies will bring education to the Omanis by providing access to learning resources at a wide variety of locations, rather than making people travel to education. The World Wide Web offers a truly global library of a scale unimaginable and it is available equally to students studying at home or anywhere in Oman. Oman Telecommunication Company’s Internet service has struggled from time to time as demands constantly outstripped capacity. There are about 40,000 registered Internet customers and over 90,000 users. It is understood that today SQU alone has over 15,000 users. Omani students get linked with their counterparts in any part of the world through the Internet. (Al Rawahy, 2001).

Internet instructional uses by SQU faculty members are however, mostly limited to obtaining information and rich resources available at all times. This suggests that they should be trained and encouraged to broaden their use beyond the present status (Abdel Rahim & Al Musawi, 2002). Currently, there are attempts at e-learning, using the WebCT by faculty at SQU and a study on the implementation and perspectives of the early adopters has been conducted (Akinyemi et al, 2002). Omani educational system needs to learn from other countries’ experiences in her development.

Conclusions
While Oman is not oblivious of the advantages of e-learning many Omani educators will be better convinced with more research evidence on the quality, security and credibility issues of e-learning. The Omani concern for comparability of standards with the traditional system is a genuine one which must be attended to before e-learning can be developed, disseminated and diffused into higher education on a large scale. According to the call by Al Balooshi (2001) and Al Majdoub (2001), there is a need for e-learning strategic plan for the Arab world and Oman will be a fore-runner in the formulation of such e-learning strategies.

**NDU Knowledge Net:**

**A Web-Enabled Just-In-Time Information Service for Continuing Education**

Jay Alden  
Information Resources Management College  
National Defense University  
Washington D.C  
alden@ndu.edu

**Abstract:** This paper describes the development of a web-enabled information service for constituents of the Information Resources Management College. The constituents of the College, who include graduates, current students, and prospective students, typically work in the Chief Information Officer (CIO) office of United States federal agencies. The web-enabled information service, known as "Knowledge Net," is intended to tie the College constituents located throughout the world into a virtual community – sharing technical information, emerging problems, and potential solutions. Knowledge Net has evolved over a three-year span from a skunk-works project of several faculty members to an institutionalized system supported by the University. The most significant lessons learned to date include the requirement for a web-enabled content management system to ease posting of information to the website and the need to adjust administrative policy to encourage faculty to take on and integrate Knowledge Net related activities into their ongoing academic responsibilities.

**Introduction**

The Information Resources Management (IRM) College of the National Defense University is, in a sense, a Corporate University for information technology executives in the Department of Defense (DOD) and other federal agencies. The IRM College, located in Washington D.C., offers several graduate-level programs dealing with policy, strategy, development, and management of information technology systems.

One of the major programs offered by the College is the Chief Information Officer (CIO) Certificate program. This program, attended by mid-to-senior level managers in the Department of Defense as well as all other federal agencies, leads to a CIO Certificate acknowledged by the Federal CIO Council. The certificate attests that graduates of the program have received education in the skill and knowledge required of federal Chief Information Officers. Also, students completing the program earn 15 graduate-level credit hours that can be applied towards Master's Degrees at several civilian institutions. The students earn the CIO Certificate by successfully completing eight of approximately 20 graduate-level courses from ten defined competency areas: policy, strategic planning, leadership, process improvement, capital planning, performance measurement, technology assessment, systems architecture, security, and system acquisition.

Like many other corporate universities, the IRM College conducts its courses face-to-face and via an asynchronous distributed education. However, in its continuing education role for our primary constituents, the College recognized that formal courses (residential and distributed) are only one way of meeting their ongoing information needs. There are perhaps twenty thousand people worldwide serving in the CIO organizations of DOD and other federal agencies. The IRM College has the capacity for handling a maximum of 2,000 students per year. How should the College support the other 18,000 individuals? How can it better serve the graduates of its program?

These twenty thousand people are also in need of continuing development and support. They work in the field of information technology that changes radically, not just in the superficial "bells and whistles" of the
systems, but even more so in the requirements for management oversight. How will conversion to a wireless strategy change the fundamental way business is accomplished? How can the greater demand for information security be balanced with increasing concerns of information privacy? The people who work in federal CIO organizations worldwide are continually bombarded with new demands and challenges for which they were unprepared by educational programs taken just six months earlier. Curriculum development activities at the IRM College indicate that about half of the program content must be significantly revised each year. In addition, even though there is a commonality of issues through which all members of federal CIO staff must work—whether at an outpost in Korea or at a government research facility in North Carolina—each unit tends to do so individually, on its own. Historically, there has been no community by which federal CIO staff can share common problems and solutions. With the exception of the infrequent periods of time when some of them are jointly enrolled in courses at the IRM College, they are on their own—keeping up with the technology as best they can, testing out their own solutions until their next opportunity to occupy one of the limited slots for attendance at the IRM College.

The Information Service

The emergence of the World Wide Web, its growing accessibility, and rapidly developing functionality offer a supplemental approach for achieving the mission of continuing education. The model conceived to take advantage of the evolving capabilities of the Web—beyond conducting formal courses online—has been designated as the NDU Knowledge Net (http://www.nduknowledge.net/). The NDU Knowledge Net is a web-enabled service seen as an alternative Information Age strategy for the University to deliver just-in-time continuing education to its constituency. As originally conceived, it provided the following web-enabled services for each of the ten competencies identified by the Federal CIO Council:

- **FAQs**: Frequently Asked Questions and answers concerning fundamental concepts
- **NEWS**: Summary and links to recent developments concerning the competency
- **GUIDES**: Software tools, decision aids, and “How to” guidelines to do things.
- **EVENTS**: Links to training/educational programs and conferences related to the competency
- **EXAMPLES**: Success stories and sample products of real-world applications
- **RESOURCES**: Annotated links to related references on the Web

Two additional services were envisioned for the information service:

- **FORUM**: Threaded discussions on topical issues facilitated by faculty and users
- **LIVE**: Entry to scheduled real-time discussions and briefings on topical issues

The home page for the original Knowledge Net provided direct access to each of the ten competency areas (e.g., policy, strategic planning, leadership,...). Access was also provided to a search engine for searching all the Knowledge Net content, a statement of the web policy governing the Knowledge Net web site, a glossary of terms associated with the CIO position, and links to related sites.

When the user clicked on the name of a competency on the home page, the NEWS page for the selected competency area opened. From here, the users had a number of options. They could...

- scroll down the summaries of articles until they find one in which they are interested, and then click on the arrow icon to open that article in a separate window.

- open a different kind of page for the same competency (e.g., EVENTS, GUIDES,...) by clicking on one of the tabs near the top of the display.

- access the same kind of page in another competency area (e.g., Policy, Strategic Planning, Leadership,...) by clicking on one of the icons at the top of the page.

- access any of the general purpose pages (e.g., search, glossary, contact us,...) by clicking on an appropriate section of the image map in the upper left section of the display.
Each of the other kinds of pages has the same functionality as the NEWS page.

One Content Manager was responsible for each of the ten CIO competency areas. Volunteer faculty members with technical specialties in the associated competency accomplished these roles. They searched for relevant content, in part to support their normal course development and teaching duties, and in part to maintain the currency of the Knowledge Net competency web pages for which they are responsible. To assist them in this role, a pool of students doing independent study courses in related topics and research assistants was made available to them. They were also encouraged to establish special interest groups composed of other faculty, alumni, and practitioners in the field to feed them relevant sources of information. Content Manager are also provided with an account for a software agent under their control that continually crawls the web and reports back on a periodic basis with updates to its discovery of relevant content.

As the Content Managers identified items for their Knowledge Net area, they entered the required information into an electronic form designed for this purpose. Their submissions were entered into a database. At this time, items were uploaded from the database to the Knowledge Net server manually by a Webmaster, to allow for a quality control check.

The faculty member who conceived the idea of Knowledge Net served as its coordinator. His primary roles were to coordinate the activities of the Content Managers, provide quality control over the website, and serve as a catalyst for continual improvement and redesign of the site. He was supported by a Graduate Research Assistant who acted as the Knowledge Net Webmaster. Site statistics were made available from the external website hosting service, and mechanical checks on the site were conducted periodically by a subscription service looking for broken links, misspellings, and sources of excessive downloading times. Regular meetings were conducted with the Content Managers and typical users to help identify opportunities for improvement.

Lessons Learned

The initial phase of Knowledge Net development covered in this paper is restricted to the web publishing function – the posting of relevant information for users. The discussion and streaming capabilities will be introduced into Knowledge Net later this year.

In the earliest stage, Knowledge Net was hosted on a local University server. The Content Managers created and updated pages (News, Events, ...) associated with their assigned competency area using a web editor software package (i.e., Frontpage). Updated pages were sent to the University Webmaster who in turn would upload the pages to the server. This approach proved disastrous. Firstly, although IRM College faculty members are quite proficient in management concepts associated with information technology, their expertise with web editors varied considerably. The updating process required that the Content Managers first download the current page from the web server (to assure that the page being revised included all current changes), update it with the web editor, and then send it to the Webmaster for uploading back to the server. This did not always happen this way. Occasionally, a Content Manager would update the web page on his or her local drive and send it to the Webmaster without first downloading the most current page from the server. If the page on the server was a more recent version than the page on the Content Manager's local drive, this action would overwrite previous changes and corrections. In other words, configuration management of the website was a nightmare. Plus, the lack of capability with web editors by some Content Managers led to some very strange looking web pages uploaded to the server.

Another problem associated with this early stage in Knowledge Net development was its dependence on University assets – the University Webmaster and the hosting of the website on the University web server. As an experimental project of the IRM College, Knowledge Net was not high on the list of University priorities. The University Webmaster was managing multiple web projects, some of great concern to the University senior administration. It was not unusual for pages updated by the Content Managers to remain on the Webmaster's system for a week or more waiting to be uploaded to the web server while the Webmaster attended to more pressing University duties. Also, periodic weekend maintenance of the University's systems made Knowledge Net frequently inaccessible to users.
Both these problems were solved fairly easily by hiring a part-time Graduate Research Assistant as the Knowledge Net Webmaster and outsourcing the hosting of Knowledge Net to an external organization at a cost of about $200 per year. The website is now available 24/7 with rare periods of inaccessibility. The new Knowledge Net Webmaster quickly created simple web-based transaction forms and scripts to elicit new content items from the Content Managers. In this situation, a Content Manager wishing to update a page with new information accesses a web-based form customized to the type of page being updated. After entering the requested data (e.g., title, date, link, summary), the Content Manager can preview the appearance of the new item and then click on the Submit button to send it to the Webmaster. Content management no longer required the use of web editors and configuration management was completely in the hands of the Webmaster. The Webmaster was asked to upload new items to the server within three days of receipt, a requirement that was generally met except during periods of illness, vacation, and competing academic pressures on the Research Assistant. More recently, the Webmaster created a new system in which new items submitted by the Content Managers are entered directly into a database that, in turn, generates the updated web pages on the fly. In other words, as soon as a Content Manager submits a new item, it is immediately displayed on the Knowledge Net website. Content Managers now also have the ability to edit and delete items from the database themselves. They are now, indeed, content managers.

Another problem led to a major overhaul of the Knowledge Net website this year. Up until recently, the Knowledge Net areas (e.g., Strategic Planning, Capital Planning,...) were based on the ten competencies originally specified for Department of Defense CIO’s. As such, ten IRM faculty members were recruited to serve as Knowledge Net Content Managers, one for each competency. The selected faculty members undertook this new incremental task with varying degrees of enthusiasm. Some were highly excited about the prospect of managing a portion of a website devoted to a content area associated with their own intellectual pursuits. These faculty members saw their content management responsibility as an opportunity, spending several hours a week in the search for new relevant content, publishing new items almost every day, and integrating the website into their academic courses as a major information resource. However, other faculty members were more reluctant to embrace their content management responsibility. They seemed to see their role in Knowledge Net as a burden, almost a distraction to their ongoing academic duties. As a result, the content on web pages associated with these competency areas might not be updated for weeks on end. This is a serious problem for a web-based information service such as Knowledge Net. Websites of this sort must have fresh content in order to attract and bring visitors back. At the request of the Knowledge Net Coordinator, the College administration granted teaching load credit for Content Managers. It was hoped that the ability to reduce teaching hours in return for work done on Knowledge Net would both free up the necessary time and serve as an incentive. Moreover, the granting of contact hours gave recognition that Knowledge Net was a legitimate and important service of the College. Unfortunately, this management action had virtually no affect on the frequency with which web pages of the various competency areas were updated. The pace of activity on Knowledge Net by both groups of Content Managers – those who saw it as an opportunity and those who saw it as a problem – went on as it was.

The proposed solution to this issue led to a redesign of Knowledge Net. The number of competency areas has been collapsed from ten to six and these six areas are now aligned with the organizational structure of the College. The six areas are now e-Government, Performance Management, Enterprise Architecture, Systems Acquisition, Technology Capabilities, and Information Assurance. Each of the three academic departments in the College now has responsibility for two Knowledge Net areas, and two of the areas - e-Government and Information Assurance – are each aligned directly with a center of excellence at the College. Department Chairs at the IRM College have supervisory responsibility over faculty (i.e., they play a prominent role in hiring, contract renewal, work assignment, promotions, and bonuses). The redesign was based on the belief that a more consistent level of performance will be attained by reducing the number of required Knowledge Net Content Managers (i.e., it should be easier to find six personally motivated faculty members than ten such individuals) and by delegating their selection and management to the Department Chairs. This change was initiated about three months ago and, although performance has been more consistent, it is too early to declare a success. Everyone is still exploring the requirements and practices of his/her new responsibilities.

The redesign of Knowledge Net also involves the following changes that are expected to be completed by the end of 2002:

- Redesign of the pages for a common look & feel consistent with a new IRM College website.
- Reduction in the number of kinds of pages for each competency (Basics, Articles, Events,
Documents, Websites), which are easier to distinguish among than the previous page types.

- Introduction of a more powerful search engine.
- Addition of a threaded discussion capability to be facilitated by the Knowledge Net Coordinator, with the voluntary assistance of other Content Managers, to enable users to share field problems and solutions with each other.
- Ability of users to suggest sources and items for inclusion into Knowledge Net.
- Presentation of scheduled lectures by faculty and guest speakers of the IRM College using streaming video.

Conclusions

The existence of Knowledge Net offers a number of benefits to the College and its constituents.

Benefits to the Constituents of the College

Knowledge Net enables the 20,000 thousand people working in federal CIO officers to continue their professional development, even when they are unable to enroll in formal College courses. They have access to current information about the field anytime and from anywhere – information that has been selected and filtered by faculty experts in the CIO competency. When the full functionality of Knowledge Net comes online in 2002 with streaming video and discussion boards, users will also be able to hear and see guest speakers at the College talk about advanced topics related to the field, and discuss issues with faculty, peers, and experts around the world.

Moreover, Knowledge Net benefits the College’s constituents by helping improve their job performance – it serves as a kind of electronic performance support system. Users can stay abreast of late breaking news concerning CIO responsibilities. They can more easily find resources to help do their jobs, just when they need them. Using the discussion boards, they can note how things should be done and how others are actually doing them – noting what works and what does not. They can even collaborate with others doing the same kinds of things no matter where they are doing them.

Benefits to the Institution

The mission of the IRM College is to “prepare military and civilian leaders to direct the information component of national power by leveraging information and information technology for strategic advantage.” Note that the mission says nothing about preparing these leaders by means of educational programs. Knowledge Net is an alternative means to accomplish the College’s mission, one that is likely to play an even more prominent role in the future.

Knowledge Net also benefits the College by strengthening its relationship with its constituents. Certainly, the information available on Knowledge Net is a resource available to students currently enrolled in courses, both residential and online. It provides a searchable database of relevant information useful for papers required in the academic programs. As mentioned previously, Knowledge Net is also available to graduates of our programs for continuing education and development. Alumni thereby remain connected to the College long after graduation. Knowledge Net can even be used to promote the College programs. Many of the 20,000 people working in federal CIO organizations are unaware of the IRM College’s existence and the availability of the CIO Certificate program. If Knowledge Net is perceived as a useful tool on the job, its association with the IRM College can continually attract new students.

Implications For Other Organizations

The Knowledge Net strategy being developed by the IRM College seems to have value for other corporate universities, provided they see their missions as developing and supporting the job performance of constituents, rather than just conducting training and education courses. In a similar vein, professional
associations whose members share a common set of competencies can also apply the strategy. Even subject-specific centers of excellence resident in institutions of higher learning can implement a Knowledge Net-type website to benefit both their constituents and the center itself. In fact any organization seeking to support constituents with a common set of competencies and that possess a group of specialists who are willing to adapt web technology to serve their role can implement a Knowledge Net strategy.

Integrating Handheld Technology and Web-based Science Activities: New Educational Opportunities

Turadg Aleahmad, Jim Slotta
Graduate School of Education
University of California, Berkeley
United States
turadg@wise.berkeley.edu

Abstract: We describe the integration of handheld computer technology into an existing web-based educational platform, the Web-based Inquiry Science Environment (WISE) and the synergy it produces. This solution facilitated a research program that explores how handheld computers (PDAs, palmtops, etc.) can expand the scope and functionality of inquiry activities in K-12 science and mathematics curriculum. We present the WISE software and curriculum and explain how combining it with handheld technology creates unique educational opportunities. We then describe the system we have developed and its future.

Introduction

This paper will present an innovative application of handheld technology for science education. For the past seven years, the Web-based Inquiry Science Environment (WISE) project, funded by the National Science Foundation, has explored the most effective designs for inquiry activities that draw upon the wealth of Web resources. We have designed an effective browser-based learning environment that scaffolds students as they work collaboratively on inquiry projects.

The designs of the WISE learning environment, inquiry curriculum and assessments are based on a pedagogical framework called Scaffolded Knowledge Integration. This framework, developed by Dr. Marcia Linn and her colleagues (Linn and Hsi, 2000), has been developed through twenty years of classroom research with technology and inquiry (Linn and Songer, 1982, Bell, Davis and Linn, 1995; Slotta and Linn, 2000).

Continuous improvement of the WISE technology has resulted in easy-to-use software that scaffolds students as they perform critique, design or debate projects. A growing library of such projects has been developed by "WISE Design Partnerships" that include scientists from agencies like NASA, NOAA, and The National Geographic Society. Over the past several years, both our curriculum library and user base have grown dramatically. Thousands of teachers and many thousands of their students now use WISE inquiry projects in their science courses.

We have begun to research the challenges faced by science teachers as they adopt the innovative technology and inquiry methods provided by WISE. To that end, we have formed partnerships with two large school districts -- Denver Public Schools (Colorado) and Desert Sands Unified School District (California). Working closely with administrators within these districts, we have helped science teachers integrate WISE activities into their courses, and developed networks of WISE mentors in the districts to support them.

Together with these school district partnerships, we were recently awarded a grant of 500 Palm IIIc handhelds from the SRI Palm Education Partnership to design effective uses for handheld technology in education. Our goal was to develop Palm activities that would complement our existing library of Web-based projects, benefiting from the scaffolding of the WISE technology and curriculum. We sought to integrate the use of handheld computers with WISE curriculum, enabling both data collection activities like surveys and field observations and further, reflection activities in analyzing the collected data.

In this paper we present an overview of the WISE environment, detail the goals of our handheld technology initiative, and describe it functionally. We then present our experiences with its use to date and look toward the future.
WISE: The Web-based Inquiry Science Environment

WISE offers a powerful browser-based learning environment for middle and high school inquiry science projects. Students work collaboratively in these projects, actively using materials and software from the World Wide Web. In one project, students evaluate the health of a local creek, modeling the factors that contribute to pollution. In another, they compare two competing theories about why deformed frogs are appearing in American waterways. Figure 1 shows a screenshot of the WISE learning environment and Figure 2 shows the growth of our user base. An inquiry map on the left-hand side of the browser window coordinates all student activities, resulting in Web materials, pop-up notes or hints (shown in the Figure), or any of a variety of other tools and features, such as online discussions, journals, causal maps, data visualizations, and an argument editor. Throughout the project, the inquiry map scaffolds students as they work collaboratively to perform carefully designed inquiry projects.

Figure 1 WISE user interface, notes, hints Figure 2 WISE user signups in past 2 years

WISE projects are designed to offer teachers a means of adding inquiry and technology to their existing curriculum. Teachers choose from a library of projects, each accompanied by a lesson plan, assessments, scoring rubrics, connections to standards, and opportunities to customize the project to local issues and curriculum topics. Teachers can monitor and grade student work, provide formative feedback during a project run, and manage their student accounts. The reader is invited to visit http://wise.berkeley.edu/ where she will find more than 30 different projects, in topics of physical, earth and life sciences at grade levels from 4 through 12.

We have researched the effectiveness of WISE activities for student understanding in a wide range of classroom studies, summarized in a recent book by Linn and Hsi (2000). All WISE activities are assessed by pre-post test items, as well as embedded assessments, which show that students develop a deep understanding of the science content, and gain important lifelong learning skills related to critique of evidence, debate of arguments, and design of personally relevant solutions. WISE research has demonstrated an impact on student understanding of science, fluency with technology, and literacy in the use of language and argumentation (Linn and Slotta, 2000).

Goal of project

We seek to leverage the strength of the WISE platform and curriculum to provide effective new applications for handheld technology. Our innovation focuses on two main affordances of handheld technology: 1) convenient and portable data creation, 2) portable dynamic content. Within the scaffolding and instructional context of the WISE learning environment, these become powerful pedagogical instruments.

For example, working in the Genetically Modified Foods project, students download a carefully designed survey into their handheld, and then interview their friends and family between classes or after school (e.g., collecting age, gender, dietary habits, and beliefs about GM Foods). Later, they put them in the syncing
cradle and all their data is transferred to the WISE databases. This provides collaborative data for the students to draw upon as they continue to debate whether GM foods are dangerous.

By facilitating data collection, we enable useful analysis. For example, in the Healthy Creeks project, students take measurements of the chemistry of the creek and input it on-site automatically with probeware or manually with the stylus. In the classroom, they analyze the variance among their class and how it relates to other classes. Using the data analysis tools, the students can explore the data. For example, comparing the average pH of the creek each month for the past 2 years. (The Creeks project will be presented in detail below.) Such activities empower the handheld with the context of a broader curriculum.

System description

In the course of bringing our vision to handhelds, we have developed a versatile collaborative database that can be used to collect and analyze any sort of data in any context. To explain, we will describe a mock application from start to finish.

Remember that a WISE project consists of steps that the student navigates through using the inquiry map (far left of Fig 1). To bring collaborative data into a WISE project, the author adds a step from the Data Collection / Analysis family. We begin by selecting the “Form blank” step (Figure 3). A form blank is the empty form that is to be filled out.

Within the form blank authoring window, we author the form blanks for this project. A form blank is comprised of a sequence of form fields. A form field is comprised of a prompt and a data input definition. Data input types include text, numbers, radio buttons, checkboxes, pop-up menus, lists, etc. To define a form field, the author chooses the type and then sets the parameters of that type. For instance, if it is a checkbox field they will define the choices and optionally include an image to represent each choice.

For the sake of explanation, let us author a form called “Fishies”. It consists of three form fields. The first has a prompt of “Which tank did you watch?” and a pop-up menu to choose between Main, Tropical, and Arctic. The second, “Which fish did you watch?” lets the user choose images of a guppy, a tuna, and a shark. The third, “How many did you count?” lets the user input a number.

We also add a “Form analysis” step. Here we choose which fields to analyze. We also choose the scopes of data to include in the analysis: just the group’s data, the whole class’s data, data for all users of the project, data for all projects. (A form field, once defined, can be reused in any form blank even across different projects.) We also choose what data filters to offer to the student in order to guide their reflection. Filters can omit or include responses that meet certain criteria, such as temporal range or response to a field.

For our project, let us choose to analyze the fish count based on the tank and fish that the student watched (Figure 4). Now we have our collaborative data collection and reflection working in the web browser (Figure 5). This is all well and good, but we want the students to have Figure 5 on their handhelds. To do this,
we go to the handheld setup page of the authoring environment and define channels to send to the handhelds. A channel is a selection of form blanks to fill out preceded by introductory text, much like a WISE project step. It is separate so that the author can differentiate the tasks to perform on the handheld from those to perform in the browser. (An in-class form may have the students make predictions and on-site collect the true data.)

Once we have defined the channels, we click to subscribe the handhelds to them. We currently make use of a service called AvantGo to transfer the data. (AvantGo is a commercial service and may not suit us in the long term, but because we have built our system on open standards we can easily shift to other services or create our own.)

Once this is done, the students put their handhelds in the cradle and let them sync with the WISE servers. This downloads the channels and form blanks for them to fill out. Each set of handhelds shares one AvantGo account. The account lists the channels that have been subscribed (left Figure 6). When the student picks up their handheld for a WISE project, they select its channel. In our example, "EdMedia Demo". They are then presented with the instructions and list of form blanks that the project author specified (right Figure 6).

In our example, they select the "Fishies" form blank. (Figure 7 shows how this form blank appears on an actual Palm IIIc, in contrast to the web browser in Figure 5.) The students then fill out the form wherever they may be. Since the handhelds are shared by the whole class, each student signs their form with their name in order to receive credit. (Any illegible or no-name work is sent to the teacher’s management window to reattribute.)

When they return to the classroom, the students drop their handhelds in the cradle to submit their responses to the WISE server. Then they return to their web browsers to explore the data and reflect. The inquiry map guides them through this exploration. Within a Form analysis step they experiment with the parameters of the filters. The system then renders the data for the subset they have defined. (Figure 8) This is how the students mine the meaning out of their data.
First Trip: Aquarium

But how does the technology work in the real world? Our first trial with students confirms that it does work in real classrooms. In partnership with the Monterey Bay Aquarium, we developed an inquiry project to help "extend the visit." (Figure 9) Before the trip, the project led students to ask themselves questions that helped their investigations during the aquarium visit. During the trip the handheld forms prompted the student for data to collect. After the trip, the students worked through the analysis steps of their WISE project to help make sense of their observations and integrate their field experience with the classroom curriculum.

Educators from the aquarium wanted to help students focus on marine science concepts, including the factors relating to fisheries decline. We co-designed an activity where students explore the fish in Monterey Bay, reflecting on why some fish are placed on a "Seafood Watch List" while others are not. Students chose one fish for specialization, which they investigated at the aquarium. The forms prompted them to record observations about the fish and other features of the aquarium. We designed an observation form that would help students reflect on the habitat and adaptations of "their fish," as well as a checklist of aquarium activities that was beamed to students by aquarium docents. These observations provided a focus for student activities at the aquarium while enabling the collection of student data for use in later stages of the project.

When we ran the project with students from an oceanography club at North Salinas High School, they embraced the handhelds even more quickly and easily than we had expected. After a few minutes, they had no difficulties navigating the forms. They became adept quickly at inputting text using Palm's special system, Graffiti. But most importantly, we came away with new ideas to improve the system. In their next trip to the aquarium, students could refer to on-line guidance while using the Palm. If they did not understand a term, they could click next to it to view a glossary. If they did not know where to find what they were looking for, they could click another button to pull up a "field guide." In this way, handheld technology can bring the aquarium to the classroom and the classroom to the aquarium.

Second Trip: Creeks

Our second major run was using the Healthy Creeks project, mentioned earlier. In this project, students visit their local creek and use chemical tests to take real measurements. They collect data from several sites and then upload them all back at the classroom.

These students were from Foothill Middle School. Even these 6th grade students had little or no difficulty navigating the forms and entering data. Furthermore, they were visibly excited to learn that they would be using the handheld computers. "Do we get to use those?!" We discovered that the cool factor of the technology motivates many students like nothing else could.

Future
Our future research is to further explore the pedagogical value of the technology. One experiment in development is to study several classrooms of students at the Monterey Bay Aquarium, only some of which will use the handheld computers. To evaluate the impact of the technology, we will observe how the activities at the museum and the take-home learning differ between the groups.

We also plan to bring a handheld component to our longstanding Genetically Modified Foods Debate project. Currently, eighth-grade students engage in a two-week inquiry based curriculum on genetically modified foods. Students learn to weigh the tradeoffs involved in using one method of agriculture or another, as well as to support their position with appropriate evidence. Students are given many opportunities to express their ideas, and learn from each other while debating the controversy over whether GM foods are safe for human consumption. With handheld forms, students will be able to extend their own investigations beyond the classrooms and into their social networks. Back in the classroom, they can visualize the data and compare based on criteria they choose. Additionally, they will be able to incorporate and compare responses from their teacher's other classes, or from classes in another district, state, or even country.

We also seek to understand the effects of bringing learning into a social context. In the process of surveying, we expect students to learn to evaluate information sources, to synthesize from observations, to interview effectively, and to reflect on their role. We believe that they can develop a coherent understanding by first asking people what they know, discussing the issues with them, and then researching the relevant facts and concepts independently using WISE. We want to know how the use of handheld technology can improve students' general inquiry skills.

From the technical side, we plan to research the data representation component itself. We are developing many different visualizations and comparison schemata for the data and in the process of evaluating their relative effectiveness. And more specifically, what representations are most effective for what pedagogical goals. The challenge is to develop software that is 1) flexible, 2) intuitive, and 3) works well on the computers found in most classrooms. Even further down the road, we plan to streamline the technology and make it even easier to administer. We envision a turn-key solution that a school can place in the computer lab. This box would track and manage each handheld device and help the teachers focus on teaching.

Conclusion

The WISE learning environment and handheld computing are synergistic. The handheld provides the mobility necessary to collect real-world data and observations and to bring dynamic content outside the classroom. WISE provides the scaffolding to give these data pedagogical value. By integrating them, we have created the exciting education opportunities described and certainly even more opportunities that we have not yet imagined.

Musical Improvisation: A Model For Infusing New Technologies Into The Design Of Instruction

Panel Position (shared by the four panelists):

In an age of rapid change and almost unlimited opportunity for continuous technological innovation in schools, traditional communication and decision-making systems characterized by structure and linear process must be made more responsive. Lessons from jazz and other forms of musical improvisation can help schools develop new approaches to discussion, decision-making and experimentation which will allow schools to more fully engage technology and new educational practices, thus better meeting the often complex expectations of a diverse range of stakeholders.

Each panelist brings a unique perspective to this topic:

Dwight Allen, is Eminent Professor of Education Reform at Old Dominion University and former Dean of the University of Massachusetts School of Education. A recognized thought leader in the field of education innovation for more than four decades, his latest book on education reform, co-authored with Bill Cosby, was published as one of Time-Warner's first e-books. The book was a finalist in the Frankfurt Global E-book Awards, sponsored by the International E-Book Award Foundation this past Fall.

Carl Hoagland, holds the Emerson Electric Endowed Professor of Technology and Learning at the University of Missouri, St Louis. He is also the director of the E. Desmond Lee Technology and Learning Center. With over 35 years of experience in all levels of education as teacher, consultant and professor, he specializes in the application of new technologies as learning support tools.

Douglas Allen is Associate Professor of Management at the University of Denver. Former MBA Course Coordinator for the Daniels College of Business High Performance Management course, he has participated in a wide range of educational innovations at the University of Denver. A frequent consultant to Fortune Global 500 companies in the US and overseas, he has written and conducted research on a variety of topics related to change in domestic and global companies.

Gwendolyn Watson is concert cellist, composer, improviser and teacher. Described in a New York Times review as a “zany but serious musician,” she has performed in some of the great concert venues of the world and continues a life-long ambition to extend musical appreciation to the general public.
More complete bios are attached at back of proposal.

Description of the Panel Topic

In the current age of technological frenzy with its promises of new potential, enhanced options, vastly increased choices (and occasional cacophony), educational practitioners are bombarded with so many opportunities for innovation, that it is very difficult for them to know how to respond. Adding to the confusion, equally impressive developments in both cognitive and neurological learning sciences suggest that the very processes of education can be restructured to improve effectiveness. Further complicating this instructional melee is increased public and policy-maker demand for accountability.

In this turbulent environment, traditional organizing and decision-making systems are being taxed to their limit. Perhaps we are in need of some new organizing principles – a new approach to sorting out the complicated opportunities and demands imposed upon educators by a diverse range of stakeholders.

What we will demonstrate

Dwight Allen, Eminent Professor of Education Reform at Old Dominion University, and Carl Hoagland, Emerson Electric Endowed Professor of Technology and Learning will join participants in an exploration of the power of musical improvisation as a metaphor for decision-making and experimentation with the infusion of technology into educational processes. Specifically the use of improvisation will be examined as a tool from the perspectives and for the use of: educators, students, parents, technologists, as well as software and materials developers.

The panel will identify four roles in improvisation: to lead, to follow, to reflect (wait out), and to redirect. In this session, we argue that members of an education system (whether elementary, high school or university) can become individually and collectively more effective by building capacity in each of these four skill areas. Through impromptu musical participation (utilizing a variety of hand-held musical instruments from around the world) by the audience - led by world-famous cellist Gwendolyn Watson - the session will explore how technology can shape and be shaped by each of these roles.

Referencing the work of Kao (1996) and others, Douglas Allen, associate professor of management at the University of Denver, will show how traditionally emphasized economies of scale in organizations including schools may need to be supplemented with an emphasis on economies of discovery. The theory of scale economies has emphasized efficiency through standardization – often achieved through high degrees of linear structure. While these are certainly still important, they are no longer sufficient. To fully prepare students to be effective participants in the new, information and technology rich environment, an emphasis on creativity, innovation and spontaneity is required as well. By adopting improvisational behaviors, schools may become more open to the approaches that can effectively prepare students for life in an
information-rich society and model the very capacity for change and openness that our students must learn.

Throughout the session, we will demonstrate how the principles of jazz and other forms of musical improvisation help us find “the sweet spot” between precise scripting of learning and the chaos of random response, and what this means for the adoption, development and use of technology in schools.

Context

We will facilitate our session as an emergent mix of content-oriented discussion and experiential exercise involving session participants in musical improvisation—taking time as we go, to discuss the takeaways of each improvisational experience. The exercises will provide a metaphor for the discourse that could effectively take place in schools, helping them to become more open to technological change. Through the experience offered in this panel, session participants will discuss and explore first-hand, how having a multitude of resources available-sometimes without coordination, but with the awareness of the availability and utility of each-can enrich the instructional environment by facilitating and encouraging impromptu experimentation, trial and adoption of new technologies and the new pedagogical approaches they may allow.

Abstract

WQ is a Web-based system which reflects some of the ideas found in WebQuests. We intend to analyze the characteristics that make the WebQuests so popular and determine which of their components give them the greatest educational value. The WQ system which we have implemented presents sites to be browsed and searched, it allows students to make notes on those sites, and it lets the students manage those notes to respond to the Quest. Ultimately, we hope that the WQ system will incorporate collaboration, integrate digital libraries, be scalable, and support a wide variety of content areas.

1 WebQuests

WebQuests are Web-based learning activities that have become very popular with both teachers and students [6]. Students are given questions to investigate and Web-based resources to use in answering them. The students produce answers to the questions that include references to the resources. WebQuests are closely related to other systems for inquiry-based learning such as ThinkQuests [18] and Internet Quests [5]. In a larger view, they are related to e-books [9] and digital libraries.

1.1 Variety of WebQuests

WebQuests are not a single, simple educational approach but a collection of related approaches. The essence is that students synthesize answers to questions based on Web resources. These resources may be either public Web sites or sites custom-designed for the Quests. Types of resources may vary greatly depending on the educational goals and the resource familiarity of both teachers and students. Some WebQuests also require cooperation among teams of students.

1.2 Underlying Skills

WebQuests are a type of inquiry-based learning [2, 7, 10, 19]. WebQuests combine many layers of skills. At a low level, the student must pick out material that is relevant to the question. This is similar to the challenge of reading comprehension [13, 14]. There is also the challenge of navigating the text on the page via cognitive organizers [8]. At a still-higher level, the student must engage in problem solving to determine where to find the best material. There are aspects of "active reading" in note taking (e.g., [12]) and in the management of the notes.

1.3 Digital Libraries and WebQuests

A WebQuest may be thought of as a very simple digital library which the student has to search. We take that analogy literally and attempt to combine digital library technologies (e.g., [3]) and educational strategies. Digital libraries can support teachers in creating a collection of works for the students quest. The student then navigates within the collection. Various different strategies can be applied in scoping the collection, such as appropriate levels of scaffolding.
2 The WQ System

While current WebQuests generally require the student to write essays either by hand or with a word processor, it is useful to develop a completely integrated framework. In this case, rather than writing essays, we simply ask the students to make notes on a selection of articles. These notes can then be arranged to present a response to the question. WQ provides a single interface for the associated activities of searching, reading, and writing.

The main control for the WQ system is via a tree widget which is presented in the left frame. This widget lists several Web Quests and for each Quest it presents background information and separate questions. In the present version, the basic paradigm for student interaction is creation of notes on the texts provided. The collection of notes taken together represents the student’s response to the questions. Later, we propose models for extending this interactivity.

![Figure 1: The Quest Manager (left) allows selection of Quests and questions within those Quests. Recommended Web pages (right) can be accessed either by browsing or via search.]

2.1 Selecting Web Pages

The right side of Figure 1 shows the screen for presenting the list of web pages that have been recommended by the teacher for a particular WebQuest. While the current five articles are small enough to be browsed, we have also implemented a search feature that will be useful for larger collections which may be more properly thought of as digital library collections. The search utility allows teachers to provide a controlled domain of material, supporting the student by narrowing the field of resources but still providing an environment of exploration.

2.2 Making Notes

The students interact with the Web sites by selecting relevant sentences. Specifically, the students click on sentences to annotate them and to add those annotations to the list of notes. This is illustrated in Figure 2 which shows the highlighted text and a box for adding the note title and body. The main paradigm we wish to explore with this first version is linking into the text of documents. However, the current implementation allows access to any Web page in addition to formatted documents. For these Web pages, the notes can be posted only at the top of the page. In the future it may be possible to attach notes to particular passages as with the formatted docs.

2.3 Notes Manager

All of the student notes are collected into a single list as shown in Figure 3. The student can arrange the order of the notes to respond to the questions. In particular, notes are managed by selection of the note with a radio button and the selection can then be moved up/down or right/left in an indented hierarchic list. Integration of the notes manager with the browsing utility allows the student to respond to questions in the quest with out leaving the browsing environment.
Big Al - lone scavenger or social I. comment

Big Al (Allosaurus fragilis) was the main carnivorous dir.
teeth - a formidable Idling machine and a ferocious hunt

http://126.6.224.2Internet

We can't go back in time we have other clues as to how they behaved relatives such as birds and crocodilians to find similar behaviours. When we observe most birds, both behaviours are observed. We see but others have a minimum amount of contact with their own species. Crocodilians are generally solitary by nature. The main interaction is mating and defending territorial boundaries. Mother alligators are caring and protective of their young only while they are small. Once alligators will happily make a meal of them. Can we apply the observations of birds and crocodilians to dinosaur behaviour? Like their social or antisocial depending on circumstances of age, population dynamics or availability of food.

North America. Aliosaurs were made for r

Figure 2: The student can create a note by clicking on a sentence from the text. This screen shows a frame with control buttons, a text with a highlighted (selected) sentence, and a note-entry box.

2.4 Implementation

This implementation uses a frameset which includes HTML, Javascript, and Java. In order to add notes by clicking the text, we built a Java applet for the presentation of the text. This also meant that specialized Web pages had to be constructed. This is in the spirit of WebQuests that have tailored Web pages. The text of five Web pages from [4] was selected and reformatted for presentation via the Java applet. A future implementation may be adapted to automate reformatting either in batches or on the fly. The login control, recommended site listings, and notes are all managed with Perl scripts which connect to a Postgres database.

3 Digital Library Resources for WebQuests

WebQuests depend on high-quality content for the students to access. This information resource may range from a single Web page to a large collection of Web resources. We treat the Web resources as a scalable digital library. We have recently completed work on a digital library for The Maryland Electronic Learning Community (MELC), a part of the Baltimore Learning Community (BLC), has focused on the creation, maintenance, and cultivation of a digital library for teachers in five middle schools in the Baltimore area [16].

OAI, the Open Archives Initiative, has developed an open protocol supporting free sharing of metadata among diverse digital libraries. Using the OAI open protocol and an XML interface provides navigable access of the metadata from the MELC digital library as well as other digital collections. The OAI protocol [11] was initially developed within the e-print community with very task specific feature sets. Early directions evolved to open the standard and lower the barrier to entry for non-e-print collections. This opens the door to a great many potential resources for Web Quests. With further development, WQ could be expanded to take advantage of any OAI compliant resource. Here we see a different balance being struck between specificity and generality. Building on that foundation, information providers have a great deal of freedom to develop specific enhancements. The approach has great strength in that it offers one of the first structured protocols for metadata sharing. Our system uses XML to provide a minimal foundation of interoperability.
4 Future Directions

We will extend the initial work to incorporate additional features including (1) access to video and other multimedia resources, (2) support for collaboration, and (3) the ability for the teacher to harvest resources and evaluate student work in progress. We will also systematically examine the use of Web-based online resources in inquiry based-learning. Ultimately, students could have flexible resource management desktops (e.g., extending the ideas in [1]) and the underlying model could allow flexible interaction among the components.

4.1 Multimedia and Collaboration

We will incorporate videos as information resources, add the ability to jump to specific frames of the video, and we will develop simple summaries and indexes for those videos. The WebQuests of students with different multimedia indexing and access tools will be contrasted. Some existing WebQuests include multimedia, but that multimedia is not seamlessly integrated with the Quest. Because XML is rapidly being extended to encompass multimedia, our XML-based framework should be able to leverage that work. Similarly, simulation may be added.

Collaboration often makes learning more engaging [17]. Our existing annotation facility can be extended for use by several students at one time. We will extend the current model by adding features to give each student the ability to have distinct annotations and resources while also being able to read and comment on the work of the other student(s).

4.2 Teacher's Interface

While we have focused on the student's environment for completing WebQuests, it is also possible to support the teacher while they build the WebQuests and while they interact with the students who are completing the WebQuests. The teacher's needs in many ways mirror those of the student interfaces.

The teachers in the Baltimore Learning Community have found WebQuests to be highly effective. Building a WebQuest, as well as many lesson plans, requires identification of useful and appropriate Web materials. Selection criteria for inclusion in a lesson plan generally hinge on readability. Many teachers report that the challenge is to find the right digital collections. There has to be enough text, at the appropriate reading level, but not too much to be digested. When teachers find these resources, it would be helpful if they could manage them in personalized collections with annotation capabilities.

Moreover, teachers are looking not just for evidence in support of lesson objectives, they must simultaneously screen for appropriate presentation. In building a WebQuest, the teacher plays the role of collection builder for the student. A collection that covers the topic being studied but presents it at an inappropriate level is of limited use.
The materials in an OAI compliant collection can be a resource of great value to teachers. The Open Archives Initiative also provides open access for "harvesting" collections, but the protocol alone is not enough to make the data useful. We have explored metadata sharing via the OAI in light of teachers' needs in the BLC. We find a need for a system that allows users to integrate collections of annotations of, and associations between, Web resources. For instance, tools built on top of the OAI architecture could allow teachers to add value to the metadata or resources they find.

We find in usage analysis that many of the same materials within a very diverse collection are reused, not necessarily because of their content but because of "word of mouth" [15] and the barriers to easily finding alternative materials. One of the greatest obstacles teachers face is the ability to obtain and interpret organized collection data. Teachers find an overwhelming amount of resources on the Web. But the transition from collection to collection can be a somewhat nomadic process. Teachers use words like "hunting" and "searching" when describing the process of obtaining task-appropriate materials from multi-media sources and digital libraries.

Finally, teachers could also monitor the progress of the students and, eventually, could even provide interactive suggestions to the students while they worked, using the WQ interface. We envision the computer as a support for the teachers to track the progress of individual students. WQ could be extended to help teachers identify which students need the most help with a particular Quest.

5 Conclusion

Although Web Quests are very popular, their educational value is not well understood. We have developed the first stage in a unified environment for managing WebQuests. The current system allows the students to attach notes directly to texts. The collection of the notes allows the students to respond to the questions. This is not the final version of this system; we are close to completing access to multimedia and support for collaboration in note taking. We anticipate that WQ will become a successful model for an integrated WebQuest interface.

How are Learning Objects Used in Learning Processes?
Instructional Roles of Learning Objects in LOM

Heidrun Allert, Hadhami Dhraief, Wolfgang Nejdl
Learning Lab Lower Saxony, University of Hanover, Germany
{allert, dhraief, nejdl}@kbs.uni-hannover.de

Abstract: In order to reuse and exchange learning objects we need information about these learning objects. The LOM draft standard defines a set of more than 70 attributes, which specify learning object properties like author, title, subject, and many others. Even though the LOM draft includes a category educational, no information is included in the standard to specify, which instructional roles are played by a learning object in a course. We show how to include this important didactic information using the concept of instructional roles and relations in a way, which is extensible and flexible enough to specify not only general didactic criteria, but rather specific criteria, as prescribed by different instructional theories.

Motivation

To allow the reuse of learning objects (LO), various standards have been developed to describe learning objects, their relationships, etc. The IEEE LOM Draft Standard for Learning Object Metadata (LOM2001) specifies a variety of bibliographic and technical properties of LOs, as well as different relationships between LOs, and make exchange, reuse, and search of LOs based on these metadata possible. Even though the LOM draft includes a category educational, no information is included in the standard to specify, which instructional roles are or can be played by a LO within a course. As curriculum programs do, LOM concentrates on what should be taught and when, rather than how to teach. Obviously, a standard for learning objects metadata should not tell how to teach, but it should definitely be able to provide information on how to specify pedagogical aspects of LOs. This difficulty is caused by the fact, that LOM attributes specify properties only at a very basic abstraction level. LOM specifies annotations for content and activities but does not support metadata about instructional models and theory, even though authors are implicitly or explicitly using specific instructional theories. LOM does not support information about the use of LOs in learning processes, which are a central concern in instructional design. The current paper introduces additional abstraction layers to the LOM specification which explicitly takes different instructional theories into account.

The Current LOM Model: The Learning Object Metadata Standard (LOM for short) defines a structure for interoperable descriptions of LOs. It aims at facilitating search, management and (re)use of LOs by authors of online-courses, teachers and learners. A LO is defined in the LOM specification as “any entity, digital or non-digital, that may be used for learning: education or training” (LOM 2001). The LOM basic schema consists of nine categories and simply of two types/classes: the LOM resource and the LOM type, linked by LOM attributes (LOM data elements). In the model layer we have only the LO itself, the attributes describing the LO and the datatypes for those attributes. The descriptions of LOM are context-independent and static classifications. This is not appropriate for many instructional aspects: To characterize “collaborative learning” the type resp. the vocabulary “collaborative” can hardly be added to a single category, as “collaborative learning” is an instructional principle which affects and shifts the entire environment: the role of teacher and learner (Intended End User Role (LOM 5.5)), activities, interactivity type (LOM 5.1), Typical Learning Time (LOM 5.9), purpose, organizational framework, and many more. The current LOM model does neither provide concepts for modelling instructional models, instructional principles, nor to specify epistemological approaches.

Basic Instructional Framework

Pedagogical Dimensions – Abstraction Layers: We start by defining what we consider as pedagogical dimensions in this context. We choose a top-down-model in which pedagogical dimensions are embedded in different layers of abstraction - according to educational and cognitive sciences. In this model, LOM only addresses the bottom layer which is the most basic. 4th (highest) layer of abstraction: epistemology, paradigm: The highest level of abstraction addresses (whether implicitly or explicitly) broad orientation concerning epistemology resp. theory of cognition. 3rd layer of abstraction: (instructional) principles: Merrill refers to this layer as “set of underlying principles”. In literature as well as in practice we often find fixed terms comprising some well-agreed principles: Problem Based Learning (PBL); Case Based Learning e.g. 2nd layer of abstraction: instructional models, learning theories as well as communication theories and sets of strategies. Models often
structure and organize learning processes in several phases. *1st (basic) layer of abstraction: content, practices, activities,* sets of activities and scenarios. Curriculum programs assembling content are located at this layer. This layer tells which resources are actually used. The current LOM Metadata Schema only addresses this layer.

The top-down model presented in this paper is derived from German tradition of education. But there is obviously an urgent need for implementing a model in LOM that reflects both, American as well as European thought, and hopefully also other tradition in the field of instructional design. Analogies between these different traditions can be stated: Merrill’s approach of abstraction layers in instructional design (Merrill 2001) seems to be comparable to our perspective which is presented by German authors (Kösel 1993; Klafki 1993). A decision made on a higher layer of abstraction shifts the entire setting at the level of the basic layer: the ‘Typical Learning Time’ spend with one and the same LO may be different in a PBL scenario from an expository scenario e.g.. In order to solve the need for dynamic classification, we suggest to include the concept of roles in the meta-model.

**Instructional Roles – Instructional Aptitude:** Using LOM metadata we cannot specify the instructional aptitude of a LO. Is a LO suitable to be used in a scenario of collaborative learning or in a scenario enabling problem solving? **Learning Sequences – Learning Processes:** In separating content from structure, LOs are decontextualized. In our meta-model, LOs are integrated into different learning cycles supporting processes which are derived from different instructional models. In the role-concept of our meta-model learning theories and instructional models represent context. Merrill stresses the importance of phases in learning cycles (Merrill 2001). One and the same LO (types) may fill different instructional roles within learning processes set up by different learning theories. Our concept of roles stringently and clearly distinguishes the natural types of LOs (media type, tools e.g.) from their instructional role/purpose (Guarino 1992; Steimann 2000). The top-down model can be mapped to the concept of types (class) and roles (figure 1).

**Roles for Modelling**

There is a wide choice and diversity of definitions of the role concept in literature (in semantics e.g.). The concept of Roles in Modelling has been elaborated in (Steimann 2000a). Role expectations include both actions and qualities. Steimann distinguishes definition of characteristics from the player itself. (...) “a role is a kind of protocol specification specifying behaviour and characteristics, but not the role player itself” (Steimann 2000b). As opposed to natural types or classes, roles have strong dynamic aspects. Types/classes, which are the fundamental concepts in the object oriented modelling are inherently static: an instance of a class once and forever belongs to that class – it cannot change it without loosing its identity. A LO may fill different instructional roles. Learning Models are used as context of roles and determine relationships between entities.

![Meta-Model](image)

**Figure 1:** The extended LOM Meta-Model (The model distinguishes roles from types/classes)

The instructional role is compatible with the idea of the role concept: a type must have certain characterising predicates (Guarino 1994), qualities, attribute, or requirements in order to be able to fill a certain role. Characterising predicates, attributes and requirements are matchable with the concept of instructional aptitude. We suggest to name instructional aptitudes ‘instructional qualities’. The important advantage of the approach of instructional roles is its ability to deal with dynamic modelling and instantiation, in contrast to a standard class-oriented approach which is suitable for the static attributes currently included in LOM.

Dual Coding Theory and Computer Education: Some Media Experiments to Examine the Effects of Different Media on Learning

James L. Alty
IMPACT Research Group
Department of Computer Science, Loughborough University
Loughborough, Leicestershire, UK
j.lalty@lboro.ac.uk

Abstract: Dual Coding Theory has quite specific predictions about how information in different media is stored, manipulated and recalled. Different combinations of media are expected to have significant effects upon the recall and retention of information. This obviously may have important consequences in the design of computer-based programmes. The paper describes an experimental approach which has been developed using the Statistical domain in which the presentation media have been varied (Text only, Text and Diagrams and Diagrams with Voice-over). The results are compared with Dual Coding theory predictions and the effects of Student Learning Style explored.

1. An Early Attempt at Using the Web to Communicate Statistics Knowledge

Our interest in this work arose out of a desire to measure the effectiveness of Distance Learning compared with Face-to-face presentations. An opportunity arose in a second year HCI module which included two lectures on the use of the Null Hypothesis and Statistical Inference in HCI evaluation. We decided to divide the class into two groups, one of which would be taught face-to-face and the others over the Web. Presentation was mainly textual but some animations created using Visual Basic were also included. Students were first given a test to ascertain their knowledge of the material to be presented. There were some students with detailed knowledge, but most knew little about the domain. Throughout both presentations, questions were asked to enable students to check if they had understood the material. There were some students with detailed knowledge, but most knew little about the domain. Throughout both presentations, questions were asked to enable students to check if they had understood the material. The Face-to-face class was taught the material on the last day of term, and the Distance Learners were given access to the material once they arrived home in the vacation. Access was protected by password and, because the student homes were widely dispersed it is unlikely that any of the "lecture" students could gain access to the material. On their return to the University in the next semester, the students were tested for knowledge of the material through a series of questions. We marked the test with a simple scoring system – one point for a correct answer.

The results, as one might expect, were inconclusive. Overall, the performance of subjects on the post-test was similar for both groups. It was interesting that the Distance Learners did no worse overall that the Face-to-face Learners, though a number of them did report that they found working at home, alone, not very motivating. Scores varied widely (from 13 to 60). It was clear that some students in both groups had not taken the exercise seriously. It was also clear that previous knowledge had an effect (though students who professed previous knowledge did not always do well). Previous Mathematics expertise also had a positive effect on the score as might be expected. We had asked the Distance Learners to keep a log of their access to the system. Most did this and total access times reported varied from 1 hour to 6 hours. Some students also made comments on the way in which the material was presented. The material was heavily text-based and most comments suggested that more "interesting" media should have been used (whatever that meant).

Although this was only an exercise partly to illustrate to the students the problems involved in such experimentation, it did raise some major design issues for any future experiment:

1. By how far do different media affect the learning process?
2. At what level should the learning material for the experiment be pitched and how extensive should it be?
3. How can the students be motivated so that they make a serious attempt at learning?
4. How is the amount of material learned measured? Clearly correct answers to questions do give an indication, but how should the questions be phrased?
5. How is previous knowledge allowed for? Are marks only given for improvements in knowledge transfer? Does someone who knows it all before get zero!
2. Effect of Different Media on Learning and Performance

2.1 Some Process Control Results
We have previously studied the effects of using different media on the performance of operators carrying out a laboratory task. The task chosen was that of Crossman's Water Bath [Crossman & Cooke, 1974]. The task is closely related to the process domain [Sanderson et al., 1989].

There was a marked difference in performance across media. For example, the performance results differed when using Text and Graphics. At low task complexity the performance was very similar, but as complexity increased the differences start to show. In the more complex tasks the results are significant (p<0.03) with Graphical interfaces giving the best performance. After each sequence of tests, the understanding of subjects was tested with a questionnaire. The comprehension results showed significant differences in the performance between the use of Verbal and Spatial Coding in the interface.

Interestingly, spatial coding improved comprehension of the two least understood variables and this was a significant result (p<0.01). There is not space to report all the findings but the other variables showed similar trends [Alty, 1999].

Thus the choice of medium used does seem to have an effect on comprehension and this could be important in learning situations.

2.2 Dual Coding Theory
Dual Coding Theory (Paivio, 1986) assumes an orthogonal relationship between symbolic systems and sensory motor systems. The theory suggests that there are clear distinctions between the internal representations of Symbolic and Sensory-motor events. The stored versions of visual, verbal, and haptic events retain the modalities of these events. For example, in the visual modality there are printed words and images. In the auditory modality there are spoken words and sound events. Lion can be stored as an image of a lion, the word "lion", or both but within distinct systems. Of major importance is the verbal/nonverbal distinction. The verbal and non-verbal processing systems are assumed to be functionally independent though there are cross linkages between the two. If the Dual Coding theory is relevant then the recall of material will be affected by the way it is presented.

3. Choice of Learning Domain and Subject Motivation

Many experiments that have examined the effects of different media on learning have been constructed over relatively simple subject domains. The material being communicated to learners is often limited in scope and usually not complex in nature. There are, of course, good reasons for this. A complex domain necessarily requires a specialised user base, and an extensive set of learning material will impose serious time requirements on the subjects taking part. Yet it is important to really challenge subjects both with domain complexity and the extent of the material in order to obtain results which will scale-up for real situations.

One possible solution to this problem is to choose a domain that is acknowledged to be inherently difficult, is difficult to teach, and yet for many people, constitutes a most desirable skill to attain. Within a University context (the population from we from which we are most likely to draw subjects) there was an obvious candidate - Statistics.

Most Masters and PhD. students require statistical knowledge for analysing their experiments, and yet it is a subject most feared by many of them. Thus the Statistical Domain fulfils our requirements of being complex, of being not easy to teach, and yet would be regarded by subjects as a required and desirable skill. There should therefore be a strong motivation to take such a course and to take it seriously. Furthermore, at Loughborough University, we have a Masters course on Multimedia Interface Design, and an important aspect of the course is the design and evaluation of HCI experiments using Statistics. The material is typically taught in four one-hour lectures on the course and covers basic information about the Null Hypothesis, the Binomial Distribution, the Sign Test, the Wilcoxon Ranking Non-parametric Test and Normal distributions and their use. We therefore decided to develop Web-based material to teach the subject matter on the course and to additionally make the exercise an example of HCI experimentation and its evaluation.
We constructed four separate computer-based modules in FLASH to teach this basic statistical knowledge:

1. The Null Hypothesis and the relevance of Statistics
2. The Binomial Distribution
3. Non-parametric distributions - i.e. Ranking (Wilcoxon)
4. The Normal Distribution and the Central Limit Theorem

The presentations were constructed using three different media combinations of voice, text and diagrams/pictures. The material and timing was identical in each presentation. In other words, the text and the voice-over content were identical. Each of these media could be disabled so that a number of different presentation formats was possible. We actually used:

1. Text only
2. Text + Diagrams
3. Voice + Diagrams

These formats were preserved over a complete module presentation session.

4. Proposed Experimental Approach

Each developed presentation had an elapse time of about 10-15 minutes and each was presented in a serial non-interactive fashion. We planned to place subjects in a room and present the material on a screen using a computer projector. At the commencement of the first session all subjects were to be given a short questionnaire to determine their previous knowledge of the subject and would be told to write nothing down during the experiment, but that at the conclusion of the experiment they would be required to answer a series of questions on the material. If students were subjects, they would be assured that the results did not form any part of the evaluation process for their module.

The subjects would be tested for immediate recall of the material presented at the conclusion of the presentation. The post experimental test would consist of a series of questions about the presented material. In order to allow for the effect of previous knowledge, subjects would be able to indicate alongside their answer whether they already knew the answer before the session, whether the session had reminded them of the answer, or whether the material in the question was completely new to them.

5. The Construction of the Material

Because all the three different media presentations had to be based upon identical material, the construction of the different sessions was an interesting exercise in itself. When constructing the Voice-over + Diagrams presentation we had to be mindful of the fact that the Voice-over (as text) had also to work when presented as a Text-only session. This exercise in itself provides useful insights into the nature of multimedia presentations, how media are implicitly allocated for communicating particular types of material and the limitations some media have for communicating particular types of material. For example, communicating the idea that the results of an experiment might be caused by a set of independent random events is quite straightforward in text, but is not easy to do in a diagram. On the other hand some material (describing the shape of a normal distribution) is easy with a diagram but laborious using text. The Null Hypothesis concept is relatively straightforward to communicate using text but more difficult using a diagram. All the material was constructed in FLASH and each module was divided into a number of FLASH scenes. The scenes were transparent to the subjects, but we used this approach so that later the material could be adapted so that it could be presented in a more parallel, interactive manner at a future date.

6. An Initial Experiment

The first module was actually constructed in Australia whilst the author was a Visiting Research Fellow at Melbourne University Department of Information Systems. Towards the end of the Fellowship the author gave a commercial course on Multimedia Interface Design to a class of about 50 commercial, industrial and academic participants, which lasted two days. It was decided that this would be a good opportunity to run a pilot study of the first module during the course to give the participants an insight into evaluation techniques and to demonstrate the effects of different media on learning. From the point of view of the experiment, it would...
provide an exercise in creating the material, a test of the suitability of the material and provide experience in setting the post-experiment test. The participants (most of whom in the pre-test claimed not to have significant knowledge in the Statistics area) were divided into three groups and presented with the three different presentation styles — Text-only, Text + Diagrams and Voice-over + Diagrams.

All presentations were given in separate room areas using a computer projector. At the end of the test all subjects answered the same test to check recall of material. No learning style classification of users was attempted in this pilot run. The test administered at the conclusion of the experiment consisted of a series of questions, some of which were multiple-choice questions.

The results are shown in (Fig 1). The three vertical columns refer to whether the subject had met the domain or concepts before (A: Knew it, B: Previously learned and forgotten, but reminded, C: Did not know it). One can clearly see the effect of previous knowledge. The marks decrease as subject knowledge decreases. This experiment was only carried out as a pilot to guide future experimental design (for example, we did not expect to carry out any statistical analysis on the result) the results seemed initially to contradict Dual Coding Theory predictions. For example, the Text Only group (A) had a tendency to do better than the Voice-over-Diagrams group (B), whereas we might have expected the results to be in the opposite direction. However, a replay of the experimental material discovered an error. We had met with some trouble in starting the three presentations and, in the confusion, had actually presented Voice-Over+Text (not Voice Over+Diagrams) to Group (B). Thus in retrospect it was not surprising that the Group (B) performed badly. Previous experiments have shown that the redundancy of Text and Voice-over can worsen performance. Other interesting features were noted. Subjects who professed to know the material often still made recall errors. Finally we had great difficulty in analyzing the questionnaires in giving marks for recall and realized that the questions needed to be more carefully designed and related more carefully to the material.

7. The First Student Class Experiment

We reorganized the material so that each scene had clear learning objectives and the resulting questions were derived from these objectives. Some questions were carefully chosen such that even previous knowledge in itself would not enable a student to answer it. We also decided to test the students Learning Style using the Felder and Soloman Test (Felder 1993). The test identifies preferences on the axes Active/Reflective, Sensing/Intuitive, Visual/Verbal and Sequential/Global.

We asked students on a first year HCI course to take the learning style test. The spread of learning styles indicated that there were similar sized groups of Sensing Learners and Intuitive Learners in the class, and the rest of the students had Learning Styles balanced between the two. The class was then divided into three groups each group having an equal number of Sensing Learners, Intuitive Learners and Balanced subjects. A further regrouping improved the gender balance without disturbing the Learning Style balance.

The first module (Null Hypothesis) was then presented to the three groups of students — Text-only, Text and Diagrams, and Diagrams with Voice over. The results of this exercise are reported elsewhere in this conference (Beacham, Elliott, Alty and Al Sharrah, 2002). The media combination used was significant with respect to recalled material and it was shown that Learning style played an important part in the accuracy of recall.
8. The Extended Student Class Experiment

As a result of the success of the first experiment we completed all four modules and tested them on the students attending a postgraduate Multimedia Interface Design course (59 students, though all did not take part in all sessions). The students answered a questionnaire to determine their learning style. The test administered was again that of Felder and Soloman. They were then again divided into three groups (A, B and C) according to their learning style SENSING / INTUITIVE / BALANCED.

As far as possible, each group was balanced for gender and learning styles. Groups were given the four modules (in the different presentation formats) as detailed below in (Tab. 1).

Table 1: Groups and Presentation Formats

Since learning about Statistics was part of the course as well as the experiment, we did not want to disadvantage any students who might do less well on a particular presentation technique. We also did not want succeeding modules to be affected by any lack of knowledge gained in previous modules (though generally this was not a problem because most of the material was quite different). All students were therefore given a normal lecture on the material of a module after the presentation. They were able to interact and ask questions to ensure they fully understood the material. Any students who did not complete all sessions were removed from the sample. This left 37 students.

![Mean learning scores](image)

Figure 2: Preliminary Experimental Results

The results for the different media can be seen in (Fig. 2). In all cases the predictions of Dual Coding theory are borne out.

Our sample included some dyslexic learners. Although the sample was too small to be significant (6 subjects), the results did suggest that such learners might react differently see (Fig. 3), and this looks like an interesting area for more experimentation. The dyslexic subjects do not seem to follow the predictions of Dual Coding Theory (or at least there seems to be more complex interactions taking place). The results also indicated that the material based upon real world objects were recalled more accurately than more abstract visual material.

Certain learning styles were influenced more (or less) by different media (Fig. 4). For example, Intuitive Learners tended to out-perform Sensing Learners in all presentations, although in certain experiments, Sensing Learners using Voice/Diagrams outperformed Intuitive Learners using Text-only.
Acknowledgements

The author would like to acknowledge receipt of a research grant from the European ESPRIT programme for the PROMISE project (2397) and a grant from the German Government for the work on Dual coding. He would also like to thank Dr Nigel Beacham and Mr. Ahmed Al-Sharrah for assistance with the development of the learning materials and some analysis of the results.

Using Critical Components of Communicative to Measure the Distance Learning Experience

Distance delivery of educational material and adult-learning are not new concepts. From Paul’s letters to the Corinthians, to books from printing presses, to the mass media approach of film, radio, TV, and today the Internet, distance education has a long tradition of making use of available communication technology to store, transport, and disseminate information. But the storage, transportation, and dissemination of information do not constitute higher-level learning according to Bloom’s Taxonomy. Whether engaged in formal or informal higher-level learning, humans incorporate new information into their prior experience base (Mezirow, 1991). Humans ascribe value and meaning to their experiences and operationalize their knowledge according to their interactions with others (Mead, 1917).

Limited interaction, student to faculty and student to student, has always been one of the rationale for distance education’s struggle to gain equal prestige with traditional classroom settings. Major universities administer distance education programs as part of their extension services. Experienced educators perceive face-to-face communication as an essential part of the learning process. However, the advent of multimedia, hypermedia, and telecommunications for educational purposes has created a new opportunity to overcome not only the geographic barriers which have separated DE students in the past, but to provide all students the learning advantages of interactive communication. The ever-growing ability of computing and telecommunications to support interactive learning allows educators new opportunities to construct communities of learners to assist students in higher-level learning (Palloff & Pratt, 1999).

As the twenty-first century begins traditional educational institutions face several challenges:
- Mounting economic pressure (Increasing costs & reduced funding)
- The need to produce college graduates with the ability to function well in a knowledge society (Palloff & Pratt, 1999).
- Enrollment in post-secondary institutions is expected to reach 17.5 million by 2010, (U. S. Department of Education, 1996).
- As few as 1 in 4 college students fit the description of the traditional full time student, (Twigg, 1994).

Statement of the Problem

These non-traditional and part-time students are turning with increasing frequency to distance delivery to address their educational needs (Palloff & Pratt, 1999). Educational institutions are turning more frequently to the use of the Internet to deliver courses to nontraditional students, (Palloff & Pratt, 1999). The advent of the personal computer and access to the Internet has increased the opportunity for universities to offer on-line courses to DE students. The University of South Dakota began using a PC delivery platform in 1997. Within five years the number of courses archived in the system had grown to 338 courses. While researchers have examined the design and implementation aspects of on-line instruction, few studies have documented the experience from an online student's perspective, (Turkle, 1995).

The purpose of this study is to examine the relationship between graduate student satisfaction with the on-line learning experience and four criteria. The four criteria were established by Junger Habermas in his work, “The Theory of Communicative Action”, 1984. This study will attempt to ascertain by what degree graduate student satisfaction with the on-line learning experience is related to the interactive communication facilitated by multi-media and computer mediated learning situations.

Habermas states that all human communication is judged by the receiver using four critical components of interactive communication; coherence, relevance, accuracy, and honesty. Each message received is critiqued according to the receiver’s ability to understand the message, the perceived usefulness of the information transferred, the receiver’s perception of the correctness of the information, and the receiver’s perceptions of the motives of the sender. The student’s perceptions are key to developing understanding and trust for the other members of the group. Through interactive communication the group modified and re-enforced understanding and incorporation of information.

Significance of the Study

Many are the conditions, which must be fulfilled if the Great Society is to become a Great Community.... The highest and most difficult kind of inquiry and a subtle, delicate, vivid and responsive art of communication must take possession of the physical machinery of transmission and circulation and breathe life into it. When the machine age has thus perfected its machinery, it will be a means of life and not its despotic master.

John Dewey (1938, p. 38)
Dewey's choice of words reflects the pessimistic view of the human/machine relationship of many during the Industrial Age. And his words are nearly prophetic as to the focus and accomplishments of the Information Age. The Industrial Age was defined by rules and calculations, while the Information Age is defined by communication and collaboration. "Today, the lessons of computing have little to do with calculation and rules; instead they concern simulation, navigation, and interaction", (Turkle, 1995, p. 19).

This study explores the communication phenomenon of the internet learning experience from the graduate student’s perspective and seeks to increase educator awareness of the theories guiding interactive communication. While there is a need for quantitative measurements to insure system functionality and course content, there is an equal need to make qualitative measurements of the DE communication experience. Addressing the communication experience of the graduate and professional level students is essential for DE's evolving mission and desire to maximize student learning opportunities.

The general purpose of this study is to analyze the relationships between the critical components of interactive communication and graduate student perceptions of the on-line learning experience. Specifically this study will ask graduate students taking DE courses through South Dakota's DDN and computer-mediated communication network. Students will be asked questioned concerning administrative, technical, and interactive communication issues. Questions dealing with interactive communication issues will be constructed and critiqued according to the critical components of interactive communication theorized in “Communicative Action Theory”, Hubermas (1984).

**Population and Sample Selection**

The population for this study was limited to graduate students studying at three public universities located in South Dakota. Participants in the study have all recently completed a graduate level course delivered primarily by remote means or containing remote components through South Dakota's DDN and computer-mediated communication network.

**Instrumentation**

A narrative approach will be utilized to achieve the purposes of this study. A select group of graduate students participating in CMC distance delivery courses will be ask to share their experiences with and observation of the CMC classroom. A narrative approach to research allows people to voice their values and preferences, increasing our collective knowledge of the human experience (Bakan, 1996). The scale for this study will have six components: frequency, honesty, relevance, openness, affiliation, and student satisfaction. The student satisfaction component will draw from questions (p. 158) and issues concerning online learning communities posed by Pratt and Palloff (1999). Issues to be explored will include: frequency and mode of communication, student perceptions of the honesty, relevance, and openness of the online classroom environment, and student perception of the effectiveness of CMC communication.

This study will primarily use interviews to obtain data. Interviews will be conducted in person, by phone, or over the Internet. Participants will be asked to disclose basic demographic information.

Abstract: In close collaboration with the staff of the Pew Internet & American Life Project (www.pewinternet.org), the American Institutes for Research (AIR) is conducting a qualitative study on the impact of the Internet on schooling and education from the perspective of middle and high school students. Primarily through the conduct of multiple in-person focus groups that are being held across the country, we focus on the behaviors, beliefs, and attitudes of middle and high school students about access to and use of the Internet for schooling, including (intended and unintended) outcomes of those uses. Among the questions we are most interested in pursuing: Is the Internet helping students learn and why? What activities do students consider and pursue as “educational” on the Internet? What are the other outcomes (intended and unintended) of educational Internet use (e.g., social interaction, interest and motivation, writing skills, post-secondary goals, etc.)? Based on this knowledge, how could the Internet be better used by schools? Other data collection strategies include the surveying of focus group participants (to better describe our sample), as well as the online solicitation of stories about the use of the Internet for education directly from students.

Introduction

“Overall, I really think that the Internet has a great impact on how much I learn at school and without it I don’t think that I would have the opportunities to learn as much as I do.”
— Midwestern female HS student, online storyteller

Given the relatively high levels of Internet access in schools and homes, it stands to reason that youth are increasingly online. In fact, this is the case. By the age of 10, youth are more likely to use the Internet than anyone at any age beyond 25. As of September 2001, about two-thirds of 10 to 13 year olds—and more than three-quarters of 14 to 17 year olds—reported using the Internet at any location. We know, then, that youth are online more and more. However, we know less about what they do online—especially for school.

To date, most research on the use of the Internet in schools and for school—as distinguished from research on the use of computers and other technologies—has focused on access. This has consisted of measuring the extent of connectedness to the Internet and supports for Internet use in schools (i.e., the amount and adequacy of teacher professional development and technical support). A few large-scale surveys, most now several years old, provide some modest insights into the extent and types of Internet use in schools, though typically from teachers’ or school technology coordinators’ perspectives. Unfortunately, the current knowledge base is exceedingly limited in its ability to describe the rich details of educational student Internet use and outcomes, particularly when this use is occurring outside of schools and classrooms.

The Study

To provide insight into the rapidly evolving influence of the Internet on schooling, the American Institutes for Research was commissioned by the Pew Internet & American Life Project to conduct a study to describe the rich
and varied ways that middle and high school students use the Internet for school and learning, their attitudes toward the Internet, and what they would like from their education. Data for this study were collected primarily through three mechanisms:

- The conduct of 12 focus groups of a total of 136 diverse middle and high school students drawn from across the country who characterized themselves as heavy Internet users, coupled with 2 focus groups of light Internet users (comprised of one middle and one high school group);
- The administration of questionnaires to each focus group participant in order to help characterize their school-related Internet use both in-and out-of-school; and,
- The online solicitation of student-written stories detailing how they use the Internet for school. Nearly 200 middle and high school students from across the country wrote and submitted their stories to AIR through the study's Website.

Findings

Preliminary findings show that students who use the Internet a great deal use it for communication, entertainment, and learning purposes—including gathering and synthesizing information for school. There seems to be a disconnect, however, with the high Internet skill and knowledge that these students have, and the access and uses that that schools and teachers provide for them. A final report with these and numerous other findings and implications will be available at http://www.pewinternet.org/reports in the summer of 2002.

THE SCULPTUREQUEST MICROWORLD PROTOTYPE

Jacqueline Austin
jaustin@gmu.edu
Nada Dabbagh, Ph.D.
ndabbagh@gmu.edu
Graduate School of Education, George Mason University, United States

Abstract: This presentation demonstrates the SculptureQuest Microworld Prototype, designed to allow sculpture students to implement rapid prototyping in their production process. The Microworld's purpose is to promote metacognitive learning outcomes and enhance domain-specific skills and knowledge related to the art of sculpture. The Microworld's programmed environment delivers customizable, constructivist strategies that drive the effective use of technology within a classroom context. Teachers and students are encouraged to add, delete, or reprogram features as necessary to adapt the tool to their particular needs.

Introduction

The SculptureQuest Microworld (SQMW) is a learning environment in which the student uses interface and display capabilities of a contemporary 3D computer modeling GUI to perform functions which rapidly prototype sculptural pieces. In addition, analytical features output the physical parameters of prototyped sculptures and installations as if actually built. This allows recognition of the strengths and weaknesses, or logical outcomes, of decision points encountered throughout the creative process of sculpture. SQMW is meant for use in a classroom setting with emphasis on examining relationships between the artist's mental models and artistic processes.

In a non-traditional environment, where knowledge is assumed to be constructed and experiential, learning objectives must reside within the learner and her cognitive/metacognitive abilities (Lin, 2001). One major outcome of employing SQMW in a pedagogical setting is the integration of metacognitive and domain-specific activities, scaffolding student self-knowledge and domain knowledge simultaneously. The output data directly relates actual material outcomes with specific design decisions and promotes transfer of knowledge to the larger physical world.

The Microworld Model

The use of the microworld model to represent the technology piece of this course is a good fit. Strohecker (2000) identifies microworlds as inquiry-based learning environments, inherently constructivist in nature, simple in principle but rich in possibilities for playful, thoughtful activity. Land and Hannafin (1996) add that students rely on the open-ended nature of microworlds to support experiences necessary to identify, question, and test the limits of their intuitive beliefs.

Battista (1998) provides the most concise criteria for what constitutes a microworld by stating that this environment should: 1. Support problem-centered inquiry 2. Be based on research of students’ domain-specific learning 3. Cultivate mental models of abstract ideas and 4. Induce reflection and abstraction. SQMW supports each of these criteria using programmable features including the Diary tool, the Self Assess tool, the Playback tool and the Video Assistant.

The Course

College students who possess familiarity with 3D computer drawing programs comprise the target audience for this course. It is likely that these students will initially possess only a beginner's awareness of metacognitive techniques. Despite the fact that this Microworld exists as a computer environment, its real context is the social milieu of the classroom. Students and teacher must together navigate techniques for developing metacognition, using sculpture as a focus. It is necessary for all to meet in the spirit of collaboration to develop a mutually agreed upon approach for the semester. It is at this time that SculptureQuest is programmed for specific needs that the class has developed. Next, all parties agree to follow through with the agenda, using the Microworld features to record and sequence events, observations and insights that arise.
How the Microworld Works

There are two worlds found in SQMW: Explore and Prototype. Explore provides 2D and 3D objects as building blocks that can be assembled into complicated three-dimensional arrangements that may be assigned material characteristics. This is the environment most attractive to the novice learner who is examining basic shape relationships, physical/structural properties and sculptural concepts. Constructions may be exported to "Prototype" for further study. The Video Assistant (V/A), Playback and Diary tools are also available in Explore.

Prototype provides a more demanding-for-mastery set of tools and an environment in which construction and analysis take place. This area is the primary strength of the Microworld. All material and structural analysis takes place here and a sculpture may be continuously modified through design iterations. It is within the Prototype environment that the metacognitive activities incorporated in the Video Assistant (V/A), the Diary, the Playback, and the Self-Assess tools (combined with the social environment of the classroom) come into full play.

The Microworld Tools

The Tool designs are based on findings from cognitive research. The Diary Tool has its roots in Lesh’s Construct Documentation Principle (2001) that requires activities to contribute to both learning and documentation of learning, thereby fostering self-reflection. Lesh claims that thinking about thinking does not come easily without scaffolding. His work recommends thought-revealing activities that encourage students to externalize their thought processes in order to facilitate reflection (Lesh, et al. 2001).

The goal of the Self Assess Tool is to stimulate self-explanation through prompts that serve to guide student attention to conflicting thoughts and build coherent understanding of the domain tasks. Findings by Chi, et al (1994) show prompts lead to extensive inference.

Lin and Lehman (1999) also use prompts in a computer-simulation developed to aid students in designing biology experiments. Monitoring how and why certain decisions were made is effective because students are able to pin down specifically where and what they did not understand. Instead of self-assessing at a general level as expressed in the statements "I don’t understand" or "I am confused", the students are able to explain specifically what they did not understand and where the difficulty occurred (Lin and Lehman, 1999).

Conclusions

The SculptureQuest Microworld has been integrated into a course on sculpture studio practice to demonstrate that technology may effectively support Lin’s findings that the best approach for optimal learning outcomes is to practice metacognition within a domain-specific context (Lin, 2001). Hence, while the design of the computer piece is significant, it is the design of the course in which it is used that will determine the effectiveness of SQMW for cognitive and metacognitive learning outcomes.

Abstract: An increasing number of nations connect their schools on the Internet as an acknowledgment to its extreme importance in the education area. Our study specifies the perils that arise from its use when the users are minors and evaluates the technologies that are currently available to address the filtering issues. The thoughts presented in this paper outline our proposed solution for the Greek School Network. By no means the thoughts that are presented here, apply for adults or people who pay to establish access to the Internet.

INTRODUCTION

As the number of computers in schools and the number of children accessing the Internet from the classroom have grown exponentially over the past few years, so too have the challenges facing educators trying to ensure that children have a positive experience when they go online. The educational community cannot ignore the problem, as it will be like it accepts the use of the school network resources for purposes irrelevant to every possible educational goal.

A related debate rages over what percentage of Web sites would truly be considered objectionable. Some advocates argue that sites that would be considered harmful to minors represent only a very small proportion of the Web. What is of greater concern, they say, is that perfectly benign and possibly very useful information could be blocked when software is used to screen inappropriate material. The actual extent to which adult-oriented materials are available on the Internet is irrelevant according to those who support content controls. They believe that any amount of inappropriate content is too much, when children are concerned. Some experts argue that the Web is expanding so fast that it is virtually impossible to track every site that could be
objectionable. The flip side of that argument is that it is better to minimize access to objectionable content as best we can, even if the occasional site slips through the cracks.

Although pornography on the Internet has captured the greatest attention on the part of policy-makers, it is not the only area of potential concern for parents and educators. Many adults are concerned about Web sites that are created by hate groups or devoted to topics such as bomb making and weaponry, gambling or alcohol and smoking. The World Wide Web, however, is not the only source of concern. Children can receive email messages with pornographic file attachments. Of special concern, too, are Internet chat rooms and so-called Instant Messaging, where children can communicate online in real-time with adult strangers who may not have their best interests at heart.

A wealth of information is available on the Internet. White papers [4,5] are opposed to the use of censor ware programs (they call it) in the American libraries and schools, and there are some interesting links that are indicative of the ongoing debate [2,6,9,10].

The Internet truly is like a vast library including millions of readily available and indexed publications, containing content as diverse as human thought. Throughout the past decade, policy makers, industry advocates, parents and teachers have tried to address these concerns especially in the more technologically advanced areas of the earth. This decade may well be the decade of decisions in a much broader spectrum than ever before.

From our point of view it is an unarguable fact that Internet offers a vast mass of information, some of which is suitable for schools whilst some is not. Without meaning that we should implement extreme measures of censorship or suffocative limitations to the content we allow our users to access, we should be alert and monitor the things that happen while students are online. The problem with Internet content seems to have social, cultural, pedagogic and scientific viewpoints: Schools' trustworthiness is endangered if the school network is used (systematically or occasionally) for other purposes than those for which it was designed and implemented. The parents and the public believe that their children and students proportionately, should be protected from illegal, offensive and inappropriate content. Whilst some may argue that it is a means for censorship and nothing more, others believe it is the only way societies have to inform and protect the children from the potential danger the Internet poses.

Every country should establish its own policies to deal with it without raising public concern regarding human rights and individual's freedoms. This document will try to group all potential dangers the Internet can pose and some possible solutions to those dangers. For us the best solution is the one that combines the right guidance of the students from the educational authority, the informing of parents and the training of educators together with the technical solution. No solitary technical working-out can resolve such a problem and whichever policies put forth should take in mind all the above parameters.

Status in the other Countries

Each of the countries presented here, establishes its own policies and methods. However, their perception of the problem presents some surprisingly common characteristics. In our survey we browsed some interesting and concise pages regarding the pronounced decisions on the Internet content issue in Australia [12], Canada [7], United States of America [3] and the European Union [11].

Internet is being used in Australian schools with highly increasing rates, as a learning driving force in education. 43% of the children asked in Australia said that Internet improved their perception about school. The federal government of Australia responded to the issues posed by the entrance of Internet in the everyday and school life, with the Broadcasting Services Amend ment Act (1999). A hot line was created to allow people report what they think is illegal and express their worries about the content that can be accessed on the Internet. The industry plays important role by establishing policies for the improvement of the information exchange regarding the content of the web pages. In some cases schools store pages certified as 'safe quality pages' in their cache, ensuring by that way that their students have quick access to them. While these pages are available for the benefit of students reducing the bandwidth consumption, the costs for schools remain low because of the quicker access time achieved for stored sites. In Australia the decisions are made on the school level (in some states there is a trend for more obligatory policies decided on a higher level of authority). Education authorities stress the importance of accessing pages of high quality. Educators in national level do the evaluation of pages selected to meet certain specifications. Recent studies point out that almost 98% of public schools connected to the Internet have established Acceptable Use Policies. 74% of schools with AUP use software to block or filter pages of certain content, 64% uses rules of conduct and 28% uses an intranet in their effort to control access.
To date, Canadians have established a wide range of partnerships to deal with the issues of the Internet content. The strategy of Canada's Government is to make Canada the most connected country in the world. Illegal content — content that violates Canada’s laws — is of key concern to Canadians. Child pornography and hate propaganda are particularly troubling, because they pose the greatest and most immediate risk to the safety and well-being of Canadians. Enforcing the law in cyberspace, however, presents significant challenges, particularly in view of rapid technological change. For Canadians it is important to distinguish between Internet content that is illegal, and content that is offensive to some, but is not illegal. The control and management of offensive content, however, calls for different approaches, such as empowering users, educating consumers to make informed choices, and establishing responsible industry practices. The Canadian Charter of Rights and Freedoms guarantees all persons in Canada "freedom of thought, belief, opinion and expression, including freedom of the press and other media of communication". The federal government's approach is to involve a broad spectrum of Canadians in addressing the issues. Its priorities include supporting initiatives that educate and empower users, promoting effective industry self-regulation, strengthening the enforcement of laws in cyberspace, implementing hotlines and complaint reporting systems and fostering consultation between the public and private sectors, and their counterparts in other countries. A considerable number of important initiatives, studies and discussion have taken place or are in progress in Canada. In 1994, the Government of Canada established the private sector Information Highway Advisory Council (IHAC) to provide advice on the best way to develop Canada’s Information Highway. According to its recommendations the federal government should a. fine-tune existing laws to make them more applicable and enforceable in the changing world of global networks and b. encourage research and the development of technical tools that can protect users against offensive content on the Internet, and assist in law enforcement.

The United States of America Congress passed legislation requiring Internet blocking technology to block pornographic materials in all public schools and libraries funded through certain federal programs. The Children's Internet Protection Act – CIPA passed the senate and the congress on December 2000 as part of a big government budget for the year 2001. To date the issue of content control in the United States of America is in a critical point: while the congress decided the mandatory implementation of filtering in schools and libraries, parents, organizations and politicians are steadily opposed to the legislation passed. Influential organizations are hostile to it and government bills mandating filtering in schools and libraries face legal challenges on constitutional issues. Some libraries have already been sued for installing filtering software onto their computers. Parents, schools and libraries face difficulties to decide whether, and how, to filter Internet content [8]. Still nobody denies the fact that the World Wide Web is not content zoned, which means that kids can access anything on it very fast and very easily. As for the libraries, while school libraries have special characteristics, public libraries are intended for free willing inquiry and access control is a more complicated issue.

The European Union has published an Action Plan on promoting safer use of the Internet [4]. While it recognises the positive benefits of Internet (particularly in education) it states that the amount of harmful and illegal content carried over the Internet, while limited, could adversely affect the establishment of the necessary favourable environment for initiatives and undertakings to flourish. A safer environment should be provided by combating illegal use of the technical possibilities of the Internet, in particular for offences against children and trafficking in human beings or for the dissemination of racist and xenophobic ideas, ensuring that consumers make full use of the Internet. Europe should promote industry self-regulation and content-monitoring schemes, the development of filtering tools and rating systems by the industry and of course international cooperation. While any hot-line reporting mechanisms should support and promote measures taken by the Member States, duplication of work should be avoided. The responsibility for prosecuting and punishing those responsible for illegal content should remain with the national law-enforcement authorities.

Techniques and Solutions

The techniques that can be used to achieve content filtering are keyword blocking, negative and positive lists and content labeling and rating systems. Keyword blocking prohibits access to pages that contain the specified words (words can be tobacco, wine, drug, sex etc). Unless this is a ‘clever’ software (rarely this is the case) this technique cannot successfully address the modern issues. It can be easily bypassed as it has been reported that web developers add additional characters to the words they suspect that can be searched for. The use of negative and positive lists is easy from filters or browsers. The positive lists contain URLs and domains to which access is allowed to and negative lists contain the URLs that access is prohibited to. Use of white lists will be very
restricting regarding the amount of available pages on the net. Labeling and rating systems provide a way to categorize pages according to their content and provide that categorization to the user. That technique can proved to be inefficient if nobody offers to undertake the task of labeling. The main problem is the size of the Internet and the rate of its daily expansion (there is some indication that Internet growth today has gone from exponential to linear). Access control can be achieved using Commercial Software, Freeware Programs, Rating Systems or Hardware Solutions (all of them are mainly structured on the use of lists).

Many commercial filtering programs advertise that can block access to the harmful or improper pages on the Internet (in fact they claim they can do much more). There are programs that can be installed at the server side, some are for clients only, while other offer versions for home and for education. The problem with commercial software is that the companies usually do not reveal the pages they block access to [4]. This solution is not favorable for a school environment for one more reason: The filtering is done by a third and not by the government or an educational authority. This gives to the company that implements the filtering, access to sensitive data. The use of proxies has a policy problem: proxy servers keep log files. These files contain all the requests a proxy receives, causing complaints and worries regarding the people that gain access to that data and the processes that can be put in place to monitor individual users' behavior. Although it seems that today there is a some development under way on rating systems everyone should remember that this method might proved to be of little efficiency if there is not someone who will undertake the task of labeling and rating of sites in Internet in a continual basis. Hardware solutions appear to be more complete, with specialized systems of black box type. They are intended as big scale solutions for huge users' databases and lines of high capacity. They require minimal efforts to be installed, configured and operate while full support is offered from their company. Along with that comes the usually high cost to obtain such a system.

Policies

Currently in Greece there is no government decision regarding the policies mentioned here. The policies' part of our suggestions - it could also serve to initiate a public discussion regarding content filtering and content blocking in Greece - is:

1. Creation of Acceptable Use Policies for the Greek School Network to inform users for the purposes of the creation of the technological infrastructure of the school network and the actions or behaviors that are considered acceptable. Most such policies include: Description of the underlying philosophy and strategy implemented into the school network for the access to Internet, Report of the educational uses and advantages of Internet, List with the catalogue of the duties teachers and students have on the issues involved by the use of Internet, Description of what is considered acceptable and what not acceptable use of the school network and of the Internet, Reminder that the access to the school network and to the Internet is a privilege, Specification of the pages considered as 'improper', 'harmful', 'illegal', or 'void of educational content'.

2. A critical point is the responsible, with no exaggerations informing of the teachers. Without their sincere participation success will prove hard.

3. Control of the time and opportunities students will have access to the computers (when in lesson hour, they will be supervised from their teachers).

4. Control of installation of software on school computers. The common problems are license issues, installation of 'Trojan horse' programs (programs with malicious or harmful code), worms, etc.

5. Availability of educational material to constitute the positive counteroffer. The network itself is not the main objective: The main intension of schools is the use of all possible ways and new technologies for educational purposes, and therefore the use of the school network and equipment for specific cognitive purpose.

6. The age of students should be taken in consideration (ages from 6 to 11 are the most vulnerable).

7. Provision of the cachemaster's mail address for communication between him and the school community.

8. Extra security considerations and policies if the school provides email accounts for students and teachers (not true currently in Greece but visible in the very near future).

Architecture

The Greek School Network's topology is illustrated in the next figure.
The backbone network is the Greek Research and Technology Network (GRNET), which provides Internet Services to the Greek Academic and Research community. The distribution network is the part of the network that interconnects points of presence (nodes) with the backbone network. The topology has such design in order to preserve the operational cost in low levels, which is particularly critical in large geographical region networks. The proposed architecture is in favor of the use of a proxy-cache server for the school network because the proxy server on a network-especially when it is configured as transparent-is the ideal point for the implementation of control on the requested objects.

The extent of Squid's usage in educational networks all over the world and the level of acceptance it enjoys from the global networking community (especially researchers, scholars and educators), is obvious from the number of networks implemented on: the JANET network (a private, government funded network for education and research in England with 90 to 120 million hits per day), the Italian GARR network, the German DFN network, the Swiss network SWITCH, the Dutch network SURFnet and the USA academic network the NLANR. We are going to use Squidguard as the redirector of our choice because it is faster and opens less redirectors than its competitor programs.

**Implementation Issues**

Squid is free software, licensed under the terms of the GNU (General Public License). The most important resource for squid's performance is physical memory, so fast disks are important for high-volume caches. Some new options were added to squid's configuration file after its last release. All new parameters intend to improve the performance, the security or the flexibility of the program. Available options are selective logging and the use of time spaces, ip ranges or users ids in order to grant or deny access at certain hours of day, at certain ips or at certain users.

**Conclusions**

The rapidly evolving nature of the Internet virtually ensures that no filtering technology can be a hundred percent perfect. Certain kinds of network management products may provide basic information on how students and staff are using the network but the parental and school guidance will remain the basic factor to the solution of the problem.

If a school district employs monitoring or filtering, its Acceptable Use Policy should explain what it would be doing, and the procedures a student should follow if he or she encounters a site that would be considered inappropriate.

The practices are quite the same across the different nations. This happens because the filtering problem is relatively new and those who started first to deal with it lead the way. The content filtering issue we discuss herein has never caused a central debate either from parents for their kids or from school teachers or even from the government in Greece. We work on that issue because we believe that every country should be aware of the possible dangers and be as prepared as possible to deal with them. If we know and understand what happens in the rest of the world and in countries that have a lead over Greece in technological issues we will save ourselves time and trouble.

The biggest percentage of the pages on the net is written in English which is nowadays an international language. Therefore the most interesting sites and definitely those which get read from the biggest audience are
the same even for the countries whose language is other than English. That means that the problems are the same since their source is the same. This is why many countries seem to adopt the same strategies despite their natural differences.

A convenient solution for the most educational institutions has been the installation of filtering software on the proxy server. This is the ideal place to do filtering for a network because it is the one point through which all network communications pass. Filtering on a proxy server can have an impact on network performance because of the need to match a URL against what may be a long list of blocked sites. The use of a caching server can help speed access and reduce the bandwidth that would otherwise be needed.

Web server surveys have shown there were more than 27 million web servers in operation as of January 2001 [15]. One study estimated the Web to have approximately 800 million pages in February 1999 [13]. While the above results are not accurate for 2001, they are indicative of the order of magnitude of the sites on the Internet. If this is to change, obviously it won’t shrink. The lists every software uses to block access to sites will probably include controversial entries. As these lists cannot be human reviewed the common way to cope with problems that might arise is the creation of an environment which allow the modification of the lists and provide the required information to the users.

Even if we find the ideal solution and implement it in our school networks, no one can guarantee that this will be the ideal solution or even an appropriate one, in one or two years time. People with wide knowledge of the Internet and the emerging technologies should monitor the developments that take place and adjust their policies to the new era.

Implementation of content/access control doesn’t solve radically the problem of students using the school networks to gain access to objectionable or illegal material. There is a number of ways that can be used to exchange that material and email and ICQ are only the two most common programs to do that. While solutions for that issues do exist (there are programs that allow only the execution of authorized programs, while the rest are locked out), the governments and the school communities should decide if they wish to implement so hard constraints.

Future Work

Our future plans include the improvement of the current design and architecture to best fit the continually emerging technologies and to therefore address successfully the new problems that almost certainly will come up. The listing of the blocked sites (everybody could see it) and the ability to add or remove sites to the squidguard database (administrators only) through a web interface is a big priority already on discussion.

An investigation of collaborative problem solving using different communications modes in Distance Education

Abstract: This paper reports results of a mixed method, multiple case study of collaborative problem solving by distance education students. Four groups of students were assigned to solve a multifaceted task and write a comprehensive solution report using the following net-based technologies: synchronous audiographics, synchronous text chat, asynchronous voice conferencing and asynchronous text conferencing. Time on task logs and reflections on group process as well as final assignment marks are compared among the four groups.

Researchers: Terry Anderson, Ph.D. Athabasca Institute for Research on Open and Distance Learning
Liam Rourke, Ph.D. student, University of Alberta

Research Rationale: An increasingly large number of technologies can be used to support collaborative learning and teaching at a distance. Generally these technologies can be divided into those that support synchronous vs. asynchronous collaboration and those that support voice vs. text interaction. Instructors and course developers are forced to make decisions about which medium or which combination of media to use when assigning collaborative activities. There is little empirical work with actual students, in natural conditions, that informs this decision making process. This study will provide insights based upon analysis of a variety of triangulated data as a first step in developing guidelines and theory relevant to this decision making process.

A long history of media comparison studies has provided little evidence that any particular media has inherent education advantage over any other (Clark, 2000; Clark, 1994), however it is likely that particular media attributes are more or less congruent with particular learning activity and instructional designs (Kozma, 1994) and perhaps with different types of learners (Lara, Howell, Dominguez, & Navarro, 2001). Many of these media comparison studies have been conducted in laboratory settings and lack ecological validity and authenticity. This study uses groups of students who have some prior knowledge and relationship with each other (they are program students in a large Masters of Distance Education Program), the collaborative project is meaningful in that it relates directly to the course requirements, and is relevant to problems they face in their own workplaces and finally the study takes place in the context of a real distance education program. Finally, the type of collaborative problem solving and report generation is an activity very common to actual workplace tasks assigned to distributed teams in business and public sector employment.

Each of the technologies used is web based and commercially available at relatively low cost – at least as compared to the costs of face-to-face interaction.

Research Question: What is the efficacy and the participants’ perceptions of synchronous/asynchronous and text/oral modes of interaction in distributed teams engaged in collaborative problem solving and report generation?
Study Design:
The study is based on mixed method, multiple case study design using each of the four media groups as separate cases (Yin, 1994). Four to five students will be randomly assigned to each case. The technologies used will be:
1. Asynchronous text based conferencing - Bazar
2. Asynchronous voice based conferencing using - Wimba
3. Synchronous audio graphics – Tutor’s Edge
4. Synchronous chats – Chat using WebCT

The groups will work over a two-week period to research and produce a final report addressing the following problem.

The Board of SaveMore College has just developed a strategic plan calling for an increase of 50% in enrollment using distance education technologies. The Faculty Association has threatened to strike if this new policy has any adverse effect on Faculty work loads. The Vice President has asked your team to prepare a 8-10 page report for both the Board and the Association that alleviates the Faculty concerns and provides a set of Action Recommendations that allows implementation of the new strategic plan. The report should recommend a technology platform and discuss the effect on the college budget of your recommendations.

Subjects will be asked to refrain from using other technologies to support collaboration except private email (the extent of email used will be logged).

Data Collection and Analysis
The following data will be collected, analyzed and results triangulated:
- Time on task spent by each individual (aggregated to obtain group totals) group gathered from time logs of individual and group work.
- Data on perceptions of ease, understandability and confidence in the media (Steinfield et al., 1997) obtained from 3 Likert like scales included with the time logs.
- Perceptions of efficacy of process and output gathered from summary reflection memo’s from each participant and analyzed qualitatively for themes using constant comparative methodologies (Strauss and Corbin, 1990). A guide identifying issues to be addressed will be given to each participant and serve roughly the same function as a semi-structured interview guide.
- Final team mark awarded for each group
- Audio conference focus groups with each group conducted at the end of the experiment to develop collaborative understanding of process and gain understanding of divergent views of media effect on that process (McNamara, 1999).
- Thematic qualitative analysis of transcripts and logs derived from group interactions captured by the system software(s). Particular attention will be paid to
appearance and frequency of group process questions, communications breakdowns and other indicators of the quality of the mediated interaction. These data sources will be analyzed to calculate the efficacy of each system by determining objectively the mean time spent on the project by each team and dividing this by the final mark to get a measure of efficiency of each media in supporting the team and its work task.

**Results:** As the study will not be run until March 2002, results are not available at this time. It is likely that there will be little significant differences between the groups based on teacher assessment of final product, however the time on task and participants perceptions of learning curve, ease with which organizational tasks were supported, reports of communications breakdowns and related organizational issues and perceptions of efficacy of the four media types will be rich in insights for both researchers and practitioners.

Abstract
Ninety-eight technology-enhanced lessons are now available on-line. Teams of professors, K-6 teachers, and pre-service teachers in South Florida have worked together to write, refine, and field test lessons based on the ISTE and Sunshine State Standards. These tried and true technology lessons are complete with downloadable resources and assessment rubrics for each standard taught. Math, Science, Social Studies, General Methods, Curriculum and Reading/Language Arts lessons round out the subject areas addressed in the lessons. There are also specific lessons that address special needs populations including English as a Second Language and Exceptional Education students. The lessons have been field tested in classrooms with urban high-need students, limited English proficient students, and suburban students. An overview of the resources available will be presented with opportunities for interaction. Elementary Education Teacher Education Professors, Curriculum Developers, and K-6 Teachers can make use of these well developed, peer reviewed resources.

Contribution to the Field of Educational Technology

1. The research involved in the creation of these technology enhanced lesson plans reflects the cooperative effort of pre-service teachers, professors, and in-service teachers. Thus, the product is well balanced with a combination of sound research and field-based experiences.
2. The recent development of the ISTE standards has opened up a new area of curriculum development based on those standards. This research project provides materials that address the need for high quality field-tested and peer reviewed lessons based on the new standards.

3. The lessons developed reflect the up-to-date availability of resources in the college and K-6 classrooms.

4. The lessons are based on curriculum standards as well as ISTE standards.

5. Professors from several institutions of higher education have worked together to create the lessons.

Objectives and Outcomes:

1. This session will address the need for high quality technology enhanced lessons based on both State and National Standards by providing on-line resources to attendees.

2. This session will supply assessment instruments to evaluate the use of technology for all lessons that address the State and National Standards.

3. Technology enhanced lessons at the K-6 level will be shown for Math, Science, Social Studies, Reading/Language Arts, Curriculum, General Methods, ESE and ESOL.

Importance:

1. As professors in schools of education seek to integrate technology into their teacher education classes, they can use these resources to assist them.

2. As K-6 teachers seek to utilize technology in their classes, they will be able to find resources on the curriculum area of choice by using the search engine presented based on the Sunshine State Curriculum Standards.

Abstract: In this paper we propose adaptive hypermedia educational system using XML technologies such as XML, XSL, XSLT, and XLink. Adaptive systems are capable of altering the presentation of the content of the hypermedia on the basis of a dynamic understanding of the individual user. The user profile can be collected in a user model, while the knowledge about the domain can be represented in the form of a concept based domain model. So we have defined two different markup languages using XML. And for adaptivity of system, adaptive presentation of the data comes using XSL and adaptive navigation of link comes using XLink.

Introduction

With the rapid advances in WWW interactive technologies, the use of Internet-based distance learning tools is rapidly growing. Most of these products are nothing more than a network of static hypermedia pages. In fact the domain knowledge implicit in traditional educational hypermedia is well defined and carefully structured and provides an only learning path optimal for a generic average student [Ek1997]. Otherwise, a Web application, which is designed with a particular class of users in mind may not suit other users. Moreover, "static" hypermedia assume that the users can make sensible decisions about when to use navigation tools, about when to proceed in the learning process, about when they need an explanation, etc. [Bru1998]. This could be a problem for those users who access the hypermedia through the Internet and that can’t have a teacher at their disposal.

Adaptivity is the feature of hypertext and hypermedia that allows one to adapt the contents to the user needs[Ada2001]. Adaptive hypermedia systems modify the presentation of the domain knowledge according to the user profile. This mechanism permits to personalize the Hypermedia in terms of contents and of navigation tools for each user.

The focus of this paper is on the general architecture and the implementation issues of a adaptive educational hypermedia system. This system has been implemented by using the functionalities provided by XML(XSL,XLink) in order to stress the separation of the information content from presentation. The basic idea is to define a general hypertext structure in order to create pages dynamically using a structured description of the domain knowledge and a model of the current user.

Adaptive hypermedia technologies and XML techniques

Adaptive hypermedia systems build a model of the goals, preference, and knowledge of each individual user, and use this model throughout the interaction with the user, in order to adapt to the needs of that user[Bru 2001]. In adaptive hypermedia literature they are referred respectively as adaptive presentation and adaptive navigation support

XML is designed to be the data format for the web, and at the time of writing is being used by many thousands of web-based applications. XML is a bit like HTML, the format used for web documents, but it’s focused on representing data, rather than describing the presentation of data. Presentation of the data comes using XSL and navigation of hyperlink comes later, using XLink. Also XML is independent from a specific platform and operating system and provides the DOM(Document Object Model) as a platform- and programming language-independent API for the development of the
necessary tools. XML grammars can be constructed in a way that they easily can be extended by new or alternate elements. There already exists a metadata scheme for teaching resource – IMS projects [IMS2001].

**Design of adaptive educational hypermedia system**

The adaptive hypermedia system architecture (see Figure 1) consists of three main components. Such as a student model that represents the student knowledge, a domain model that contains the domain knowledge information structured in topics and relationships, and a adaptation model that is responsible for creating pages dynamically by using the information contained both in the domain and in the user modules.

XML is a meta-language that allows us to create specialized markup languages for specific purposes [XML1999]. For example, it is possible to create a tag `<TOPIC>` (and the closure tag `</TOPIC>`) that identifies a particular knowledge element.

![Figure 1: System architecture](image)

For implementing our adaptive hypermedia system we have implemented two languages:
- the Domain Structure Markup Language (DSML) in order to describe the knowledge general structure,
- the Student Model Markup Language (SMML) used by the system in order to describe the student model status.

In particular we have implemented two different Document Type Definitions (DTDs) that define the fixed structure of the two above mentioned markup languages. In the following two subsections we will give some examples of the new tags that we have introduced. Finally in the last subsection we describe the Adaptation Model.

**Domain Model**

To be dynamically processed, the domain knowledge has been structured into topics and each topic is associated to a page. Each topic is characterized by:
1) a title, 2) a set of main keywords, called concepts, 3) a set of conditioned relationships, 4) a set of explanations, 5) a set of possible examples, exercises, etc.

Therefore a link from a page to another one represents a relationship between the two topics. We have considered six different types of relationships between topics:
- super/sub that is a bi-directional relationship between a topic and all its sub-topics
- next that is a relationship between a topic and the next topic to learn
- contrary that is a bi-directional relationship between a topic and the "opposite" one. example that is a relationship between a topic and an example that explains it
- widening that is a relationship between a topic and a study in depth of it
- exception that is a relationship between a topic and an exception or a particular case
The first relationship defines the hierarchical structure of the knowledge domain. Knowledge is represented as a tree in which each node identifies a topic and a root topic is defined. The next relationship represents the sequence of topics suggested by the teacher. All the other relationships create irregular connections between topics that transform the original tree-scheme in a graph. The student can navigate the graph following all the different types of relationships and defining a personal learning path.

Each relationship is associated to a cluster of conditions that defines which kind of requirements the student needs to follow the link. If the student model satisfies all the conditions the link is displayed. The link associated to the super/sub relation always appears without requirements. All the other links can be conditioned, and in particular the teacher links can have different arriving pages in function of the student model status. In this way each node is associated to a set of next links, each one valid under a different set of conditions. The condition scheme is organized as follows.

Each condition is divided in different condition terms composed with and and/or operators. We have considered that students are classified in three stereotypes and we have associated to each argument that needs to be known a stereotype and a certain minimum knowledge level. So that a condition term can be read as: "if the student of a level X have got a knowledge level Y on the argument A, then the condition term is true". By composing condition terms with and/or operators we can obtain complex didactical requirements.

The DTD that describes DSML contains the definition the following tags:

<ADAT></ADAT> is the root of the adaptive hypertext. The <ADAT> tag can contain different <TOPIC> tags. By using <ADAT> attributes the author can also define the TITLE, the AUTHOR name and other proprieties of the hypertext. <TOPIC></TOPIC> represents a topic and is identified by using the attributes TITLE and ID; each <TOPIC> can contain different relational tags (<PARENT> and <SUBTOPIC> described below), different conditioned elements (introduced by using the <CONDITION> tag) and different <CONCEPT> tags. <CONDITION></CONDITION> defines the requirement needed to follow a certain link or to give a certain explanation. Nested <CONDITION> tags can be used to realize and between different conditions; an attribute OR associated to a <CONDITION> tag is used to realize an or between this condition and the following one. Each set of nested conditions contains an <EXPLANATION> or a relational tag. <EXPLANATION></EXPLANATION> contains the real explanation of the topic. The <EXPLANATION> tag can contain any HTML tags. This choice lets one use different media to give the explanation to the student. <CONCEPT></CONCEPT> defines a keyword associated to the <TOPIC> tag that contains the <CONCEPT>. <EXAMPLE></EXAMPLE> defines a particular kind of topic that can be used as an example of a certain <TOPIC>; a <EX-LINK> relationship links this <TOPIC> to the <EXAMPLE>. <EXERCISE></EXERCISE> defines an exercise. The <EXERCISE> tag contains a <TEXT> a <SOLUTION> and an <HELP> tag.

The following code fragment represents a simple example of the DSML tags.

```xml
<TOPIC> Topic Title
<CONCEPT> Keyword</CONCEPT>
```

Figure 2: example of domain knowledge structure
Three different type of tags are used:

- **<CONCEPT>**: that includes the keyword related to the topic.
- **<CONDITION>**: this tag indicates a didactical requirement. In this case there is a very simple condition based on the student's knowledge level. Here an expert level (USER_LEVEL=3) is required. The student model, illustrated in the next section, manages values of the USER_LEVEL variable.
- **<EXPLANATION>**: this tag includes the real explanation of the topic. Text between this tag and its closure can be written in HTML.

Other tags are defined in order to describe relationships between the topics and in particular:

- **<SUPERTOPIC>** and **<SUBTOPIC>** are used to represent the super/sub relationship. We have used two tags to describe the relation, one for each direction. **<NEXT>** is used to define the next relationship and represents the path suggested by the teacher; the previous topic is dynamically computed. **<WIDENING>** defines a widening relationship. **<EX-LINK>** represents the relationship between a **<TOPIC>** and an **<EXAMPLE>** related to it. **<CONTRARY>** defines a contrary relationship. **<EXCEPTION>** represents an exception relationship.

### Student Model

The student model is a structure maintained by the system with the aim of being able to respond to the individual student's learning style and deliver customized instruction. There are different ways to approach the student model problem. The most commonly used student modeling technique in adaptive hypermedia systems is the overlay model [Ek11997]. In this model, the student knowledge is considered an overlay of the domain knowledge and is frequently represented as a set of concept/value pairs. For each domain model concept the student model stores some values that estimate the student knowledge level of this concept. This model assumes that the student knowledge is a subset of the knowledge domain described by the teacher and cannot capture different knowledge conception. In spite of this, the overlay model is commonly used in the adaptive hypertext field because the content of the adaptive hypertext itself can be considered as a description of the entire domain knowledge. This involves that the student can be represented simply overlaying the hypertext structure.

Other adaptive hypermedia systems use simple stereotype model [Ek11997]. Student knowledge is represented as a set of concept/value pairs (as in overlay model), but the values are not completely independent. The student can be assigned to one or more class (called stereotypes) and each class is identified by a fixed set of concept/value pairs.

On the other hand the most part of the Intelligent Tutoring System [And1995] are developed using a representation of the student's knowledge based on student bugs and misconception. The buggy model represent the student's knowledge in terms of deviations from an expert's knowledge. The system classifies each student error and then uses this information to predict the student's behavior in future situations. The buggy model is really useful in learning-by-doing systems in which the system needs to monitor a student activity (as for example, exercises solving procedure).

To implement the student model we have used a mix of the overlay model and of the stereotype model. The overlay model has been implemented associating to each topic a value that weights the level of the student knowledge of that topic. This evaluation is given measuring the time spent reading the topic and the number of visits. Each time the student requests a page, then the associated value is updated.

We have also classified possible students into three different stereotypes: expert user, medium-level user and beginner user. This evaluation refers to all the arguments of the domain model and is a general assessment of the student ability. We have used a scheme based on three stereotypes referring to different system described in well-known literature [Wen1987, Ek11997]. Anyway our system can recognize each set of integer values as a stereotype scheme.

The student model is realized using two DTDs: the former defines a structure that contains the user's logins and the related passwords, the latter defines the structure for the SMML in order to describe the personal student...
model file. The DTD that describes SMML contains the definition of the following tags: 

```
<MODEL></MODEL> defines all the visited topics described by using different <VISIT> tags and a 
<LEVEL> tag. <VISIT> is used to represent a visited topic; the argument is specified using the TOPIC 
attribute. <LEVEL></LEVEL> and <LEVELT></LEVELT> define respectively the general level of the 
student knowledge using the DEGREE attribute and the level of knowledge specific of the topic. <LAST> 
defines the last visited topic. <NUMVISIT></NUMVISIT> defines the number of times that the student has 
visited this topic page.
```

A simple example of student model is the following:

```
<MODEL>
  <LAST topic="1">
    <LEVEL degree="0">
      <VISIT topic="1">
        <LEVELT>O</LEVELT>
        <NUMVISIT>1</NUMVISIT>
      </VISIT>
    </LEVEL>
  </LEVELT>
</LAST>
</MODEL>
```

The example shows the student model of a beginner level user (LEVEL DEGREE=0). In the <MODEL> 
structure there is only one VISIT tag meaning that the student has just run the hypermedia and has visited only 
the first page identified by the topic="1". The LAST visited topic is obviously the number "1". The example 
shows the student model of a beginner level user (LEVEL degree="0"). The nested tags <LEVELT> and 
<NUMVISIT> identify respectively the level of knowledge of the topic and that the student visits this topic 
and for the first time.

It is worth to note that the student models are automatically created and managed by the system so that the 
SMML is used only by the system to store relevant information.

**Adaptation Model**

The Adaptation Model (AM) creates the pages of adaptive hypermedia on the basis of the Knowledge Domain 
Model and the Student Model. The general architecture of AM consists of four main components: the User 
Action Management Module (UAMM), the Adaptivity Management Module (AMM), the Domain Model 
Management Module (DMMM) and the User Model Management Module (UMMM).

The UAMM interprets the student's behaviors sending information to the other modules (e.g. possible changes 
to Student model status to the UMMM; student's request of a page to the AMM).

The DMMM retrieves topics from the knowledge domain model on the basis of the student's requests and 
interactions. The UMMM updates the student model sending the related information to the other modules. The 
AMM adapts the presentation of the domain knowledge to the user; creating hypermedia pages dynamically. In 
particular each time a condition is found, the AMM asks the UMMM the Student Module status in order to 
solve the condition and create the new page on the basis of the topics already known by the student (provided 
by the DMMM) and of his knowledge level.

**Implementation and Results**

We have described the developing of two new markup languages that allow us to describe complex knowledge 
structures. It's worth to note that the system is designed in order to realize adaptive educational hypermedia, but 
it can be used for every kind of adaptive hypermedia thanks to the flexibility of the used structures.

Our adaptive hypermedia system has been implemented using a client-server scheme based on HTTP. The 
server application that automatically produces personalized XML pages has been described in the previous 
sections. The client is a common use browser, Netscape and Internet Explorer that can evaluate and display 
XML pages. Before starting the navigation in the adaptive hypermedia system, the user has to identify himself 
with a username and a password. The server uses this information to store the appropriate student model (or to 
create a new student model for a new user). Then, each time the student asks for a new page, the browser asks 
for it to the server side application that compute the content of the page dynamically on the basis of the student 
model. A Java applet, which communicates to the server application all the events generated by the browser, 
updates the student model status.

We are currently testing an adaptive hypermedia system on programming, created with XML dynamic support, 
that is developed for a university undergraduate program course. This test has underlined different aspects of
the system that need to be improved

In particular we are working in order to improve the student model and the user interface. We are working on the student model to insert: an entry test in order to evaluate the initial level of knowledge of the student. This feature can improve the value of the DEGREE attribute to the LEVEL tag that implements the stereotype student model. A set of tests related to each main topic in order to modify the LEVEL tag associated to each topic. This feature can improve the overlay student model. Evaluation tests can be closed answer tests, exercises that need to be solved, every different type of evaluation procedure that can give back an integer evaluation. The solving procedure associated to the exercises of the evaluation test can be monitored using every type of user model. Moreover we are working on new user interface features to improve the navigation tools in the adaptive hypermedia system [Pas1992].

Further works will consider the implementation of an authoring tool that will allow teachers to structure the domain knowledge without introducing the tags directly. This tool should be a graphic editor for developing adaptive hypermedia courseware.

Collaborative Teachback with a Statistical Cognitive Tool: A Formative Evaluation

John D Bain
School of Curriculum, Teaching and Learning, Griffith University, Australia. Email: J.Bain@mailbox.gu.edu.au

Ken Mayor
Department of Psychology, University of Southern Queensland, Australia. Email: mavork@usq.edu.au

Abstract: A learning environment is described in which students collaborate in small groups to develop screen movies in which they use a statistical cognitive tool to interpret published research and to demonstrate their understanding of least squares statistical concepts. Evaluation data are reported which indicate that, although some groups thrive in this environment, other struggle to cope. Enhancements are proposed based on the outcome of the evaluation.

The teaching of applied statistics to social science undergraduates is a much discussed topic (Becker, 1996), no doubt because it presents a disproportionate challenge to students, many of whom do not have extensive mathematical preparation. Although various teaching methods have been adopted, many use prepared data sets in which relationships between variables are to be revealed (and tested for significance) through analyses undertaken by the student (****). In recent years the data sets have been related to research-based scenarios (e.g., Derry et al., 1995; Fischer, 1996; Thompson, 1994), and the analyses are performed with one of a growing number of computer packages which have user-friendly interfaces and powerful graphing capabilities (e.g., DataDesk, SAS/JMP, SPSS, Statistica, Models 'n' Data, Statview).

The approach upon which the present work is centred shares several of these features (exercises anchored to published research, use of a computer program in the learning process, heavy emphasis on graphical representation), but it differs in several important respects:

- the data are created and altered by the student using a graphical rather than spreadsheet interface
- the emphasis is upon modelling—and playing “what if” with—the relationships between the variables represented in the program
- the students’ task is to demonstrate an understanding of statistical and research concepts by recording a screen movie, with voice-over, in which they ‘teachback’ what the statistical and research concepts mean and why they are relevant to the research scenario
- the students work in small groups (2-4) to develop and record their teachback movies.

This paper provides details of the teaching/learning arrangements for this approach to statistics, and reports a formative evaluation of the learning process and outcome.

The Computer Program

The program upon which the learning process is centred is BivarDescribe, a Macintosh program designed by the first author. This program enables users to explore the least squares properties of correlation, regression and one-way analysis of variance (anova). Consistent with calls for regression and anova to be taught as variants of the general linear model (Thompson, 1993), anova is treated as a special case of multiple regression, and the focus is upon how the relational structure of the data is modelled by the least squares approach, not on sampling distributions and statistical significance. Thus the program is intended to redress some pervasive misconceptions, namely: that anova and correlation are different procedures (Keppel & Zedeck, 1989; Thompson, 1993); that the concept of ‘explained variance’ (or ‘predictable variance’) only applies to correlational data (Hays, 1981; Huberty, 1987); that statistical significance is more important to research interpretation than effect size (Rosenthal & Rosnow, 1985; Thompson, 1993; Wilkinson et al., 1999); and that omnibus anova adequately models relational structure in a one-way design (Rosnow & Rosenthal 1989; Thompson, 1993).
As already noted, this program differs from statistical analysis programs because it facilitates the creation of data (by clicking the 'dot' cursor on the data plot) and the alteration of data (by dragging data points to new locations, or altering variances with a 'variance change' tool). An example of the main plot window in which a data point has been dragged to an outlying position is provided in Figure 1.

Figure 1. The main plot window of BivarDescribe depicting a positive linear relationship between two variables, Severity of Eating Problem and Neuroticism, but with one data point dragged to an outlying position.

Some of the additional features of this program are:

- the strength of the relationship or effect size (the Proportion of Predictable Variance) is represented by a vertical meter that changes dynamically as points are added or altered
- users may access additional information about applicable statistics by opening mini-windows in which the statistics are defined algebraically and illustrated numerically
- there is a dynamic coupling between the graphical and numerical states of the program (points selected or changed in one are selected or changed in the other)
- users may use the Enquiry Tool to see how scores are predicted or to view the deviations with which predicted and residual variances are calculated
- the user can specify a linear prediction and compare it with the least squares regression line
- a correlational design can be converted to an anova design
- contrasts between the conditions of an anova design can be specified graphically and turned on and off to see how they contribute to the predictable variance
- anova as a special cases of regression can be seen in additional window which shows the prediction of scores from the weights defining each contrast.

The Course Context

The course in which the present project is embedded is a one semester second year course in research methods for psychology students at The University of Southern Queensland. The content includes a wide range of research design and methods concepts, for which the supporting text is Shaughnessy, Zechmeister, & Zechmeister, (2000), as well as the statistical concepts involved in bivariate regression, multiple regression and analysis of variance, for which the supporting text is Keppel & Zedeck (1989). In addition, there are extensive course notes (the course is also offered in external mode) and lectures and tutorials. The exercises with which BivarDescribe is used comprise 25% of the assessment for the course. Students are prepared for the exercises during several tutorials in one of which they develop and rehearse a simple teachback movie. Students also have access to demonstration movies made with BivarDescribe.
by the authors (about 8 hours in total duration). These movies are based on a research study not included in the exercises, and their topic structures differ from those required by the exercises (to avoid direct modelling).

The Learning Process

The intended learning process consists of several interdependent activities:

- The 'priming' of relevant statistical and research concepts by viewing the demonstration movies and using them as analogues, not direct models, for the exercise movies.
- The construction of statistical understanding using BivarDescribe as a cognitive tool with which “[l]earners themselves function as designers using technologies as tools for analysing the world, accessing information, interpreting and organizing their personal knowledge, and representing what they know to others.” (Jonassen & Reeves, 1996, p. 694).
- The mapping back and forth between real research variables and relationships and their representations in the statistical domain (Derry, Levin & Schauble, 1995; Laurillard, 1993)
- Collaboration in small groups to encourage the development and refinement of understanding (Roschelle, 1992)

The Intended Learning Outcomes

The learning outcomes of most relevance here are focused on the ability of students to understand and use least squares statistical methods to interpret data within a realistic research setting, as manifested in the teachback movies created by each group. ‘Understanding’ in this context has several aspects: (a) the ability to map a research question into a statistical framework and vice versa; (b) the ability to translate flexibly between the graphical, algebraic and arithmetical representations of statistical relationships with a clear sense of why they correspond and what they mean (i.e., the understanding should be ‘relational’ rather than ‘instrumental’ —Skemp, 1976); (c) the ability to explain how basic least squares concepts apply to correlation and anova (Thompson, 1993); and (d) the ability to ‘perform’ understanding rather than to reproduce it (Perkins & Blythe, 1994) as a consequence of the ‘teachback’ format (Pask, 1976).

Evaluation

The aim of the evaluation reported here was not to determine whether the learning model outlined above is better than others reported in the literature, but rather to determine whether it is functioning much as intended and to suggest improvements (Bain, 1999). Accordingly, data were collected about the learning process (by video-recording the discussions of participating groups and coding for key features of the process) and about the learning outcome (by coding the teachback movies submitted by each group).

Participants

Eighteen groups (54 students) completed the assessment for the course, of which 10 groups agreed to take part in the evaluation (i.e., agreed to have their discussions video-taped). Four of the ten participating groups dropped out of the evaluation early, leaving 6 groups from which the present data were obtained. Most groups comprised 3 students, the range being from 2 to 4.

Teachback Exercise

Two substantial exercises comprised the assessment for the teachback component of the course, for each of which several teachback movies were to be produced. The data reported here are for the first of four movies in the first exercise for which the research scenario was based on the article by McFarland (1989). The scenario asked students to contemplate a study examining the relationship between religious orientation (as measured by the Quest self-report scale) and a scale measuring a general tendency to discriminate (Discrimination) consisting of attitudes toward several minority groups. The expected relationship was inverse, given the findings reported by McFarland—i.e., the higher the
score on Quest, the lower the Discrimination score—but this was not stated in the scenario outline. The first movie was specified as follows:

*Use BivarDescribe to model the data pattern (relationship) predicted in the scenario, showing the appropriate variable labels and scales. Initially assume a fairly weak relationship, and show what that might look like. Then:*
- refer to the Proportion of Predictable Variance (PPV) indicator to describe and explain the strength of the relationship that you have created
- open the PPV window and explain what the predicted scores are and what the proportion of predictable variance means
- apply the Variance Change tool to the grand mean (using increasing as well as decreasing modes) and describe and explain (a) the changes in the data and (b) what happens to the Least Squares Coefficient (LSC) and PPV indicators
- make sure you tie all your explanations back to the scenario study and discuss the meaning of the data patterns in terms of the scenario variables.

**Procedure**

Our intention was to record two learning sessions, one early and one late in each group’s preparations for an exercise so that improvements during learning could be documented. However, for logistical reasons this proved impossible to arrange, so the data reported below are for one session conducted part way through the preparation for the exercise. The session was recorded with a split screen format that enabled the group members to be seen as well as the details of activity on the computer screen. The teachback movies comprising an exercise were recorded when the group indicated that it was ready to do so, typically 2-3 weeks after preparations began. The recording was managed by a tutor who operated the recording software (Snapz Pro 2), leaving the group free to concentrate on producing its teachback movies. The video recordings and teachback movies were coded by a project assistant using a 5 point scale ranging from ‘not at all’ through ‘poor’, ‘limited’ and ‘adequate’ to ‘excellent’, where the descriptors for each point on the scale were contextualised to the characteristic being rated. The coding process involved repeated checks with the senior author about the codes assigned to each case.

**Findings**

The means reported in the 2nd last column of Table 1 indicate that the groups were better able to effect the intended social aspects of the learning process (discussion and collaboration) than they were able to use the resources to construct their understanding of statistical concepts (building understanding with BivarDescribe and correcting misunderstandings being rather limited). However, these general trends are qualified by substantial differences between the groups, two (F, G) being conspicuously sound, two adequate (E, J) and two others obviously struggling to cope (D, K). Similar patterns were evident when general and specific aspects of understanding were coded (Table 2). In this case it was possible to use the same scales to code understanding during the learning processes as well as in the teachback movies, and the mean data and ranges are reported in Table 2. Although the mean values on both sets of scales were mostly in the ‘limited’ to ‘adequate’ range, this pattern masks the fact that there were marked differences between the groups much as was evident in the process scales: the ranges provide some idea of the performance differences involved, although not the consistent patterns of group performance (space limitations prevent reporting of the group data).

Another aspect of the consistency of group performance is the degree of correspondence between the understanding ‘profiles’ (pattern of scores on the understanding scales) obtained during the learning process and evident in the learning outcome. An index of profile similarity is provided by the Euclidean Distance measure (Table 3) which varies from zero when the profiles are identical to an empirical maximum when the profiles are most dissimilar. As is evident from Table 3, the understanding profiles of the groups were relatively similar between the preparation sessions and the teachback movies. In other words, the level of understanding reached about mid-way through group discussion was similar to the understanding evident in the final product. This suggests that further assistance is needed to ensure that knowledge construction continues to grow as groups discuss their approaches to the teachback movies.

**Future development**
The evaluation data reported here (and supported by the other data collected) indicate that some groups were able to construct their understanding in the intended manner, two groups in particular being conspicuously capable, but at least two groups (and maybe also those groups which withdrew early in the semester) were not able to perform to a satisfactory standard. Three enhancements may assist such groups in the next offering of the course:

- there will be more extensive lead-up work in the lab to encourage greater fluency with the software and statistical concepts before the teachback exercises begin in earnest;
- a more useful retrieval and playback interface for the demonstration movies will be available: statistical and research concepts and associated movies will be accessible with a zooming concept map built with TheBrain technology (http://www.thebrain.com), and the movies will be indexed with subheads in a synchronised text window to allow ready access to relevant subtopics;
- students will be able to seek the advice of a tutor when they reach an impasse in their exercise discussions, an option not provided in the present implementation.

The Catalyst Initiative: Integrating Support and Development through Collaboration

Background
In 1994, the Provost charged three top-level administrators at the University of Washington (UW) to "do something about technology." They collaborated with faculty, librarians, technologists, and students, and gathered resources from wherever they could to bring technology into the service of teaching and learning in a more systematic way, first with the Center for Teaching, Learning and Technology (CTLT), established in 1996. By 1998, drop-in visits to the CTLT had increased dramatically, seriously taxing staff resources. At this point, staff conducted thorough assessments with faculty, librarians, instructors, and teaching assistants who expressed three overriding needs: technology support that is smooth and easy to use, flexible, and scalable. The Catalyst Initiative was created to meet these objectives.¹

The Catalyst Initiative
The Catalyst Initiative, a result of collaborations between many partners, provides UW instructors with four levels of support for integrating technology into their teaching: 1) the Catalyst Web site, 2) Catalyst Web Tools, 3) face-to-face consultations at the CTLT, and 4) Catalyst workshops. The Catalyst model provides the grounds for a symbiotic and iterative relationship where the support activities feed and lead to partnerships, which in turn result in the development of more and better support resources and activities.

The Catalyst Initiative is carried out by a permanent staff that understands the needs of both instructors and the units on campus with a stake in teaching and technology. This staff, called the Educational Technology Development Group (ETDG), is perfectly situated to arrange collaborations and bridge gaps between educators and other units on campus. This position as an intermediary and a change agent has allowed ETDG staff to not only develop a scalable support strategy but to participate in high-level experiments that push the boundaries of innovation.

Partnerships
Excellent support resources and exciting technology infused teaching practices are found all across campus, but few people know about these resources and practices beyond their own departments. The Catalyst Initiative was created to identify and make these resources and practices visible, scaling innovation across campus through collaborative partnerships. Resources and materials generated from these partnerships are placed on Catalyst and co-branded, giving credit to the partners who helped create them.

The co-branding strategy allows staff to maintain current and innovative resources on Catalyst and to use them in the workshops and one-to-one consultations in the CTLT while alleviating the burden of generating new materials whole cloth. Informal partnerships also yield tremendous benefits. Instructors who use the Catalyst Web site, attend workshops, seek help at the CTLT, or use the Catalyst Tools offer feedback which is incorporated into all parts of the Catalyst Initiative. Not only do these strategies leverage resources, but they also forge a sense of ownership and a measure of comfort with educational technology among faculty and support staff who come to see themselves in the offerings on Catalyst.

Catalyst Web site (http://catalyst.washington.edu)
The Catalyst Web site provides examples, promotes good teaching practices, builds technology skills, and makes technology easy for instructors to use.² Catalyst places good teaching and student learning at the forefront, treating technology as a means to these ends. The resources on the Catalyst Web site shape and inform the other levels of the Catalyst Initiative: Catalyst workshops, one-on-one consulting delivered in the CTLT, and Catalyst Web Tools. This interlocking support strategy ensures that campus educators receive clear, consistent help for integrating technology into their teaching.

A great deal has been written about the creation of the Catalyst Web site,³ but it is worth reemphasizing that its homegrown content is built solely through collaborative partnerships with campus teaching practitioners. A look at the six major content categories on Catalyst makes clear the close connections to campus instructors: 1) Profiles tell stories of educators who are using technology in teaching; 2) Teaching lets instructors explore the ways that technology can help achieve specific teaching and learning goals; 3) Action Plans are "road maps" for particular tasks, such as creating a class Web site; 4) How-to pages take users step-by-step through specific tasks needed to make technology work; 5) Learning offers information on CTLT workshops and other campus activities related to teaching with technology; and 6) Web Tools is a gateway to Web-based software and also links to innovative uses of Catalyst Web tools by UW educators, again helping to spread good practice beyond disciplinary boundaries.

Leveraging the expertise available, the ETDG staff has collaborated with specialists on campus to create the following pages and tools with partners:

- **Distance learning courses:** UW Educational Outreach co-developed Catalyst content that helps faculty design distance-learning courses.
- **Evaluations, Web-Ed forums, how-to documentation:** The Program for Educational Transformation Through Technology works with ETDG staff to evaluate the Catalyst Web Tools, to post streaming video from the Web-Ed forums on the Catalyst Web site, and to contribute how-to documentation.
- **Online journals:** UW Libraries’ co-branded content explains how to locate and link to online journal articles.
- **Accessible Web sites:** The UW DO-IT office is working with the ETDG staff to integrate accessibility issues into the content on the Catalyst Web site.
• **MyUWClass: Computing and Communications (C&C)** is currently working with the ETDG to create **MyUWClass**, a personalized teaching portal for UW instructors. This portal integrates Catalyst Web Tools with course and student information systems and applications that let instructors post content directly to the Web. C&C will also continue to collaborate on technical documentation.

The Catalyst Web site fulfills the three needs expressed by faculty and staff during the foundational assessment period. First, the varied stories of teaching with technology, the step-by-step instructions, and the best practices make an educator's initial foray into educational technology smooth and easy. Second, Catalyst is extremely flexible; faculty needs and wants vary markedly across departments, disciplines, and course types, but the Catalyst Initiative allows them to pick and choose support options that suit their environment and needs. Finally, the Catalyst Web site and Web Tools are a campus-wide resource, available 24-7, which scales local solutions throughout the campus teaching community.

The Catalyst Web site is widely used by UW faculty--instructors and staff view upwards of 100,000 pages per month. Clearly, the Catalyst Initiative has reached instructors from a wide range of departments.

**Catalyst Web Tools**
The ETDG created the Catalyst Web Tools to allow educators to add advanced content to their Web pages without learning complex programming languages. The Web Tools themselves are all founded in the wants and needs expressed by UW instructors and are constantly updated according to their feedback and suggestions. For example, the Political Science Writing Center asked the ETDG staff to develop a tool that would allow students to review each other's work. After determining that the tool could be used campus wide, ETDG developers created PeerReview. As more instructors use the tools, they ask for more features and additional functionality and, indeed, new tools. The current set of nine tools allows instructors to easily create threaded discussions; receive student assignments online; manage ListProcs; facilitate case-based learning on the Web; receive anonymous feedback; administer one-question surveys, online quizzes, and peer reviews; and even create course Web sites entirely through a Web browser from any computing platform. Instructors have requested over a dozen more tools, which will be assessed, prioritized, and developed. The next in line is MyUW Portfolio, an online portfolio system that students will use on their own and with guidance from faculty, advisors, and career counselors.

Because the tools are based on feedback from instructors and may be used by people in every department, they are popular with UW educators. More than 4000 instructors have used Catalyst Web Tools, and learners log in to use the tools more than 100,000 times every month.

**Drop-in visits to the CTLT**
Every year, 1700 instructors on average visit the CTLT for assistance with integrating technology into their courses. The Catalyst Web site supports these activities, and their face-to-face feedback often leads to the development of new content, tool features, and workshop materials.

**Catalyst Workshops**
Over 900 instructors attended the popular Catalyst workshops last year. The workshop materials and topics are continually modified as a result of feedback received from workshop attendees.

To take advantage of the expertise available beyond the small ETDG staff, several of the workshops are co-taught by the staff and specialists from other campus organizations. For example, an instructor from Educational Outreach team-teaches a workshop on developing a distance learning course, and the DO-IT office works with ETDG staff to integrate accessible design issues into the workshops and co-teaches an accessibility workshop.

**Summary**
The Catalyst Initiative's wild success is the result of the innovative model of working with partners—both formally and informally—to create support materials and resources that scale campus-wide. Using four levels of support ensures that instructors have access to support that suits them, support that is created from their own suggestions, wants, and feedback.

Abstract: Many new technologies are now available for delivering and/or providing access to computer-based learning (CBL) materials. These technologies vary in sophistication in many important ways - depending upon the bandwidth that they provide, the interactivity that they offer and the types of end-user connectivity that they support. Invariably, appropriate combinations of the available technologies are needed in order to produce the most effective and efficient learning environment for any given application. Bearing this in mind, it is important to consider how multimedia resources, interactivity and global connectivity can best be used in order to produce a software product that best fulfils the requirements identified in any given courseware requirements specification. In this paper we discuss the types of model that are needed to create effective interactive, multimedia courseware. We also indicate the nature of the interactions that exist between these models and the ways in which these can be used to optimise the trade-offs that are inherent in the creation of multimedia CBL materials.

Introduction

Multimedia computing technology has opened up many interesting opportunities for the creation of new types of learning and training products covering a wide range of subject areas for many different audiences (Barker, 1996; 1999). Examples of the types of product include: electronic books; educational games; interactive products based on the use of compact disk (CD) technology; intranet and World Wide Web pages; and tools to facilitate 'electronic' knowledge sharing. Together, products of this sort can be used to enrich the scope and quality of computer-based learning (CBL) experiences.

Within the remainder of this paper we shall use the term 'interactive multimedia courseware' to refer to computer-based learning products in which some skill or knowledge is intentionally transferred to a user of that product as a consequence of its use. Such software can be defined in terms of 'learning products' in which optimal combinations of text, sound and images are used to achieve particular learning outcomes using interactivity in various ways to achieve these objectives. Typically, interactivity is used: to facilitate navigation through the corpus of materials that make up the product; to provide assessment and feedback mechanisms; and to facilitate communication between the group of users that constitute the 'learning community' at which the product is focused.

When designing courseware, it is important to consider how multimedia resources, interactivity and global connectivity can best be used in order to produce a software product that successfully fulfils the conditions identified in any given courseware requirements specification. Because of the complex nature of both software development and the cognitive processes that take place during learning, this is no easy task. The design and development processes therefore need to be guided by appropriate models that encapsulate 'best practice' with respect to both system design and implementation issues. Relevant pedagogic models also need to be employed in order to ensure that the subsequent learning processes are relevant to the knowledge and skills that are to be acquired. Therefore, in this paper we shall discuss the types of model that are needed in order to create effective interactive, multimedia courseware. We also indicate the nature
of the interactions that exist between these models and the ways in which these can be used to optimise the trade-offs that are inherent in the creation of multimedia CBL materials.

**Underlying Models and Methodologies**

There are two basic approaches to developing courseware products; we shall refer to these as the 'empirical approach' and the 'theoretical approach'. The first of these uses a strategy that is based essentially on a 'trial and error' procedure; that is, a learning product is produced and its effectiveness is determined; if necessary, an iterative 'fine-tuning' mechanism is then used in order to improve it. In the second approach, appropriate theories and models are used, in so far as they exist, in order to create a learning product that falls directly within a given 'region of acceptability'. This latter approach is attractive because it reduces the amount of uncertainty involved in product creation. It is our opinion that design and development models (and methodologies derived from them) should play a fundamental underlying role in guiding the production of interactive multimedia courseware. The underlying importance of these basic tools is reflected schematically in Figure 1.

![Diagram of models and methodologies]

These range from simple models, such as the 'waterfall' model to more advanced models and methodologies including: the CASE approach, SSADM, the spiral model, Siegal's approach, December's methodology, Dinucci's method, and so on. However, these models and methodologies are mostly used in the development and implementation of business-oriented information systems and are not normally suitable for the development of multimedia learning products.

Designing and developing multimedia learning products necessitates close co-operation between people with specific skills and expertise. Furthermore, the existence of diverse modes of storage and delivery necessitate the adoption of appropriate methodologies and suitable design models in order to create high quality learning products. In the remainder of this paper we shall discuss some of the more important issues relating to the formulation of the various models and methodologies that we feel are needed in order to underpin the successful development of interactive multimedia courseware products.
Problems Arising in Multimedia Development

The development of interactive learning products usually requires a team of skilled specialists. Whilst many of these teams adopt their own approaches to the analysis, design and development of their products, there are no generally accepted models and methodologies specifically designed to assist in the creation of multimedia learning products. As the complexity of the products and the size of the development teams increase, it becomes more difficult to manage the production process efficiently. Most existing models and methodologies stress the importance of operation, providing information, handling events, and so on. However, these elements are not so important in courseware development, where the process involves the integration of all the available resources into a single piece of software. In this situation, the emphasis is on how to present a topic to users in a way that increases their knowledge and/or skills.

A multimedia project is normally composed of four equally important components: planning and design; resource and program development; testing and evaluation; and dissemination. Ideally, if we had adequate models, it would be possible to predict exactly how much time should be spent on each of the four phases. Invariably, the time spent on each individual phase is not equal and is often not predictable. In reality, many multimedia projects spend a much greater proportion of time on resource and program development and relatively little time on planning and design, testing and quality control, and dissemination and evaluation. Neglecting these major elements of the project life cycle could ultimately lead to a deficient product.

Of course, there are many other reasons why multimedia projects fail. For example, in a survey of the members of one multimedia development team, the three main factors contributing to unsuccessful projects were identified as: poor design; ineffective project co-ordination; and inefficient communication channels. Undoubtedly, most of these arise due to lack of a structured approach. In the following section of the paper we introduce a comprehensive methodology that is designed to improve the efficiency and effectiveness of multimedia development teams.

A Methodology for Creating Multimedia Learning Products

There are several good arguments in favour of adopting a sound methodology for developing multimedia learning projects. These include the necessity for good communication; consistency; effective quality control strategies; and accurate cost estimation. Some of the important issues that need to be addressed are outlined below.

Project Planning: the scope of a project, its budget and its intended completion date are usually negotiated prior to the commencement of any development activity. Once a project is formally agreed upon, management strategies are identified, milestones are established and tasks and resources (including individual team members) are identified.

Team Management: effective team management helps to establish a productive working atmosphere, deals with problems more readily and shares the workload efficiently. Figure 2 shows the structure of a typical multimedia development team in which the courseware designer and project manager co-ordinate the planning, design, development and testing. A clear definition of the roles and responsibilities of each team member ensures that all project tasks are allocated and allows contingency plans to be put in place in the event of any member of the team becoming unavailable.

Project Life Cycle: Figure 3 shows the four main phases involved in a typical multimedia project. The first three of these (preparation, design and development) are iterative processes. The fourth phase (dissemination) can be repeated if the product is revised or modified between releases.

Analysis of Requirements: a comprehensive project analysis determines the specific requirements of the end-product and should include an in-depth study of the users, the intended delivery systems and the scope of the project. These should be documented so that developers and clients can refer to them in order to ascertain whether the product is meeting the required standards.
Design Specifications: the design specifications provide a detailed description of the program requirements to all members of the development team. It incorporates essential information such as the font sizes to be used, colour palettes, file formats and flowcharts that outline the proposed content.

Human-Computer Interface (HCI) Issues: the end-user interface encompasses a number of factors including the proposed screen layouts, navigation controls, user interaction, 'look and feel' and the nature of the various metaphors that are embedded within the courseware.

Delivery Medium: multimedia learning products can be delivered in a number of ways. For example, CD-ROM publication, the Internet, an intranet or local area network, and various types of turnkey solution. Each delivery method has constraints and limitations that should be addressed at the planning stage of the project.

Resource Production: multimedia learning products can contain a combination of text, graphics, audio, video and animation. The establishment of appropriate parameters for each of these at the outset of the project avoids inconsistencies within the final product.

Program Integration: the ease with which multimedia elements are integrated depends critically upon the availability of a comprehensive script and detailed flowcharts to assist the programmers and resource producers. A good file naming strategy is also essential to the integration of resource files.

Quality Control and Evaluation: both formative and summative evaluation strategies need to be identified during the planning stage and quality control should be regarded as a continuous process. A thorough testing strategy should be established that allows all errors to be noted and amended effectively. Ongoing testing and evaluation should be employed throughout Phases 1, 2 and 3 in order to ensure that the final product falls within a pre-specified 'region of acceptability'. As we discuss later, 'ongoing evaluation' is an important aspect of the dissemination phase of the methodology.

Documentation: good documentation is essential to ensure that any project life cycle evolves efficiently and within the allotted time. The basic documentation required for most multimedia projects comprises: a project proposal; design specifications; scripts and storyboards; quality control and testing strategies; and progress reports.
Scripts and Storyboards: scripts are paper-based documents that provide a detailed description of the courseware content and how this is to be implemented within the final product. Scripts contain details of all on-screen text, audio transcripts, written descriptions of graphics, video and animation along with their file names. These form the basis of audio scripts, graphics listings and video and animation storyboards. Scripts also provide special instructions and detailed flowcharts for the programming team.

Dissemination: the dissemination phase of product development involves all the processes necessary to package the product and make it available to customers. Of course, even after a learning product has been
released for distribution (see Phase 4 in Figure 3) it is important to undertake a programme of 'ongoing
evaluation'. The results of this type of evaluative study can subsequently be used to fine-tune future
releases of the learning product and also inform the design and development processes involved in the
creation of new courseware products.

Discussion

One of the most convincing arguments for the use of models stems from the fact that they enable us to
make accurate predictions about the properties and behaviour of the systems that they describe. In this
paper we have described a methodology to facilitate the development of interactive multimedia learning
products. The methodology that was outlined in the previous section has been derived primarily from our
experiences with conventional multimedia learning products involving the creation of interactive CDs. It is
therefore necessary to discuss whether or not the methodology (as presented in Figure 3) could be applied
to the development of other types of interactive learning product - particularly those involving the use of an
intranet or the World Wide Web. Our experiences to date suggest that the basic methodology (with some
minor amendments) would easily handle this latter type of product. Essentially, Phases 1 through 3 could
be used as they stand. So far, we have found that the only area where minor amendments may be needed is
in Phase 4. In this phase, the 'replication' and 'packaging' steps may be less important for an
intranet/Internet project than they would be for a CD project. We are therefore optimistic that the proposed
methodology can be used to cater for a wide range of interactive multimedia learning product development
projects.

Conclusion

Developing interactive multimedia courseware products is a complex and costly process that requires a
wide range of powerful models and a workable, practical design and development methodology. In this
case, a structured design and development approach has a number of advantages. For example,
templates and scripts provide essential information in easy-to-read formats that can be tailored to meet the
requirements of individual team members. In addition, the production process can be made simpler and
more efficient - as fewer program and resource changes are required at the development stage.
Furthermore, quality control is made more effective by providing testers and evaluators with a program
'blueprint'.

A learning product development methodology, such as the one that has been described in this paper,
should enable multimedia courseware products to be developed in a more predictable way - both in terms of
learning outcomes and from the perspective of resource utilisation (time and money). Implicit in the
various project phases that we have described in our methodology are a number of local and global
interactions - both between the underlying models and the system variables that are involved in managing
the preparation, design, development and dissemination processes. It is through a greater understanding of
these interactions that we will be able to gain further, much needed, insight into the various factors that are
responsible for causing multimedia learning projects to fail.

Abstract: the electronic dissemination of information via computer networks is having a considerable impact on educational institutions in terms of the mechanisms that they are able to employ for course delivery. As a result of this, the number of courses that are taught electronically through the Internet and/or the World Wide Web has increased considerably over the last few years. Such courses require two fundamental types of resource: appropriately designed electronic course materials (for students to study) and a network of online tutors who can provide active support, advice and encouragement for students. This paper discusses the nature of the skill sets needed by online tutors in order to fulfil their roles effectively and efficiently within an online learning community. Some mechanisms for acquiring these skills are also briefly discussed.

Introduction

Electronic teaching through the Internet and the World Wide Web is rapidly becoming an established practice in many educational institutions. This is particularly the case in situations where there is a need for flexible course provision and/or a demand for ‘time and place’ independence of course delivery (Beckstrand et al, 2001; 2002). Non-academic institutions are also using ‘e-learning’ techniques as a mechanism for facilitating staff training, reducing the costs of training, improving the effectiveness of educational delivery and providing continuing professional development opportunities.

Naturally, designing electronic courses for online delivery is, in many ways, different from the ways in which conventional courses are developed and used. Indeed, according to Galpin (2001), ‘simply taking a traditional classroom or paper-based experience and putting it online is not enough’. Techniques for designing and supporting online courses are well-documented in the literature - see, for example, Thomas et al (1998), Lockwood and Gooley (2001) and Jolliffe, Ritter and Stevens (2001). Our own approach to electronic course design and delivery has been described in detail elsewhere (Barker, 1999; 2000; 2001; 2002). Essentially, the methodology involves the creation of four basic types of resource. First, an online corpus of study material (a teaching web) that students can access through an intranet or via the World Wide Web. Second, the use of computer-mediated communication to facilitate both synchronous and asynchronous computer conferencing activities. Third, the creation of shared workspaces to facilitate collaborative group working. Finally, the provision of appropriate assessment infrastructures to enable students (and staff) to monitor and gauge the progress they are making with the course.

Obviously, online teaching is different from face-to-face instruction. The main differences between the two approaches arise because teachers and students are not physically present together at the same geographical location. This absence of ‘proximal presence’ has two important effects, which are briefly discussed below.

First, the shared environmental artefacts that may be present in a face-to-face teaching situation (such as walls and windows, posters, desks, books, students, and so on) are usually ‘absent’ from a distributed online teaching environment. Of course, within an online system, virtual analogues of these ‘missing’ objects may be generated in order to substitute for them. However, many of the more common approaches to online teaching do not do this due to the complexity of the software that is needed.

The second ‘missing component’ from online teaching environments is the various types of body language that are normally associated with small-group, face-to-face teaching situations. Within online teaching, various textual conventions are sometimes used to substitute for the absence of non-verbal communication – for example, the use of emoticons, various font styles for representing different modes of expression (such as the use of coloured text,
italicisation, and so on) and iconic forms. However, these conventions have only met with various degrees of success (Yazdani and Barker, 2000).

Because online teaching is different from face-to-face instruction, it therefore requires different skill sets - both for the students who use the electronic resources (Montieth and Smith, 2001) and for the staff involved in supporting the various activities associated with a particular course (Duggleby, 2000; Salmon, 2000; Bennett and Marsh, 2002). Because of the growing importance of electronic course delivery and online tutoring, the remainder of this paper attempts to identify and discuss some of the staff roles and responsibilities associated with online teaching and learning - and the skill sets needed to undertake these activities.

Possible Roles for Online Tutors

Within environments that utilise electronic course delivery, there are a number of different course 'development and delivery' scenarios. These are likely to require instructors to play several different roles. Bearing this in mind, Table 1 depicts some of the major roles that any particular individual may have to fulfil in relation to producing and/or using an online course.

Table 1: Roles for Online Tutors

| - a member of a course design team
| - the sole designer of a course and one of its online tutors
| - an online tutor for courses produced by others
| - a moderator and/or examiner for various courses

It is easy to deduce from Table 1 that there are three basic types of involvement that an online tutor might have with any given online course. First, in the development stage, a tutor might become involved in various aspects of designing (and possibly, producing) an online course. Second, in the delivery stage of a given course, particular individuals (who might not have been involved in the development phase) might act as an online tutor for that course. Third, in the assessment phases of a course the tutor might be involved in various quality assessment or quality assurance activities.

Each of the above roles will have an appropriate skill set associated with it. Each skill set will require an appropriate mix of pedagogic, technical and organisational skills. The nature of these three skill sets is discussed in more detail in the following section of the paper.

What Skills are Needed?

In order to undertake their responsibilities in an effective way, online tutors will need to be equipped with the skills and knowledge needed to perform the tasks that they are required to undertake. The detailed nature of these tasks is discussed elsewhere (Barker, 2002; Duggleby, 2000; Salmon, 2000). This section of the paper therefore briefly describes and discusses the three major skill sets (pedagogic, technical and organisational) that we believe are a necessary pre-requisite for effective online tutoring.

(a) Pedagogic Skills

Skills in this category relate to the ability of an online tutor to design and create teaching and learning materials for online use. There will normally be two contexts in which these resources might be used. In the first instance, they could form the primary resource set that students use in order to study and learn. Alternatively, they could constitute an ancillary resource set that is intended to complement a primary resource set that has been produced by someone else. Some of the important pedagogic skills needed to facilitate the design and development of these learning resource sets are listed in Table 2.

Most of the necessary skills in this category will be similar to those needed to prepare and use conventional teaching and learning resources. For example, topic research, knowledge structuring and the design of self-study tasks and assessment strategies are fairly generic activities that are applicable to virtually all modes of teaching. Naturally, it will be necessary to consider what special requirements need to be accommodated as a consequence of
using web-based delivery. This is especially so in the case of knowledge structuring - where electronic resources can be interlinked in many different ways that are not feasible with conventional media. Of course, the use of electronic resources also offers many pedagogic facilities (such as animation and interactivity) that may not be possible using conventional approaches to instruction.

(b) Technical Skills

The skills in this category relate to the ability of an online tutor to use a range of different software tools in order to conduct his/her tutoring tasks in an effective and efficient way. Some of the more important of these tools are listed in Table 3.

Table 3 Technical Skill Requirements for Online Tutoring

Although online tutors often use telephone, facsimile transmission and postal services in order to communicate with their students, by far the most important (and heavily used) mechanisms of communication are computer-mediated. Undoubtedly, electronic mail is probably the most widely used tool. This is used both to send ‘simple’ messages and ‘compound’ messages containing various types of attachment - such as text files, spreadsheets, sound and image files, multimedia documents, and so on. A variety of different computer conferencing tools (both synchronous and asynchronous) are also usually employed to facilitate teaching and learning tasks. These electronic tools, and the others identified in Table 3 are discussed in more detail elsewhere (Barker, 2002).

(c) Organisational Skills

Skills in this category refer to the ability of online tutors to organise their own activities as well as those of the students who are following the particular courses for which they are responsible. Some of the main skill requirements in this category are listed in Table 4.

Table 4 Organisational Skills for Online Tutors

</table>
As is the case in conventional teaching situations, one of the major organisational responsibilities that online tutors have to undertake is the facilitation of students' learning activities - especially for group work and projects. A useful way of achieving this is through the use of an electronic 'noticeboard'. Such a tool can be used to publish lists of students and details of group activities - for example, project specifications, milestones, deliverables and time schedules. Tools of this sort can be regarded as being a part of a broader organisational toolset that is provided within the framework of an 'electronic office' environment. Many organisations involved in electronic teaching and learning especially within a virtual campus context now provide their network of online tutors with this type of facility - see, for example, the facilities at the Robert Gordon virtual campus at http://campus.rgu.com.

Skill Acquisition Mechanisms

Any discussion of the skills that an online tutor needs to possess must also consider how these skills might be acquired. Naturally, there are two major issues that need to be discussed. First, we must consider how 'new' online tutors gain the skills that they need in order to participate in an effective way within an online learning community. Second, we should consider how established online tutors participate in 'professional updating' activities - that is, the mechanisms that they use in order to keep up to date with the new software systems, technologies and course modules that they may be required to use.

Ideally, the mechanisms for each of the above skill development processes should be found embedded within the online learning communities themselves. That is, the organisations responsible for providing courses for students should also provide online training opportunities for the network of tutors that is needed to support these courses. Many distance learning universities do in fact provide online courses and online training for their staff. The UK's Open University (OU), for example, uses its computer network infrastructure in order to provide online, interactive training for many of its tutors. As an example of this, the OU makes available online training for the FirstClass conferencing system (which it uses for many of its distance learning courses).

Many other universities also provide various online courses both for their own staff and for other people who want to find out more about electronic distance learning and online tutoring activities. The 'virtual campus' at the Robert Gordon University in Scotland (http://campus.rgu.com), for example, has a number of online courses that visitors to the campus can study - see, for example, the 'Campus Induction Module'. This module shows users how to: build an online office; access and use course materials; enter online discussions; join an online community; and use the virtual library. It also provides a series of 'top tips' for online learning.

The need for professional development opportunities for staff in the area of online learning, tutoring and distance education has been recognised by a number of authors - see, for instance, Salmon (2000), Montieth and Smith (2001), MacKenzie and Staley (2001), Bernath and Ruben (2001) and Bennett and Marsh (2002). Based on the results of their study into using a virtual campus, Montieth and Smith (2001: p. 126) report the finding that 'It is in the area of computer mediation we consider staff need more training ... staff skills with respect to mediation through CMC do require updating'. Bennett and Marsh (2002) have reported similar findings. They suggest that '... the majority of tutors new to online teaching do not have the background of online learning experience upon which to draw ...'.

Various mechanisms for the provision of online training opportunities for academic staff have been explored. For example, in their research, Bernath and Ruben (2001) have described the use of a 'Virtual Seminar in Distance Education' for facilitating training opportunities. This is an online, asynchronous discussion forum (based on the World Wide Web) that was designed to provide university faculty and administration with professional development in the field of distance education. The success of their research leads one to suggest that the provision of online training opportunities for online tutors is of paramount importance. This view is supported by the findings of Bennett and Marsh (2002) who have described their experiences in preparing 'new' online tutors for the roles they will play within an online electronic learning community. Their study outlines the nature of the training given to potential online tutors and how the effectiveness of this was evaluated. The results of their evaluation suggest that the 'online teaching practice may be the single most important element of the training and development process'.

Naturally, as the roles of academic staff in higher education institutions change, there is obviously considerable scope for the introduction of online training courses that can provide adequate and appropriate skill development for the new tasks that tutors have to undertake.
Using Online Learning for Skill Acquisition

One important approach that we have used for developing the skills needed to become an online tutor is through on-the-job training using an 'apprenticeship' model (Barker, 1994). In this situation, potential online tutors become involved in running tutorial and teaching groups in conjunction with an experienced and/or 'qualified' e-tutor. Another approach, that we are exploring, involves the creation of an online environment for facilitating skill development. The architecture for our proposed training facility is illustrated schematically in Figure 1.

![Figure 1: Skill acquisition environment for an online community of trainee e-tutors.](image)

There are four important components within the skill development system: the knowledge corpus that documents the skill sets and procedures to facilitate their acquisition; an electronic performance support system (EPSS) that is able to assess the ability of a potential tutor and his/her current knowledge/skill levels and then recommend a 'course of study' for that tutor; various online presentations that are designed to facilitate knowledge/skill acquisition; a range of practice conferences; and a discussion forum. The latter two resources are particularly important because it is through these that new tutors can practice their skills, discuss any problems that they are having and share their experiences.

Conclusion

For a variety of reasons, many academic (and non-academic) institutions are now becoming involved in electronic learning initiatives. There are two main 'driving forces' underlying the developments that are taking place. The first of these arises as a result of the need for many organisations to become involved in computer-based distance education involving the Internet and the World Wide Web. The second arises as a result of organisations wanting to take advantage of the many pedagogic benefits that online learning can bring. A computer-based network infrastructure (such as the Internet or an intranet) is able to facilitate two major educational objectives. First, the delivery of electronic learning resources in a flexible way that is independent of 'time and place'; and second, the realisation of 'educational conversations' between students themselves and with their tutors. Naturally, with the growing demand for online learning, it is important that students following particular courses are supported by an adequately trained network of online tutors. Such a requirement necessitates that we should identify the skill sets that online tutors need and then provide appropriate (online) infrastructures and mechanisms to enable the requisite skills to be developed. This paper has attempted both to identify some of the required skills and to suggest how the training mechanisms might be realised.

Abstract: This paper describes approach, methodology, and potential application areas for agent technologies in Command and Control (C2) performance and primarily focuses on the development of agent-based constructed forces. The platform involved is the AWACS-AEDGE™. This is a distributed, real-time team decision support environment comprised of simulators, entity framework, intelligent agents and user interfaces. The AEDGE is constructed as a federation of intelligent agent-based functions that enable user-friendly scenario construction, emulation of friendly and hostile entities, and dynamic scenario control. Its architecture and decision making algorithms are examined, as well as agent technology and utilization in the realms of constructive forces, synthetic team members, and decision support.

Introduction

This paper describes the approach, methodology, and potential application areas for agent-based synthetic task platforms (STE) to enhance C2 performance, as exemplified in the AWACS-AEDGE™. We focus particularly on the development of agent-based constructed forces and decision support to enhance C2 training and performance (Barnes et al, in review).
The Airborne Warning and Control System (AWACS) Weapons Director (WD) team serves as a vital airborne Command and Control (C2) node, providing airborne surveillance, control, and communications functions for tactical and air defense forces. It is clear that AWACS WD duties exemplify core characteristics of a C2 team. They perform in highly interdependent roles, tracking and coordinating some type of tactical action, in a manner consistent with overall strategic goals and procedures, for a defined sector of air and/or land space over a sustained period of time (Elliott et al., 2001). To accomplish this, they exchange, interpret and effectively weight information and optimize resource allocation decisions across team members. As a prime example of a command, control, and communications paradigm, the AWACS team is an area where C2 research has often centered.

The Air Force has recently focused on investigations and enhancement of operational expert training through an internet-based research infrastructure to enhance Distributed Mission Training (DMT). The USAF DMT program is national in scope, with the goal of enhancing operational training through the use of high-fidelity military simulation systems that are networked using secure, classified systems. The DMT-Research Net (DMT-RNet) project, the subject of this paper, is a local project that will support DMT through basic research accomplished using PC-based systems networked through the Internet. The project will establish an I-2 based infrastructure for collaborative research and training, along with identification of specific research issues related to enhanced skill acquisition and operational performance. This research will guide improvements in the operational USAF DMT training environment.

The USAF DMT project relies on a network of highly realistic battle simulators that allow expert operators to train in a virtual battlespace across a highly secure and classified communication network. In contrast, the DMT-RNet project is developing less expensive PC-based systems that can run in unclassified mode on I-2. This allows the PCs to be distributed and deployed as training systems in almost any setting. It also allows research to be conducted in nonclassified environments, using these simulation systems that reflect essential components of operator expertise. For example, multiple universities and research companies can and have been networked to enable real-time multidisciplinary collaborative research.

As a pioneering technology, DMT-Rnet shows how other collaborations in research will be possible. Other universities, agencies, and companies will be able to link up to similar sorts of networks and pool their talents and resources to produce high level research. The applications of these concepts and technologies to other realms are nearly limitless, as future research will show to be the case (Barnes, Elliott, & Entin, 2001).

This research network has thus far developed two platforms. The initial phase of the DMT-RNet project utilized the dynamic distributed decision making (DDD) team-in-the-loop simulation environment (Hess, MacMillan, Elliott, & Schiflett, 1999; Kleinman and Serfaty 1989). An internet-based version of the DDD was developed, the DDD Network (DDDnet), which allows players in distributed locations to connect and perform a distributed mission in real time. The DDDnet is an internet-ready version of a Linux-based collaborative gaming space that connects players to each other and to others, such as observers, confederates, trainers, or researchers. In the DDDnet observers at any location in the network are able to observe the scenario play in real time. They can view the screen display and electronic communications of any player, and communicate to one another via email or voice. In addition, the DDDnet can connect players to one another for interactive mission planning, debriefings and after-action reviews.

The second platform developed is the AWACS-AEDGETM (Agent Enabled Decision Guide Environment). The AEDGE is constructed as a federation of intelligent agent-based functions that enable user-friendly scenario construction, emulation of friendly and hostile entities, and dynamic scenario control. The remainder of this paper goes into the detail of this platform and the agent technology that it employs.

It has been stated that advanced technology in itself is not a training system and should not be seen as a training solution (Salas, Cannon-Bowers, & Kozlowski, 1997). We are in complete agreement. The purpose of this effort was to build a platform with advanced-technology features that will augment, enable, and/or investigate new approaches, methods and measures in training and performance research.

AEDGE™

The Airborne Warning and Control System (AWACS) Weapons Director (WD) team serves as a vital airborne Command and Control (C2) node, providing airborne surveillance, control, and communications functions for tactical and air defense forces. In this paper, we describe development of an agent-based C2 team decisionmaking platform for research and training, the AWACS-AEDGETM (Agent Enabled Decision Guide Environment).

AEDGE, AWACS-AEDGE, and 21CSI are registered trademarks of 21st Century Systems Inc.
The AWACS-AEDGE, built using 21st Century Systems Inc.'s AEDGETM infrastructure, is a distributed, real-time team decision support environment comprised of simulators, entity framework, intelligent agents and user interfaces (Barnes et al, in review). The environment supports a wide variety of air, sea (surface and sub-surface), and ground assets in a combat environment (Chiara & Stoyen, 1997), primarily based on the roles and responsibilities of AWACS WD team members. The environment has been tested with an excess of two hundred physical entities (planes, ships, SAM sites, etc.) operating with realistic yet non-classified performance characteristics in an interactive environment in which real-time decision support is available to each WD.

The behavior and decisionmaking of all hostile and friendly entities not controlled by humans is directed by agent-based technology. If a human decides to “log in” as a particular entity, he/she may choose to view recommendations generated by the agent for that entity. Even if the human operator chooses not to view recommendations, the agent recommendations are still logged by the computer. This enables direct comparison of human to agent decisionmaking. We expect these capabilities will facilitate skill acquisition, decision making, skills assessment, and human/team performance modeling.

AEDGE agent capabilities enable more detailed and innovative approaches to measurement and modeling of individual and team workload, communication and decision making. Tracking the number and type of recommendations generated by the agent at any given time contributes toward new ways of conceptualizing and representing cognitive workload of individuals and teams. Agent-based recommendations may also serve as a standardized benchmark by which human tactics and decisions can be compared. In addition, the AEDGE platform can operate through speech – operators can speak to the system using predefined jargon, request tasks be performed or information provided/transfered, and the agents will respond verbally to the speech-driven requests, using voice generation technology. All agent communications to each other, as well as to humans, are transcribed, logged to data output files, and are available online.

The AWACS-AEDGE was conceived through cognitive and functional analysis of team member roles, responsibilities, and decisionmaking (Dalrymple, 1991), to optimize generalizability of results to operational settings. Systematic descriptions of AWACS roles, responsibilities, requirements, interdependencies, tactics, strategies, and task demands were collected from subject matter experts, cognitive task analyses (Fahey et al., 1998; MacMillan et al., 1998) and focal-group interviews (Elliott et al., 1999; Elliott et al., 2001). These data were examined to identify decision events, which were generic to performance, regardless of mission scenario, and likely to bottleneck under high tempo situations.

AEDGE architecture

The AEDGE product is based on an extensible distributed component-based architecture, which defines entities, agents, players/users, and their interactions. The interaction and communications among AEDGE elements are based on the Service Provider/Service Requester protocol (SPSRP), using flexible services and messages to exchange information among any two components.

In SPSRP, Service Providers implement a number of services and register service-templates with a Component Registry, which maintains the location of all components and the services provided or required by each. The registry is used by Service Requesters to locate components that provide the services required by the requester. After the requester is matched with one or more Service Providers, a direct connection is established between Service Providers and Service Requesters. This prevents the Registry from being a service dispatcher and a potential bottleneck. Let us consider the interaction between users (via user interface components) and agent components. In most cases users will interface with specialized Agents, called Agent Managers. The managers are designed to coordinate, synchronize and manage the work of multiple “worker” agents. Without an Agent Manager, the user will need to interfaces with each “worker” agent individually, while using the Manager, the user is able to issue higher-level requests (e.g. “Send me your current recommendations”) by letting the Agent Manager (who knows the capabilities of its workers) to distribute and correlate individual agent tasks.

The Service Requester then sends Service objects directly to one or more Service Providers, who respond with ServiceResult objects. A Requester may wish to subscribe for service updates, in which case, the Service Provider will send a Message object to the requester every time it needs to advertise an update; it is up to the Requester to respond to that message by requesting the actual update (i.e. data is advertised, not pushed, to avoid client-side congestion).

The user may trigger a request for recommendations, which is sent to the Agent Manager via a Service request object. After receiving the request, the Agent Manager finds the best-suited collection of agents to perform the job (it may take one or more worker agents) and forwards specialized Service requests to each of them. The worker agents formulate their responses (usually, sets of recommendations and rationale) and send them back to the Agent Manager.
via ServiceResult objects. The Agent Manager may correlate (and even remove redundant or inconsistent recommendations) all service results and then sends the combined set of recommendations to the user, again via a ServiceResult object. The user interface component then knows how to extract the recommendations and present them to the human user for evaluation.

**AEDGE decision making algorithms**

The AEDGE architecture provides multiple levels of agent-based algorithms. Generic resource allocation, search and optimization algorithms are a core part of the AEDGE product. Each AEDGE application can use and further extend these fundamental agent algorithms by either providing parameters and applications-specific values, functions and rules, or by combining, modifying or supplying new algorithms. All new and modified algorithms must comply with a well-defined agent interaction interfaces, similarly to the generic algorithms.

The AWACS-AEDGE extends resource allocation, optimization and other algorithms with AWACS WD-specific objective functions and constraints. For example, the AWACS weapon-target allocation algorithm, based on a generic resource- allocation with heuristic function evaluation, defines extended constraints such as Table 1.

Similarly, the AWACS weapon-target allocation algorithms define objective and cost functions for any potential allocation and let the generic allocator agent arrive at a (near-)optimal set of weapon-target pairings. The objective functions are based on the individual target values (as well as other factors, such as target priorities, probabilities for success and so forth) and cost functions are based on the risk for the team if the allocation is to be committed.

Further, the AWACS-AEDGE agents use the extended algorithms as a model of the desired WD performance. Thus, the agents are able to generate a set of recommendations pertinent to a particular tactical position and the events that lead to it – agents do keep even history. Such recommendations can either be presented to the user (who may choose to accept or ignore them) or be used for internal evaluation of the user's performance as a function of the similarity of recommended-action versus actually-executed-action. A new application of the agent recommendation analysis involves the measurement of AWACS WD cognitive workload based on the volume and complexity of agent recommendations at any given time (Chaiken et al, 2001).

To enhance the utility of AWACS-AEDGE as a decision support tool, recommendations must not only be presented to the user in an unambiguous and intuitive manner, but in some cases they may need to be pre-processed to ensure that the human user can maintain strong situational awareness and be alert. For example, in periods of exceptionally high-activity, unsupervised agents may tend to generate large number of recommendations that will be confusing and even detrimental to the human performance. The Agent Manager must thus not only coordinate and synchronize recommendations, but also prioritize and reduce the number of presented recommendations to only the top-most critical ones.

Further, the AWACS-AEDGE agents use the extended algorithms as a model of the desired WD performance. Thus, the agents are able to generate a set of recommendations pertinent to a particular tactical position and the events that lead to it – agents do keep even history. Such recommendations can either be presented to the user (who may choose to accept or ignore them) or be used for internal evaluation of the user's performance as a function of the similarity of recommended-action versus actually-executed-action. A new application of the agent recommendation analysis involves the measurement of AWACS WD cognitive workload based on the volume and complexity of agent recommendations at any given time (Chaiken et al, 2001).

To enhance the utility of AWACS-AEDGE as a decision support tool, recommendations must not only be presented to the user in an unambiguous and intuitive manner, but in some cases they may need to be pre-processed to ensure that the human user can maintain strong situational awareness and be alert. For example, in periods of exceptionally high-activity, unsupervised agents may tend to generate large number of recommendations that will be confusing and even detrimental to the human performance. The Agent Manager must thus not only coordinate and synchronize recommendations, but also prioritize and reduce the number of presented recommendations to only the top-most critical ones.

**Table 1: Decision Making Algorithms**

(Chaiken et al, 2001). Conversely, in periods of lull, artificially increasing the number of recommendations may help keep the human alert and situationally aware.

**Utilization**

In the AEDGE, the experimenter can control the autonomy and configuration of the decision aide agent. If the agent is allowed to make all decisions, the scenario is effectively being run independently of any human intervention. This allows (a) assessment of reliability of recommendations, (b) assessment of effects of uncertainty in a dynamic environment, and (c) investigation of “what-if” scenarios, where algorithms underlying recommendations are manipulated.

The aide is, and should be, configurable. First, it needs to be configurable in order to maintain effectiveness. The manner in which decisions are made can and will change according to the particular mission scenario and rules of engagement. The software allows variations in its rule structure. It also allows changes (in real-time) to the perceived value and priority of various assets and targets. This enables fine-tuned research in decision process, as the agent can be
tailored to be more or less risk-taking (when information is uncertain), have directional bias (more or less "aggressive", "passive" in threat assessment or rules of engagement), or bias in central tendency (decisions are always "moderate"). In addition the probabilistic nature of the environment can be manipulated by specifying the probability that the decision made will be successfully executed. When that probability is very high, the environment is deterministic and very reliable. When probabilities are lowered, scenario events will unfold in different ways, each time the scenario is run.

Configurable decision algorithms enable in-depth descriptive and prescriptive investigations of decision process. Particular heuristics, biases, and models of decision choice can be predicted and compared to algorithm function. Results from descriptive investigations can inform refinement of the decision tool. In turn the algorithm can be modified to reflect a particular decision model, and compared to other models with regard to the degree to which either model accounts for performance data. For example, threat assessment decision events have been shown to be sensitive to order effects, in that information presented first or last (depending on tempo) is given more weight, even when other information is more important. The algorithm can be adjusted to reflect this tendency, and results compared to actual data. Other facets relevant to the decision process can also be investigated with this approach, such as risk-taking, aggressiveness, and information uncertainty.

Discussion

Despite agent limitations, we expect the AWACS AEDGETM to enhance research, training, and performance in complex high-tempo scenarios. The aide as decision support is particularly useful where multiple decisions must be made within a short time frame or where an "out-of-the-ordinary" event must be spotted among numerous seemingly normal processes. The aide has the advantage of complete reliability regardless of stress, sustained operations, or consequences of failure. It will never forget to refuel a plane because of a tense situation occurring at a different part of the scope.

While the usefulness of the DSS function is apparent, the potential utilization of this platform for training and performance research is its greatest asset. The benefits of this general approach to STE-based research is detailed elsewhere (Schiflett & Elliott, 2000). To summarize briefly, the AWACS AEDGETM was developed to primarily to support trainers and researchers. In fact, every characteristic and feature within this platform was developed in order to empower trainers and researchers with regard to methods, measures, manipulations, and transfer of training. First, internal validity is enhanced by providing researchers with more detailed performance measures, increased scenario realism, ease in generating scenario events, agent-based performance models, and comprehensive data output files. In addition, further control is provided to team performance researchers through the provision of synthetic team members—thus allowing investigations of performance within more highly controlled team contexts. It provides trainers with online scenario revision capabilities and visual online performance feedback for operators. Finally, this system was developed to enhance external validity—the degree to which research transitions to the operational performance environment. This was accomplished through comprehensive cognitive task analyses of the operational performance domain. While use of this system is no guarantee of good training or research per se, we hope it will accomplish its purpose—to provide tools that empower experts to more easily accomplish research and/or training goals.

Technology and Collaboration: A Qualitative Study in one Secondary School in Botswana

Introduction
Technology use in Botswana schools is relatively new compared to many other parts of the world, and because of its financial implications the decision to implement it had to be weighed against many other pressing needs such as access to basic education, food and shelter. However, improving the quality of education is one of the top priorities for the country mainly because education has been heavily criticized for failing to better prepare students to work and participate in their society. In 1994, the Revised National Policy in Education (RNPE) was released and the policy stated that computers be introduced in schools so as to help enhance learning and also help the country in its transition from an agro-based economy to an industrial one. Computers in Ledumang were introduced in 1997. These computers are used for different purposes. There is a course called Computer Studies, taken by only a few students because of the limited number of computers. The course is aimed at equipping students with different computer skills that would be useful for them once they leave school. Computers are also used in different subjects to assist learning.

Purpose of study
The purpose of this study was to investigate the kind of learning that takes place when computers are used, and also find out the roles that both the teacher and students play in the classroom.

Significance of study
Computers have been introduced in schools as an effort to improve learning and one of the ways through which we can find out if this is happening is by examining how students and teachers interact with these computers. Such knowledge is very useful for educators in determining whether technology is playing any beneficial role in education.

Description of site.
The school under this study is called Ledumang Senior Secondary School. The school is located in Gaborone, which is the capital city of Botswana. Students going to this school are doing four and five, which are the last two grades of high school. Students in this school come from diverse educational background in terms of computer use. Some come from junior high schools which used computers, some had used computers during their primary or pre-school education, and some have had no experience with computers at all.

Method
This study engaged qualitative methodology of in-depth interviewing and participant observation to collect data. Interviews were conducted among students, teachers, headmaster and officials from the Ministry of education. Each interview lasted for about 30 minutes. The total number of participants in this study was 25. There were 15 students, 6 teachers, 1 headmaster and 3 officials from the Ministry. Observations were also made in computer-assisted classrooms while in session to get a better feel of what is happening in the classes. The study was done over a period of two months June 2001 to August 2001.

Findings of the study
Participants in this study reported a more changed environment in the classroom when technology is part of learning. Teachers reported that students are more excited and enthusiastic to learn. Collaboration came up as the most reported effect of computers in the classroom. The teachers mentioned that even though each student has their own computers to work at, they still spend a lot of time working with each other and learning from each other. Students enjoy watching over each other’s work and finding out how they do things. Most of the time students prefer to ask their classmates if they do not understand something rather than ask the teacher. The teacher just acts as a facilitator in the classroom. One teacher said “I think it is good when students work together and like this and learn from each other, but I also have to make sure that things do not go out of hand. I have to make sure that they stay on the job and do not just play around and I also have to make sure that they do not mislead each other. I encourage them to check with me if they are not very sure of what their classmates are telling them.” The students on the other hand expressed that they enjoy working with computers because they are kept so busy and the teacher allows them to freely talk with each other, do things together, which is not always something they do in other classes.

Collaboration is also enhanced outside the classroom and school premises. The teachers report that they have put up an e-mail system for students to communicate with students in other senior secondary schools in the country to discuss their work. Students also communicate with other students in the United Kingdom, which they find very exciting. This gives them an opportunity to bond with students in other parts of the world and learn from them.
Another significant way in which collaboration is fostered is through the final project that is done by form five students. At the end of their senior secondary education, students write final examinations, which mainly determine their acceptance into institutions of higher education or work places. As part of these examinations, students doing computer studies have to do a project in which they consult with local companies or government agencies and together with the help of the teacher, identify a problem that they would like to tackle and use computer simulations to work out the solution. Students work on this project pretty much for the whole year. During the whole process, students work closely with the teacher and the companies they are working for. Students get grades for this work and they also have to present their solutions to the companies and discuss their findings. This gives students a great opportunity to interact and collaborate with other people outside their school environment. It also helps to narrow down the gap between school knowledge and the outside world. In this way students can make a connection between what they learn at school and what is happening outside. The companies even hire some of these students.

Conclusion
Collaboration is enhanced when students are encouraged to work with each other. They learn to respect each other’s opinion and take criticism. These are some of the qualities that they would need once they enter the world of work. Taking learning outside the classrooms or even school premises is very important in helping students see the connection between what they are doing and real life. The teacher play a crucial role in directing this kind of learning and students on the other hand take a big responsibility for their learning.

Beyond W3C: TruVision - Enhanced Online Learning for People Blind Or Vision Impaired

Frank Bate
E-learn
frank.bate@elearn.wa.edu.au

Ron Oliver
Edith Cowan University
Western Australia
r.oliver@ecu.edu.au

Abstract: This paper describes the design and development of TruVision, an online learning environment designed to enable blind and vision impaired students to develop skills and expertise in elementary and advanced information processing strategies to enable them to seek full-time employment within industry in such positions as administrative assistants, Help Desk personnel and data entry operators. TruVision is a product within The Flexible Learning Toolboxes Project, a component of the Australian Flexible Learning Framework for the National Vocational Education and Training System 2000-2004 (AFL Framework). The AFL Framework is designed to support the accelerated take-up of flexible learning modes and position Australian VET as a world leader in applying new technologies to vocational education products and services. This paper describes the TruVision product and showcases its innovative design based on very stringent accessibility needs and guidelines.

Introduction

Online learning environments in higher education are frequently criticised for their failure to make the most of the opportunities afforded by the new technologies (eg. Dehoney & Reeves, 1999). Too often the design of the settings is constrained by such practical factors as inflexible delivery systems, the need for converged on and off-campus settings, and the quest to generate on-line courses from existing print-based materials. Rarely do developers have the opportunity, the direction and the support to plan and build high quality online learning materials. One project in Australia, however, that differs from others in this regard, is the Flexible Learning Toolboxes Project (ANTA, 2001).

The Toolbox initiative is part of the Australian Flexible Learning Framework for the National Vocational Education and Training System 2000-2004 (AFL Framework). The AFL Framework is designed to support the accelerated take-up of flexible learning modes and position Australian VET as a world leader in applying new technologies to vocational education products and services (EdNA VET Advisory Group, 2000). A Toolbox is a collection of resources, suggested learning strategies and supporting material for the online delivery of vocational education and training. The learning resources are Web-based and designed in a manner which facilitates customisation and reuse in the National Training Framework, the basis of qualifications and accreditation in the Australian VET sector.

Flexible Learning in the VET sector

National and state authorities responsible for VET within Australia have recognized for some years that developing online materials is expensive and best achieved through a collaborative approach. It was this challenge that prompted the Australian National Training Authority (ANTA) to consider strategies that could motivate and support registered training organisations (RTOs) to embrace modes of flexible delivery for their
students. A resource strategy was formulated by which sets of generic and customisable materials could be
developed and applied widely throughout the training sector. The intention was to create efficiency and
economies of scale though large scale production of learning materials capable of wide acceptance and use. This
plan became the ANTA Flexible Toolbox Project which has evolved since 1999 into the Flexible Learning
Toolbox Project of today. The Toolbox initiative was a strategy to encourage development and delivery of more
flexible learning materials for the training market – particularly for online learning.

Flexible Learning Toolboxes
The phrase “Training Package” has a specialised meaning in the Australian VET sector, referring to a nationally
endorsed statement incorporating the competency standards, assessment guidelines and qualifications relating to
training in a particular industry sector. These components are uniform at a national level but allow for a range of
flexible training pathways for achievement and assessment.

The introduction of Training Packages within the National Framework in 1998 provided a perfect opportunity
for the Australian National Training Authority to explore the concept of Flexible Toolboxes to support learning.
In the first instance, any products developed in this setting would have widespread application providing
significant economies of scale. Secondly the use of on-line technologies appeared to provide and promote the
many forms of flexibility associated with the delivery of the Training Packages in the national setting.

The Flexible Learning Toolbox Project has carried three main development stages to date, from Series One in
1999 to the recently completed Series Three. Developers bid for funding to build Toolboxes from funding
managed by the Flexible Learning Advisory Group (FLAG), a committee with strong interest and expertise in
flexible delivery in the VET sector. Teams and consortia work together to develop bids to build online learning
resources for qualifications within the national Training Packages. Teams are required to demonstrate strong
links with the industry groups and to propose online materials that demonstrate evidence of sound contemporary
learning designs and development processes that create materials with high levels of product utility. The
following descriptions from the developers’ guidelines highlight these aspects of Toolbox design:

a. Toolbox learning designs
A fundamental requirement of Toolbox resources is the need to exhibit effective teaching and learning
approaches. To support this requirement, proponents need to demonstrate their capacity to develop
resources with the following features:

- a firm basis in an educational model which recognises an active, constructive role for learners;
- learning activities which engage the learner in active processing of the subject matter rather than
  mere knowledge acquisition;
- learning settings and tasks that encourage meaningful online communication and interaction
  (between learners as well as between teachers and learners);
- content resources which are visually attractive, motivating to use and organised logically for ease
  of navigation; and
- representations of authentic and real life settings in preference to textual descriptions.

b. Toolbox product utility
A second important consideration concerns product utility characteristics. Toolboxes are expected to
allow for wide applicability across the target audience for whom they are intended. For this reason they
are expected to be flexible, portable to a range of delivery platforms, and readily customised. Desirable
characteristics include:

- the use of readily available non-proprietary development software;
- the use of HTML code where customisation can be anticipated, with more sophisticated
development software (eg Flash) reserved for components that are unlikely to be changed;
- the development of platform independent resources which allow for maximum portability to users’
delivery platforms;
- avoidance of rigid structuring devices locking the learner into one pathway through the material
  (although a suggested learning sequence may be desirable); and
- a file and directory structure that facilitates the location of a particular learning segment, or the
  selection of a single unit as well as the use of the whole Toolbox.
Toolboxes are also expected to be widely accessible. They are expected to operate on client computers running at 300 MHz and guidelines are provided to developers for aligning the Toolboxes with:

- the EdNA metadata standards;
- the W3C content accessibility guidelines (Priority 1); and
- the Preferred Standards Project.

TruVision

TruVision (http://www.elearn.wa.edu.au/truvision) is one of six ANTA Equity and Access Online Product Development projects commissioned in 2001. It is an online learning environment that has been designed to offer on- and off-line options in the vocational education sector for learners who are blind or vision impaired. Through the establishment of a simulated Help Desk entity, TruVision provides a variety of authentic, work-based online learning experiences that prepare learners for vocational outcomes in the IT industry. IT Help Desk occupations are particularly attractive to people with a visual disability.

The framework that was used to inform and guide the instructional design process is a component model, described in Table 1, which comprises three elements which represent critical components of any learning settings. In particular, the framework highlights connections and distinctions between the elements which can be made in the design of online learning settings (Oliver, 1999).

Table 1: Framework describing critical elements of online learning settings

<table>
<thead>
<tr>
<th>learning design elements</th>
<th>description</th>
<th>examples</th>

<td>Web pages, readers, textbooks, computer-based tools, Web links, notes, documents, workplace manuals, case studies, databases</td>
</tr>
<tr>
<td>learning supports</td>
<td>The scaffolds, structures, motivations, assistances and connections used to support learning</td>
<td>Learning guides, discussions, chats, suggested learning pathways, mentors, buddies, workplace trainers</td>
</tr>
</tbody>
</table>

The framework provides a means to isolate and study the various elements within learning settings and suggests emphases which can be made in the instructional design process. Contemporary learning theories posit that the forms of learning design most appropriate to higher education are those based on constructivist learning principles. The above framework takes on particular and discrete forms when applied this way.

In the context of the instructional design for the TruVision setting, authentic tasks were used as the organising framework for the learning process. Students are provided with realistic and relevant tasks which they are required to complete. In order to assist them in completing the tasks, a range of learning resources and scaffolds for learning are provided. The learning setting is comprised of these carefully chosen learning tasks and learning supports to scaffold learners as they undertake them. The content in the setting takes the form of a variety of learning resources which are organised within the virtual office setting in much the same way as the learners will find resources in the workplace.

Design Considerations

With most online settings, the instructional design precedes any decisions about interface design. In this product, it was essential to marry the two so that the learning setting would provide the accessibility required. The design of TruVision needed to go beyond compliance to W3C standards alone. In its final form, it provides an audio and text-based interface for people that are totally blind so that they can hear the learning context and interactions through a combination of screen reader and streamed audio. In addition, TruVision interprets this audio and text-based interface with a graphical version for people with vision. In this way, two versions of the
learning environment are provided on each and every web page, both of which are invisible to the other. The concept is represented as Figure 1.

Hidden interpretive text for screen reader software (eg Jaws).
Audio link extracted from Flash
Navigation links extracted from Flash
Common HTML, Word documents etc

Figure 1: The TruVision Design Model

The TruVision Setting
The task of designing for the range of vision impairment and adaptive technologies was complex. The following sections of the paper explain the design considerations underpinning TruVision, and demonstrate how educational design decisions were taken.

Figure 2: Authentic learning tasks
TruVision is a learning environment based around authentic tasks. The learners find themselves immersed in a virtual workplace and undertake tasks and activities which accurately reflect how they will need to apply their learning in the workplace. Assessment, activities and resources are closely aligned with the learning outcomes that are sought.
In order to provide accessible materials for blind and vision impaired learners, the setting makes extensive use of audio and visual materials to cater for the range of people that are vision impaired. The learners use the site with the same tools and processes that vision impaired people currently use in workplace settings.

The learning setting has been designed and built for customisation and reuse. There are many elements within to support this application including a comprehensive Teachers' Guide to assist others to implement TruVision. The Teachers' Guide provides a range of suggestions and strategies to help facilitators balance content and collaborative dimensions of online learning.

The learning setting includes a range of assessment activities to support independent and classroom learning usage. The assessment tasks include a range of formative and summative strategies as both supports and scaffolds for learning. The assessment tasks also provide strong measures of competence and achievement of course aims through the authentic tasks on which they are based.

TruVision has been designed in ways which will support a variety of instructional applications and able to support learners with a range of learning styles. The flexible nature of the setting with a separation of learning tasks, learning resources and learning supports makes it a tool that can be adapted to suit the needs of a broad range of learners and their preferred learning styles.
User-Testing
The development of TruVision was accompanied by a rigorous and comprehensive program of usability testing to ensure the product was able to meet the needs of the diverse target audience (e.g., Nielsen, 1993). A comprehensive user-testing program was undertaken as part of the design process and feedback was gathered from learners in a variety of contexts. These include learners using screen readers, screen magnification software and with learners who were using no adaptive technologies at all. This program was undertaken in collaboration with:
- The Association for the Blind of WA (Inc)
- The Royal Blind Society (NSW)
- The Royal Victorian Institute of the Blind

Coupled with the usability testing was a series of formative assessments to explore the success of the learning environment among learners who were unaccustomed to online and computer-based environments. More comprehensive testing and evaluation of the learning setting is being planned to enable its capability to serve the diverse audience to be more fully explored. This testing will also explore strategies which will enable the learners to undertake collaborative and communicative tasks and to enjoy the enhanced learning opportunities that these strategies afford sighted learners.

Conclusion
The TruVision project is going a long way to be meeting the expectations of the stakeholders in terms of innovative and accessible design. Initial feedback from learners and teachers suggests that it is a successful learning setting for the target audience and that it provides a valuable template for sound educational practice coupled with accessibility for other online product development to follow.

Utilizing the PDA as a Vehicle for User Interface Design Pedagogy

Michael E. Battig – mbattig@smcvt.edu
Computer Science Department, Saint Michael’s College
Colchester, VT 05439

Abstract

As computing and embedded systems become ubiquitous in our world, the importance of user interface design knowledge increases in our curriculum. Students of undergraduate information systems or computer science programs should possess some competence in this computing sub-discipline. However, many programs do not have the curricular space to host a separate course in usability or user interface design. To address this concern, results and observations of incorporating user interface design pedagogy in the context of a software engineering project course are presented. The project centers around a data collection application to be hosted on a PDA (Personal Digital Assistant). The application has significant constraints concerning usability and human factors that provide a rich context for teaching and demonstrating user interface design concepts.

Keywords: user interface design, usability, ergonomics, software engineering, laboratory course, PDA.

1. INTRODUCTION

While change in computing seems inevitable, educators continue to wrestle with the problem of packing more topics into a finite curricular space. Therefore, an approach that has gained momentum is to integrate some topics into the fabric of courses rather than creating individual courses for each topic [Johnson 1997]. In this work, we will investigate the goals and outcomes of integrating user interface design pedagogy into a traditional software engineering course. Specifically, we will look at the benefits and detriments of utilizing the Palm PDA platform as the focus of a semester-long student project.

The software engineering course for this project is a four-credit course taken during the senior year of a traditional undergraduate program in Computer Science. A significant component of this course is the semester long project. The project allows students to work in teams of no more than three students. The four phases of the project are: requirements specification, design specification, implementation, and test plan design and execution. Thus, the teams have the benefit of seeing a project through many typical phases of a software lifecycle.

Of particular interest is the utilization of the Palm OS® platform as a vehicle to reinforce fundamental user interface design and software engineering principles. This project concept has been employed for two consecutive academic years. The students have a background in Java/C++ programming, but no prior experience with the Palm OS® platform. The implementation and testing phases require the use of the Metrowerks CodeWarrior® IDE, which supports C++ for the Palm OS® [Rhodes 1999].
2. USER INTERFACE DESIGN GOALS

The software project in this instance is a basketball statistics data collection program for the Palm IIIc and Palm IIIxe PDAs. The program must allow a novice Palm user to track basic statistics (e.g., field goals attempted/made, personal fouls) on an individual player and team basis during the fast-paced action of a live NCAA basketball game. Therefore, the program's interface must be simple, minimize the user's memory load, provide intuitive short cuts, allow for easy reversal of actions (e.g., undo), and prove to be reliable in the real-time setting of a basketball game. Participants are given the opportunity to test their product at an actual NCAA Division II basketball game during the final week of classes of the fall semester.

During lecture, students are given the opportunity to dialog on a number of outside resources related to user interface design. Students are exposed to a variety of literature, some from the popular press [Carlton 1994] that illustrate, often in a very humorous fashion, the broad range of expertise that is common among users. Students are also given supplemental material from the traditional user interface design discipline [Shneiderman 1998, Nielsen 1993]. The following concepts are presented in this segment of the course:

- Prototyping
- Parallel Design
- Know the User
- Heuristics for Interface Design
- Usability Testing.

The students are required to develop interface prototypes as part of their requirements and design specification documents. The value of this has many facets, not the least of which is the reinforcement of demonstrating an iterative design process. Thus, we see an effective interface developing over time rather than developed in its entirety the first time. Furthermore, since each team is developing a unique interface, students may then compare designs prior to implementation in order to see the benefits of participating in a parallel design. Related to this point is the need for the instructor to communicate a relaxing of the traditional standards of academic dishonesty (i.e., we encourage the participants of this course to share ideas and to incorporate the “best of class” into their own implementation).

Classical user interface design pedagogy invariably includes the novice/expert user continuum. To apply this knowledge, students are encouraged to consider the attributes of the typical user of their system. Basketball scouts are typically assistant coaches who are novice Palm users that will use the system on an intermittent basis. Thus, many of the heuristics discussed in the course are applicable.

Simplicity of the interface is essential. For starters, the typical PDA does not provide an abundance of display real estate. Secondly, all game time features need to be placed on a single screen (navigating multiple screens during the fast-paced action is too burdensome). Student-developers are also encouraged to provide informational feedback, minimize the user's memory load, and provide consistent short cuts where possible. Given that users will invariably make input mistakes, the system must allow for the easy reversal of actions as well. The system also provides the opportunity to emulate direct manipulation versus indirect manipulation as developers are encouraged to minimize user input via Graffiti® in favor of stylus input (potentially integrating an error prevention strategy into the interface design).

The course introduces students to the differences between utilizing heuristics for user interface design (as discussed above) and actual usability testing. Although students don't typically have the time typically (nor the inclination) to recruit human subjects for usability studies, they are encouraged to give their system to a non-CS student for review. The process of looking at a software system's interface through someone else's eyes is an enlightening experience for many.

3. SOFTWARE ENGINEERING GOALS
The software engineering course that is the focus of this research is in many ways traditional. We utilize a well-known text [Pressman 2001]. We teach a variety of process models, paradigms, and techniques with an eye toward balancing theory with practice. However, after ten years of teaching this course, we have found difficult to reinforce beyond telling (i.e., our assumption is that telling is not teaching and that illuminate certain lessons that are historically students will embrace that which they self-discover through practice). Those lessons are:

- Difficulties of software maintenance
- Learning new tools/platforms
- Differentiating essential from accidental
- Applicability of non-technical skills
- Working in a team environment
- Dealing with non-contrived constraints.

The Palm project in this course gives many students their first hands-on experience with software maintenance. For most of them, the project represents their first attempt at modifying a non-trivial program written by another developer. This is accomplished with the students being given a base Palm C++ project as a jump-start. The base program includes over 1400 lines of C++ spread over four classes. The original motivation was that a typical Palm application was deemed too large for undergraduate students to develop in the context of a one semester course, given that they must develop requirements and design specifications before commencing with implementation. Students have typically added another 500 to 1,500 lines of C++ to the base project. Post semester student assessments have shown that at the conclusion of the project, students say they would prefer to write their own application as opposed to maintaining code written by someone else. Thus, we have achieved a significant learning outcome by allowing students to self-discover the hardships of software maintenance.

The Palm project also provides students with the opportunity to apply their knowledge of object-oriented software development to a novel target platform. For all of the students to date, this represents their first exposure to the Palm OS® Metrowerks CodeWarrior® development environment. Although the learning curve for a new tool causes a certain level of anxiety in most of us, the experience creates a nice backdrop to discuss the differences between the essential and accidental activities for a software project [Brooks 1986]. Thus, we are able to highlight the essential nature of many non-technical skills such as writing and speaking. Since the project includes written documents (requirements, design, test plan) in addition to source code, students are able to see first hand the essential nature of effective communication. The potential pitfalls of communication are further highlighted, some might say exacerbated, by virtue of the fact that the students work in teams.

Perhaps the most beneficial attribute of a learning experience is creating an enthusiastic atmosphere. We have found that the combination of a novel platform and a believable application provides students with enthusiasm in that they see the project as more “believable” than others that may have been contrived in the past. At the start of the term, students are shown a commercial Palm OS® application for tracking football statistics. The real-time differences between football and basketball game situations provide a nice scenario for discussing usability issues. Center stage in this discussion is the fact that football provides frequent, short breaks in the action that basketball does not permit. Fortunately, college students are almost universally aware of the differences between the games, although the presence of international students provides a ready reminder of cultural issues in software design. Thus, the elaborate multi-screen interface in the football scouting application is insufficient in this case.

4. DIFFICULTIES & DISTRACTIONS

Without question this project provides some hurdles that every team mentioned in their post-mortem survey:
Limitations of the Palm screen
Lack of implementation tools
Frustrations with maintenance.

Due to a combination of the usability demands of the application and the limited screen size on the Palm III, all development teams concluded that the challenges in user interface design were more significant than they had faced previously. Specifically, participants noted that buttons needed to be large enough to tap accurately, yet not so large as to chew up too much screen real estate. On a related note, teams also mentioned that they were challenged to come up with meaningful abbreviations for each button (e.g., "FreeTAtm" or "FTA" as an abbreviation for "free throw attempt"). For these reasons and others, the use of the PDA in this course provides a pedagogical platform that allows students to deal with interface design issues that are commonplace among practitioners.

Every team lamented the fact that they were limited to the C++ programming language and the CodeWarrior® IDE. Participants are accustomed to a richer set of interface development tools such as JBuilder® or Visual Basic®. Previous work has considered user interface design in the context of the PC [Battig 2000]. However, the PDA target environment is significantly different from the PC. For starters, the resources of memory (both primary and secondary) and processor are significantly less on the PDA. Secondly, the PDA development platform has not been around for over two decades like the PC and thus has not been the recipient of the sophisticated tools that accompany such tenure. The result is that students are given the opportunity to learn a new development platform during development in much the same way as practitioners do routinely.

On the post-mortem surveys, a majority of teams indicated that they would have preferred to develop their own application from "scratch" instead of maintaining an existing one. For most, this is the first exposure to the tyranny of software maintenance. Professional developers experience this frustration more than some care to admit. However, the constraints of the marketplace do not usually permit developers to take the time and money to build new systems, even when it seems justified from their perspective. Therefore, the project has the benefit of demonstrating to participants the difficulties inherent in software maintenance.

5. CONCLUSION

The results and observations of using the PDA platform to teach user interface design and implementation to undergraduate computing students include many benefits. Students are confronted with usability obstacles that are more challenging than most they have faced to date. For example, several project teams labeled their player buttons in sequence (from 1 to 5) instead of using the player jersey number. This example provides a poignant application of reducing the user's memory load. Although usability heuristics like this are commonly taught, one final attribute of this project merits discussion. Because the PDA platform is fairly novel (i.e., most students own a PC, but none of the participants own a PDA), it provides a "gee-whiz" factor that increases student motivation. In other words, students are more enthusiastic participants and learners in a project that they perceive is using cutting-edge technology.

The project also addresses many software engineering issues that present problems for pedagogues. Because this project is larger than the typical student project (several thousand lines of code), it presents issues of software engineering that are hard to expose in the classroom and yet are common in practice [Dawson 1997]. Chief among the software engineering issues is the difficulty associated with software maintenance.

Most computing curricula [ACM 1991, AITP 1997] recognize the importance of user interface design. However, many undergraduate programs do not have the freedom in the curriculum to include a separate course in user interface design. Therefore, the benefits of teaching usability issues in a related course (such as software engineering) prove compelling. As an added benefit, project participants begin to see the
important ways in which many usability heuristics are integrated into the fabric of user interface design, software implementation, and human relationships.

Nielsen, Jakob, Usability Engineering, 1993, Morgan Kaufmann.

APPENDIX

To give the reader a better understanding of the data collection application and user interface employed in this project, this section will highlight the evolution of the actual interface developed by one of the development teams. The user interface design changes were the result of feedback that students received from four sources: course materials on usability, direct instructor feedback, fellow classmate feedback, and outside-the-course student feedback.

Figure 1. First Prototype User Interface
Figure 1 shows the first interface implemented. This interface has numerous deficiencies. The most glaring is the memory load placed on the user to associate players on the floor with the numbers 1 through 5. Figure 2 shows the improved interface with jersey numbers providing a more natural approach. Note also that the improved version provides the ability to reverse previous actions via the “Undo” button. The latter interface includes features for two teams instead of just one. The developers of this interface also incorporated some feedback on usability to change the abbreviations used on the buttons. Notice that the abbreviation for a three-point shot attempt changed from “3pa” to “3ptAtm.”

The revised interface in Figure 2 also provides buttons for substitutes (“Subs”) and summary of statistics (“Report”). Screen shots for these features are shown in Figures 3 and 4 respectively. To make a substitution, the user clicks a player currently on the floor and a player currently on the bench and then clicks “Sub.” Figure 3 shows that Johnson will be coming off the bench as a substitution for Strickland. Lastly, Figure 4 shows the summary statistics collected for Team 2. These statistics may also be viewed on an individual player basis.

Abstract: This paper reports initial results from a study which investigated if different media combinations could be shown to improve students' understanding of computer-based learning materials and to determine whether student learning style affected student understanding for different media combinations. Three groups of participants were given a presentation, each using different media combinations to present a topic. Dual coding theory was used as the basis for designing the presentation. Results indicate that participants' understanding was enhanced when the computer-based learning materials were presented using sound and diagrams. Understanding was worse when materials were presented using text and diagrams. The result supports the predictions of dual coding theory. Furthermore, the results indicate that the sound and diagram combination can improve participants' understanding regardless of their preferred learning style, and that intuitive learners seem to be exceptionally volatile to different media combinations.

Introduction

Many researchers of educational technology agree that learning materials should be designed for all types of learners, and learning styles, not just reflect the tutor's style of teaching (Felder, 1996). An effective way of achieving this is by using multiple media to target combination of media on the different styles of learner. There are many studies about the effectiveness of multimedia and learning styles in educational systems, but very few give an insight into why some combinations of media are more effective than others (Najjar, 1996). One theory that does provide such an insight is Dual Coding theory (Paivio, 1971, 1986).

According to Paivio's (1971, 1991; Clark and Paivio, 1991) dual coding theory, information is processed through one of two generally independent channels. One channel processes verbal information such as text and audio and the other channel processes visual information such as diagrams, animations and photographs. Paivio also advocates two different types of internal representational unit: 'imagens' for mental images and 'logogens' for verbal entities. Logogens are organized in terms of associations and hierarchies while imagens are organized in terms of part-whole relationships. Three types of internal processing are identified: representational - the direct activation of verbal or non-verbal representations; referential - the activation of the verbal system by the nonverbal system or vice-versa; and associated processing - the activation of related presentations within the same verbal or nonverbal system. Whilst it is agreed that a given task may require any or all of the three kinds of processing, it is not clear what and in which order people with different learning styles activate these types of processing. Furthermore, the effect on the learning outcomes of students with different learning styles is not clear when different media combinations are used.

Studies by Paivio and others (Baggett, 1989; Kozma, 1991) suggest that by choosing an appropriate combination of media, learning outcomes can be improved. For example, information that uses verbal and relevant visual illustrations will likely be learned better than information that uses text alone, audio alone, a combination of text and audio, or illustrations alone. Since 1971, dual coding theory has been used as an explanation for the effects of multimedia information on learning in a number of studies (Baggett, 1989; Kozma, 1991; Moreno and Mayer, 2000; Paivio, 1971). Many researchers agree that dual coding theory gives a reasonable explanation for the results of a large number of studies of multimedia learning (Najjar, 1996). The theory is particular useful because it gives an explanation for the way information is processed by human beings and relates this to visual and verbal styles of learning. A number of principles and guidelines for designing multimedia have since been derived from dual coding theory and applied to the development of computer-based learning materials. What is more, this theory seems to be as relevant today as it was some 30 years ago, in spite the advancements in new technology and changes in education (Paivio, 1991; Sadoski and Pavio, 2001).

Even after 30 years, there exist alternative views of memory storage that go against dual coding theory, such as propositional theory (Rieber, 1994). Propositional theorists argue that a transformation takes place of
visual information into a semantic form of storage in long-term memory. The propositional theory disputes the superiority of pictures over words because people process and rehearse pictures more fully than words. Paivio (1991), however, still believes that the evidence shows that dual coding theory has more than held its own relative to the propositional alternative and that other new theories such as the computational theory "connectionism" remain to be demonstrated.

Although much work has been done to date, more studies are needed to ascertain the effects of multimedia information on learning by students with different learning styles. It has long been acknowledged that dual coding theory can be used to study the effects of visual and verbal learners. However, little is known about the effects of multimedia information on learning by students with other learning styles, such as sensing, intuitive, sequential, global, active, and reflective styles.

One of the aims of the study described in this paper was to ascertain the effects of using multimedia information on learning by sensing and intuitive learners, as well as others, as compared to visual and verbal learners. The purpose of the study was to answer the following questions:

- Can different media combinations improve students' understanding?
- Do scores differ between learning styles for different media combinations?

This area of research was identified as being of particular importance to researchers and authors of multimedia in providing them the necessary background to help select an appropriate combination of media for designing computer-based learning materials that are appropriate for all learning styles.

**Experimental Study**

To ascertain the effects of using multimedia information on learning by sensing and intuitive learners, three different versions of learning material were presented to three groups of students. One group was shown a version of the presentation containing text and diagrams, a second group was shown a version containing text only and a third group was given a version containing sound and diagrams. Data collected from each group were then compared. The remainder of this section provides further details of the presentation, the group characteristics, and the instruments and the methodology used in the experiment.

**Presentation**

A learning module, 12 minutes in duration, was developed in order to help assess the effectiveness of different combinations of media (see Figure 1).

The Null Hypothesis and Testing its Validity

Figure 1: Screen shot of the module on statistics.

The module was developed using Macromedia Flash 5 and was about the topic of the use of statistics in experimental evaluation. The subject area of statistics was selected because it was felt that most students would have little previous knowledge about this topic and those students that did have previous knowledge
about it often found the topic difficult. The aims and objectives of the module were defined and used to produce a series of 'messages'. These messages represented key points that a student needed to learn from the module. The messages were then represented and replicated in a textual, visual and audio form. Three copies of the module were then produced as presentations. Presentation 1 presented the topic using text and diagrams, Presentation 2 using text only and Presentation 3 using sound and diagrams. To ensure that only the media combinations changed, the three presentations ran for the same length of time. Each presentation was then published in an executable form and each was placed on a different but comparable laptop.

Group Characteristics

Forty-four students participated in the study. The participants were from the courses Computing and Management and Computer Science at Loughborough University. The study was carried out as part of a module on Human Computer Interaction, which the participants were taking. In the three groups, there were 13, 14 and 17 participants, respectively. The age of the participants ranged from 20 to 24. The three groups of participants were selected according to their learning style. This criterion was implemented to assure a similar number of participants with the same type of learning style were present in each group.

Instruments

The test instruments employed in this study were a pre-test questionnaire, a revised version of the Felder-Silverman Learning Style Model inventory on learning styles (by Richard M. Felder and Barbara A. Solomon), and a post-test questionnaire. The pre-test questionnaire obtained the participants' familiarity with the statistical terms 'the null hypothesis' and 'significance' using 'yes/no' questions.

The learning style inventory consisted of 44 questions about a learner's preferred way of learning and a score sheet for calculating a learner's preferred style. The inventory chosen was selected after reviewing numerous different inventories that are available in electronic and/or paper form. We discounted inventories that: (a) would have taken too long to complete in a classroom situation; (b) were aimed at children (i.e. pre-sixteen); (c) were specifically related to visual, auditory, and tactile, since we decided these will reveal little new information or interest to us in general; and (d) were difficult to fill in and could easily be skewed by erroneous answers. The Felder-Silverman Learning Model was used for a number of reasons. It did not contravene the criteria given above and the inventory has been tested and validated, and shown to produce reliable results (Felder, 1996).

The post-test questionnaire consisted of 10 questions on a single doubled-sided piece of A4 paper. The questions were about the learning material contained in the presentation. For each question there was also a field asking participants to identify whether they knew the answer before seeing the presentation, whether the presentation helped them to recall the answer, or whether they had not known the answer before seeing the presentation.

Methodology

All three groups were tested simultaneously in different locations. The aims of the study were explained to the students, taking care not to give away details about the content of the presentations and the expected result. A handout was then given to each student containing the learning style inventory and score sheet. Students were asked to complete the inventory. Instructions were then given to the students about how to complete the score sheet. Afterwards, the students were asked to focus on the score for the learning style category sensing and intuitive learners. This category of learning styles was chosen because the class contained a broad spread of styles. In contrast, the category of visual and verbal learning styles was not selected because the population was predominantly visual. Those subjects who were predominantly sensing learners were equally divided into three groups. Subjects who were predominantly intuitive learners were also equally divided into three groups and each assigned to one of the three sensing groups. Finally, subjects who had a balanced style of learning (neither being predominantly sensing nor intuitive) were equally divided into three groups and each assigned to one of the three 'sensing/intuitive' groups. This resulted in three groups consisting of a random selection of subjects containing a similar number of learning styles. Each group was then placed in a separate
room where they were given one of the presentations. The first group was given the presentation containing text and diagrams, the second group was given the presentation containing text only, and a final group was given the presentation containing audio and diagrams. The audio in the third group consisted of a voiceover that spoke the text given in the first two groups.

Each presentation was presented using a laptop and a data projector. After each group had watched their particular presentation, they were given the post-test questionnaire to complete. Each participant’s completed post-test questionnaire was then stapled to his or her learning style inventory and score sheet. This assured that we could compare the scores of those participants with different learning styles. All the learning inventories, score sheets and post-test questionnaires were then collected within the groups.

Having collected the data, the results were then analyzed using a 2 X 3 ANOVA test to identify whether there was a difference in the participants’ scores of each group. Further analysis was also carried out to ascertain the effects of multimedia information on learning regarding each of the different learning styles.

Results

As part of the pre-test, participants in the study confirmed whether they knew what the statistical terms ‘a null hypothesis’ and ‘significance’ meant. 53.8% of the text and diagrams group, 14.3% of the text only group and 29.4% of the audio and diagrams group indicated that they knew what a ‘null hypothesis’ was. Similarly, 61.5% of the text and diagrams group, 35.7% of the text only group and 35.3% of the audio and diagrams group indicated that they knew what ‘significance’ was. These scores are shown in the bar charts in Figure 2. In the overall sample, the majority of participants had no prior knowledge of these statistical terms.

Figure 2: Comparison of prior knowledge with final scores.

Figure 2 also shows each group’s post-test mean score after seeing a presentation. Participants who were shown the presentation containing sound and diagrams tended to score the highest marks followed by participants who were shown the presentation containing text only. Participants who were shown the presentation containing text and diagrams tended to score the lowest marks in the study. Interestingly, the text and diagrams group had reported a higher level of familiarity with the subject area than the other two groups (see above), so we would have expected them to do better in the test.

Statistically, overall there was no significant difference between the scores of sensing learners, intuitive learners and balanced learners. However, although not statistically significant, ‘sensors’ did seem to score higher marks than ‘intuitors’. Moreover, as also suggested in the literature on learning theory ‘balanced’ learners did seem to score the highest marks. The findings seem to support the literature on learning theory that no single learning style is better than another, but balanced learners do seem to perform better overall.

Scores differ between learning styles for different media combinations. For some learning styles, the difference in scores is more evident. In fact, when learning style pairs are compared, one of the two is always
more affected by the change in media, than the other. With the sensing-intuitive pair, there is a statistically
significant difference in 'intuitor' scores between each media combination group, but not for the 'sensor'
scores. 'Intuitors' noticeably scored the highest marks when shown learning material containing sound and
diagrams and performed worst when shown learning material containing text and diagrams. This trend was also
true of other learning style pairs and can be seen in Figure 3.

![Graph of learning styles](image)

*Figure 3: A comparison of learning styles.*

'Global' learners tended to be more affected by media combinations than did 'sequential' learners
(sequential -global pair). In the reflective-active pair, ‘reflective’ learners performed much worse with text and
diagrams, than with audio and diagrams and with text only. However, the ‘active’ learners had closer scores for
text only and text and diagrams, but performed much better with audio and diagrams.

**Discussion**

The results from this study offer two main findings. Firstly, different combinations of media, used to
present learning materials to students, lead to significant differences in their understanding. Secondly,
participants with different learning styles perform differently for different combinations of media. These
findings support some of the ideas associated with dual coding theory. Our findings suggest that when
information is represented by a verbal and visual combination people recall more items than when using text
alone. However, the findings in our study also show that there are cases when a verbal and visual combination
can cause people to recall fewer items than when using text alone (in our case text and diagrams). A reason for
this might be the way that the text and diagrams were integrated. As a result, students may have been
experiencing split-attention effect, an effect covered in cognitive load theory (Sweller et al, 1998).

Whilst our findings suggest that participants with some learning styles score higher than others
between each group, this may be because people with particular learning styles are more suited to a type of
media. For example, the presentations may have appealed more to sensing learners than intuitive learners
because, as dual coding theory suggests, concrete nouns are better remembered than adjectives or abstract
nouns. Sensing learner tend to prefer this type of information, whereas, intuitive learners tend to prefer to
discover possible connections and relationships. As a result, intuitive learners may not have had the time to
activate their preferred types of processing. Of course, another reason may have been because, more sensing
learners were using a surface learning strategy and intuitive learners a deep learning strategy (Entwistle, 1997).

A difference in what and which order the students activated types of processing may also account for
why participants’ scores of some learning styles increased more than others between each group. Since dual
coding supports the idea that people learn by connecting new knowledge to prior knowledge, intuitive learners
may have been able to exploit this when sound and diagrams were used because time was freed up using this
A combination of media. Media synchronization may also have been a factor when comparing the difference in participants’ scores between text and diagrams and sound and diagrams because dual coding helps learners to increase interconnections to information already in memory (Baggett, 1989).

A possible explanation as to why the scores of most learners were significantly different between each group is probably the result of the redundancy effect, the split-attention effect and the modality effect associated with cognitive load theory (Sweller et al, 1998).

It is clear that more research is needed to investigate whether there is a relationship between the effects on learning and on different types of learning style and media combinations. At this stage, it is unclear whether similar results would have been obtained given that participants had been divided into groups based on a different learning style category. Further investigation is required to understand why those subjects with previous knowledge about the topic in text and diagrams group were unable to exploit this. More research is also needed to investigate whether special groups of learners with a particular style of learning (such as dyslexics) conform not only to dual coding theory but also to our overall findings. These investigations will help to understand the complex relationship between learning tasks and media combinations. From our research, we intend producing guidelines to help developers of computer-based learning materials and develop an approach for developing Adaptive User Interfaces that change according to style and media combination.

Conclusions

This study of using media combinations to deliver learning materials has produced findings that not only support dual coding theory, but also suggest that students' understanding seems to improve the most when using sound and diagrams to present the learning materials. Furthermore, students' understanding seems to improve for some learning styles more than others. We have learned that the affects of dual coding theory are more influential towards learning styles and in delivery of learning materials than previously thought. These results seem to provide tentative evidence that the media combination used to present learning materials is just as important as the style of learning adopted by the student. If the combination of media is inappropriate, it does not matter which learning style a student adopts. Students will still not perform to their full potential. This finding is particularly pertinent given that more attention is often given by tutors to the way learning materials are taught and not to the types of media used. The use of dual coding theory as an approach to accessing the effectiveness of learning materials is still as relevant today with web-based and mobile learning environments. Further research is needed to determine how some learning styles come to be affected more than others when using different combinations of media.

Non-traditional Students Learning in a Non-traditional Environment

Students 24 years of age or older learning in a college setting with new technologies

The learning styles of undergraduate students vary a great deal. Technology is often used to address a myriad of learning needs. However, as non-traditional college students (24 years of age or older) enter the university setting, technology is often a hindrance to their success. The instructor and the non-traditional student must address not only the learning style issue, but also the challenge of learning with technology developed since their last formal educational experiences. The combination of unique learning styles and lack of technology skills presents an additional challenge for these students. As instructors design their courses to include a variety of media tools, specific measures can be taken to keep the non-traditional students abreast of the class. The session will focus on the unique learning of non-traditional undergraduates and a process for applying specific media tools to the instructional components of the university classroom.

Background

What started as a Cherokee Female Seminary in 1887 is known today as Northeastern State University (NSU), the second oldest institution of higher learning west of the Mississippi River. Since its inception, NSU has evolved into one of the leading regional institutions of higher education in Oklahoma, rich in the American Indian heritage of years past and strong in the changing world of technology today. The mission of the University is to provide undergraduate and graduate education leading to 64 bachelor’s degrees, 14 masters’ degrees in selected areas and a doctoral degree in Optometry.

Northeastern State University currently has an undergraduate student population of 8,378. While the average age of a traditional college undergraduate is between eighteen and twenty-three years old, the average age of a Northeastern State University undergraduate student is twenty-seven. The majority of students attending Northeastern State University bring new challenges to the campus and in turn to the classroom. One of the most ominous challenges these students and their instructors face is the application of technology to the learning process.

Problem

The vast majority of traditional students in the Northeastern State University classrooms have been exposed to the use of current technology throughout their educational experience. These students are comfortable with the computer, Internet and multimedia software used by the instructor in the classroom. Furthermore, traditional students, by in large, use technology in their learning process. This natural extension of the learning environment assists students in successfully attaining the learning goals of the college classroom.

Each semester, Northeastern’s College of Education offers a course entitled, Technology in Education. Through this course, teacher candidates learn appropriate application of technology to the teaching and learning process. Successful completion of this course is required for all education majors. Nontraditional students enroll in the course as well as traditional undergraduates. The instructor of this course conducted action research to investigate two questions. The first question to be addressed: What is the nontraditional students’ perspective of the challenges technology presents in their learning process? The second question: What resources, digital, analog and human, could assist nontraditional students in accommodating digital resources for learning?

Method

During the Fall 2001 and Spring 2002 semester, the instructor invited students from six sections of the Technology in Education course to participate in the action research. Information concerning student age, gender and computer anxiety level was collected using the Computer Anxiety Index (CAIN). The CAIN was administered to the students at the beginning of the course and again at the end of the course in order to measure the reduction or increase in computer anxiety. Students also maintained a journal of reflections completed at the conclusion of each major technology assignment. The assignments introduced various digital and/or multimedia applications for learning. These tools included PowerPoint presentations, web page construction, Internet scavenger hunts and focused searches and WebQuest construction. The CAIN and the reflective journals contributed information to determine the answer to each research question.
Application

Although the study is action research, the findings could be applied to the wider population of nontraditional students attending regional universities. The digital and multimedia applications can be adjusted to accommodate other content areas outside teacher education. Instructors in other university settings can easily duplicate the introduction of these tools and the support model developed through the process.

Results

The month of December marks the midpoint of the action research. A combined total (traditional and non-traditional students) of forty-seven students participated in the study. The journal entries and CAIN scores are collected. The remaining data will be collected during the Spring 2002 semester. At this time, all data collected throughout the CAIN will be analyzed using a statistical software package. The reflected journals will be compiled and presented in a concise manner.

References

Abstract: This paper discusses the results of a study that compared two different course delivery methods. One of these used the Internet exclusively for module delivery while the other used a traditional campus setting. The two delivery methods were compared in order to determine if the Internet method was as good as the traditional approach. Results and suggestions for further study are described and some of the concerns identified are discussed. The module, which prepares students to take and pass an industry-recognised certification test, is currently being offered at the Community College of Southern Nevada.

Introduction

The Community College of Southern Nevada (CCSN) is responsible for delivering educational opportunities to a 45,000 square mile area in Southern Nevada. Enrolment at CCSN was approximately 40,000 students for the Autumn semester 2001 (September through December 2001). In order to meet the needs of so many students, CCSN has built six major and over a dozen outreach campuses. Despite this, many students, are still not able to take classes due to working schedules or because they reside at a significant distance from one of the campuses.

A continuing option for students who are unable to attend normal classroom instruction has always been distance education (DE). The increased availability and power of computers has created distance education opportunities that were not available years ago. However, the use of these is often sporadic, if they are used at all due to many factors including the cost of entry for both the institution (Matthews, 1999; Chambers, 1999; Barley, 1999) and for students (Matthews, 1999; Barley, 1999; Blumenstyk and McCollum, 1999). Many of the distance education modules at CCSN are delivered in a manner that requires students and instructors to meet at specific times for discussion, interaction and presentation. These modules offer students the opportunity to study in ways that are independent of place and time; indeed time and place flexibility are the two greatest advantages of distance education (Shave, 1998; Fender, 1999; Alexander, 1999). This is an attractive proposition for students with unusual or irregular work schedules or other time conflicts. This is especially the case for many people in the Las Vegas area due to the twenty-four hour nature of the entertainment industry.
An additional constraint is the lack of experience and knowledge that instructors may have (Shave, 1998; Mudge, 1999; Twigg, 2001). Technology improvements alone do not offer most instructors the ability to offer distance education modules unless they are familiar and comfortable with the technology (Shave, 1999; Alexander, 1999; Matthews, 1999; Carnevale, 1999; Trinkle, 1999; Grill, 1999; Mudge, 1999). In addition, instructors must have the time and patience to learn how to use the technology. This can include expanding the frame of reference an instructor has from classroom-based instruction to instruction that is independent of place and time. Many instructors find this difficult. The steep learning curve experienced by instructors can be partially alleviated by a good computer support department at the college or university. However, the use of outside developers or content providers can affect a faculty member’s control over his or her intellectual property.

Delivery that is independent of time requires the creation of online courses that can be accessed at any time and place, as long as Internet access is available. The module selected for delivery using the two methods described above was Computer and Information Technology (CIT) 106B. This module is a preparatory course for students who are preparing to take the Computing Technology Industry Association’s (CompTIA) A+ Core certification test. This test is one of two tests required to become an A+ Certified PC Technician. Both delivery methods used the same textbook and tests.

In order for the Internet module to be as close as possible to the actual on-campus presentation, streaming audio and video were used to transmit the classroom lectures over the Internet (Beckstrand, Barker and van Schalk, 2001). Streaming does not require files to be downloaded before use. The use of streaming technology does not require specific class meeting times. Support, independent of time and place, was offered using email, voice mail, conventional mail, and office visits. All tests and questionnaires were delivered through computers using WebCT.

**System overview**

Any module that is delivered through distance education has three pre-requisites. First, the learning material that is covered needs to be disseminated. Second, communication between the instructor and student for questions and other feedback needs to be set up. Finally, learning must be evaluated and assessed. CCSN adopted a Web development tool set called WebCT. WebCT provides Internet-based tools for testing. While there is a learning curve associated with using WebCT, the curve is similar to that experienced when learning to use a new word processing program instead of a programming language. Once the tests are in place, students can receive immediate feedback after a test has been submitted for grading.

A Web site was developed to provide communication between the instructor and students. The Web site could be used to post messages of concern for all students as well as contain an email link so that students could send the instructor an email during the delivery of the module. Additional information could be added to the Web site if needed. Students’ learning was evaluated and assessed through four tests administered on demand through WebCT. The first three tests were not comprehensive. The fourth test was comprehensive with questions covering all of the learning material presented. The Web site (http://itcert.ccsn.net) contained module syllabi, course information, textbook listings, and certification testing information.

**Evaluation**

An evaluation of the Internet delivery of the module, compared to the on-campus delivery, was conducted. This section describes the analysis plan and the results obtained.

The Computer Literacy Questionnaire (CLQ) (Murphy, Coover, and Owen, 1989) was administered to investigate any differences between the groups and as a possible predictor of students' performance. The first four questions on the CLQ collected demographic information. The thirty-seven literacy questions of the CLQ assessed self-perceived computer literacy. The scoring of the questionnaire was based on a five-point scale. Lower scores indicate less familiarity with computers while higher scores indicate more experience.
Analysis plan

The analysis of the study results consisted of four parts. The first part sought to discover if there were any differences between the Internet modules offered during the Summer time-frame and the module offered during the Autumn time-frame. Any major differences in the modules would prevent the combination of the groups into a single unit for comparison with students enrolled in the on-campus module. The second part of the analysis checked for any initial differences between students on the Internet module and students on the on-campus module that might have affected the outcomes and conclusions. The third part of the analysis involved the actual comparison of the on-campus module and the Internet modules. The results were expected to support the hypothesis of no (statistically significant) differences between the module outcomes. This would indicate that if an online module was designed correctly, students should be able to achieve the same results taking the online module as those taking the on-campus module. Finally, regression analysis was conducted in order to uncover factors that explain students' performance.

Data analysis was performed using SPSS for Windows (version 8). Students' names were not recorded in the data files. Students who registered and paid for the module were monitored to measure attrition. A total of 91 students were registered for the three Internet deliveries. Comparisons between the different presentation methods included age, pre-test, other tests, questionnaires, attrition, and final grade.

Results

All students responding on the CLQ indicated that they owned and used a personal computer.

Students enrolled on the Summer Internet delivery and Autumn Internet delivery did not have any statistically significant differences in the areas evaluated that precluded them from being combined as one unit. More Summer students registered for the Internet module because it was the only offering of the module and they did not want to wait until Autumn. Overall motivation concerning the modules was very similar between the two student groups. Since the results indicated that the two groups were similar, they were treated as one group in comparisons with the traditional module presented in the Autumn.

The analysis of the pre-test scores indicated that both groups were starting at an equivalent knowledge level. It was observed that the Internet module was the first non-traditional module for many of the enrolled students. However, as might be expected, most students following the on-campus delivery had previously taken other on-campus modules. Each of the tests administered during the module delivery was compared for differences. Questionnaire responses were also compared for changes during the delivery time frame. It was found that students registered for the delivery method they desired.

A number of different measurements were used to determine if the research hypothesis identified above was supported. Questionnaire One measured students' attitudes concerning motivation, delivery method motivation, and collected some demographic information. Questionnaires Two and Three measured students' attitudes concerning motivation, delivery method motivation and module delivery evaluation. Students' attitudes remained consistent during the module delivery with little difference between the two groups. A 2 x 4 mixed measures ANOVA showed there were no differences in test performance between the two delivery methods over time; the pattern of differences between the scores on the four tests was the same for both delivery methods. The test results thus supported the hypothesis stated above.

Regression analysis showed that students' test performance on test 1 was not related to their performance on the pre-test. Test performance on test 2 was significantly related to performance on the pre-test and test 1 combined, where performance on test 1 was a significant predictor. On test 3, performance was significantly related to performance on all previous tests combined, and performance on test 2 was a significant predictor. Test performance on the final test was significantly related to performance on all previous tests combined, with performance on test 3 and the pre-test being significant predictors.

Overall, the results indicated that students in the two delivery types were more similar than dissimilar. This conclusion was supported by the results of the first three steps of the data analysis. Even the attrition rate
between the two delivery methods was not significantly different. Detailed results will be presented at the conference.

Lessons Learned and Emerging Guidelines

The study results support the stated hypothesis. The Internet module was comparable to the on-campus module in helping students attain results. The students in the groups were very similar in all areas of comparison, in spite of the lack of random assignment to the different delivery methods. Any differences identified were not major and did not influence the outcome. This study supports the developmental path used to facilitate the Internet delivery of the module. By using a known and established module, as well as the same support material, a successful non-traditional version of the module was created.

The study does identify some issues that need to be addressed. The attrition rate of both delivery methods is a concern. Additional study should be considered to identify the reason why many students began the module but then left before completing the work. Another issue is the large number of students that completed the modules but received fail grades. This is especially important for two reasons. First, CIT 106B is an introductory module for new and beginning students. Second, CIT 106B is an elective for many other study programmes in the CIT department. Failure in this module could have a negative effect on new students at the college and on students completing programmes of study.

The high attrition and large number of fail grades could be attributed to students' self-assessed levels of knowledge of computers and technology indicated by the CLQ results. Two-thirds of the students who responded on the CLQ scored in the novice range. The CIT 106B module is totally about computer technology. Identifying ways to help students develop basic computing skills prior to taking the module might help lower the high attrition and reduce the number of fail grades.

The CIT 106B module, developed using the above methodology can be viewed at http://webcampus.ccsn.nevada.edu. Select the "Logon to MyWebCT" option. The sample ID is student and the password is temp. All lectures will be available, but due to academic constraints, the module tests will not be available. The account above will be active during the EDMEDIA 2002 conference.

Conclusions

The use of Internet technology, along with various tools can make truly independent learning a reality. The offering of a module with time and place flexibility offers opportunities for students who otherwise would not be able to take advantage of higher education and provides as good a learning opportunity in this instance as the on-campus module. Because the module is delivered via the Internet, learning can take place at home, while travelling, or at an institutional computer lab. Such modules can also be offered by an institution to students not included in its normal audience - a global audience. This type of module is also attractive because it offers self-paced study to learners. Lectures can be repeated multiple times if a student is having difficulty grasping the subject - something that is not possible in a normal classroom environment. The advantages associated with this type of distance education module were sufficient motivation to continue the development of two similar modules. The first of the follow-on modules was made available in Spring 2001 and the second of the follow-on modules will be made available in Spring 2002.

Not all disciplines will be able to use this type of distance education module. However, the ability to offer such modules provides benefits both for the college (CCSN) and the students. These benefits far outweigh the negative aspects. This first module, along with the additional modules, will provide educational opportunities for students that would otherwise not be able to enjoy the fruits of higher education.

Cooperative Learning: Assessment of Team-work

Karen Belfer
Technical University of British Columbia
karen.belfer@techbc.ca

Ron Wakkary
Technical University of British Columbia
ron.wakkary@techbc.ca

Abstract: This paper examines the benefits and challenges of for an institution to support cooperative learning through assessment. The paper will focus on the key issues behind the design and management of teamwork assessment, and the development of guidelines to undertake the implementation of an institution-wide approach to cooperative learning.

1.0 Introduction
The main objective of cooperative learning is for learners to collaborate and use others as a resource, for sharing knowledge, “challenge other and their own views, hence to serve as a source of puzzlement that stimulates new learning” (VonGlaserfeld, 1989); yet stand separately for individual assessment.

In many cases the complexity or purpose of the task extend to include assessment, as part of the cooperative work. Therefore the need to develop different methods that explain ‘how’ to calculate individual marks from group marks (Lejk and Wyvill 1996; Brown, 1995).

But the true effectiveness of the assessment of cooperative work doesn’t lay in the method, but in the goals, behind its design and implementation.

2.0 The Need for Collaborative Learning
Cooperative learning is among most effective learning method in higher education (Astin, 1993; Johnson, et al., 1991; CELT, 1995). It became the central strategy to learning at the Technical University of British Columbia (TechBC).

Critically, TechBC embedded the goals of: learning effectiveness, learner centeredness, responsiveness to workplace needs, and effective use of educational technology, at an institutional and cross-program level. The adoption of cooperative learning supported and interwove these goals very effectively.

How do you translate all the benefits of cooperative learning into an active every day working and learning environment that thrives across programs, schools, levels, instructors, diverse learners, cultures, and subject areas?

To date, research has dealt with common problems of cooperative learning at the course level, but many of the issues that were encountered at TechBC, are institution-wide problems, such as managing team activities across courses, team dynamics, and extending the cooperative work all the way to team assessment.

5.0 Results
At TechBC, we developed an approach that takes into account the values of cooperative learning and a framework that supports good instructional design, providing developers and instructors with guidelines that enforce sound team assessment practices.

In the following segments we describe why we considered instructional design, the principles of cooperative learning, peer and self-assessment and the assessment of learning best practices to be the core elements to be addressed in the development of our team assessment guidelines.

5.1 Instructional Design
Instructional design is a systematic approach to curriculum and course development that focuses on learning objectives as a means for the development of learning experiences.

The learning objectives communicate the knowledge and skills learners can expect as outcomes of the completed unit of study. They should be adopted as the basis for the design of assessment and feedback techniques and seen as an inherent part of the educational structure.
5.2 Principles of Cooperative Learning

The method of collaboration in the learning environment is for learners to work together in groups and individually assessed (Slavin, 1995).

The purpose behind cooperative learning is to design activities that motivate learners to work with each other, because they see the value of others views and sharing of knowledge, but also because the learning of their peers is important to them (Slavin, 1995a). It is in the course of this interaction that all group members’ benefit, and it is through individual assessment that the value is measured.

However it is also often to see some examples in which the group activity is designed in a way that group cooperation and the assessment are linked together. It's when learning activities are translated into assessment activities (in which marks or grades are assigned); that learners start to worry about the effect that the actions of others will have on their marks.

There are five essential elements that make cooperative learning activities work: a) Positive Interdependence, b) Promoting Interaction, c) Individual Accountability, d) Team skills and e) Groups Processing. But it's Positive Interdependence and Individual Accountability that have a mayor role in the assessment of teamwork.

These two principles of cooperative learning seem so far apart, and difficult to accomplish at the same time. The success of team-based learning relies in heavily on the ability to design and activity balances both elements. There is a very fine line between collaboration and collusion (Isaacs, 2002).

Slavin (1995), describes the success of cooperative learning as the ability to have group goals but be capable of assessing individual accountability.

5.3 Peer and Self-assessment

Both peer and self-assessment methods have been widely used as variables to ensure that either or both individual accountability and positive interdependence have been achieved in team-based assessments.

Some research seem to suggest that peer and self assessment are more useful in the assessment of group processing, team skills and positive interdependence, while others suggest that it is successfully applied to assessment of individual accountability (skills and knowledge).

5.4 Assessment of Learning

"Effective learning occurs when learners come to internalize the project of learning, benefit from having meaningful assignments that develop their knowledge and skills, and receive useful feedback in order to improve performance" (Battersby, 1999). For that to happen, assessment must follow these basic principles:

- It should be clearly linked to the learning objectives.
- The benchmarks of satisfactory performance are clearly established before learner outcomes are measured.
- The assessment supports the learning process by providing clear and valuable feedback. Assessment provides data on performance for grading purposes, as well as information on the effectiveness of the instruction. (Diamond, 1998)

These principles can be attained following good instructional design practices. Assessment and learning are intrinsically related, "... the assessment methods and requirements probably have a greater influence on how and what learners learn than any other single factor" (Boud, 1995).

6.0 Conclusion

The design, development and implementation of cooperative learning can become a very complicated task, especially if the learning activities are extended to the assessment of teamwork. Specifically, critical issues of team assessment need to be addressed to achieve the effective learning, especially for the learners. Institutionally, if assessment supports the overall goals for learning, across programs, learning staff, and supporting staff, the goals are more attainable.

Hopefully, we have demonstrated the need, challenges, and the benefits of developing assessment guidelines for cooperative learning support the goals of a new and innovative university.

Kids Can Care About Cyberethics!

Dr. Mary Ann Bell
Department of Library Science
Sam Houston State University
United States
mbell@main.com

Abstract This paper is a discussion of the importance of teaching cyberethics to K-12 students. It includes the results of two informal surveys: one of teachers and librarians regarding their experiences with cyberethics instruction, and one of students regarding their knowledge of cyberethics. A description of a school-wide project to emphasize cyberethics through a web collection of student created clip art is also included.

Introduction

Computer ethics, or cyberethics, is an area of technology education that is frequently neglected by teachers, librarians, and administrators. Students are using computers in ever-growing numbers, but in many schools are receiving little or no guidance about the issues relating to ethical use of technology. Defining cyberethics, whether for adults or for students, is a bit daunting because the term covers a multi-faceted array of issues, including at least the following: respect for intellectual property, respect for privacy, and hacking. Indeed one expert, Dr. Marvin Berkowitz, has included seven specific issues: computer hacking, copyright issues, hate speech, privacy, computer addiction, plagiarism, and personal identity.

Discussion

Part of the reason why students are not being offered information about cyberethics is because the adults who should be leading the way are themselves uninformed. Many publications, workshops, and technology courses do present information to educators about cyberethics. Unfortunately, as with other areas of professional development, too often people do not receive training due to lack of time, lack of access to workshops or seminars, or lack of awareness of these issues. Teachers and librarians must become informed leaders in this arena before they can help students to make changes.

Recently, I explored the issue of cyberethics and its emphasis in schools through an informal survey of teachers and librarians. The survey was directed to members of LM_Net and EDTECH discussion groups, and also to library science students. I posed questions about how ethical issues were handled with teachers and staff, and also about how these issues were addressed with students at their schools. I received thirty-four responses, with equal representation from librarians and classroom teachers.

I asked eight questions about the ways in which cyberethics was addressed on campuses with faculty and staff:

- Who is the voice for copyright and/or respect for intellectual property on your campus? A three to one ratio of responses pointed to the librarian or media specialist as the responsible spokesman. One notable exception was an individual who reported that her district had a specific position, Copyright Compliance Officer, who monitored copyright issues and situations. That administrator then directed training to librarians, who served as campus liaisons. Other comments about the role of librarian as champion of copyright included, "If anyone is going to do this, it will be me, the librarian."
- Are copyright notices posted on your campuses? Less than half of the respondents said yes, with the majority indicating notices were posted on or near photocopy machines. Unfortunately, this simple step does seem to be neglected in a number of schools.
- Who is the voice on your campus for protection of computer software? Responses to this question were evenly split between the librarian and the campus technology teacher or
specialist. Only two individuals indicated a direct knowledge of a district wide emphasis on compliance in this area. Many people said the issue was not addressed at all at their schools.

- How widespread is the violation of software copyright by teachers and staff on your campus? Almost all respondents reported that it was their impression that copyright was respected in most cases. Several people reported campus guidelines and policies. As one computer teacher commented, "The fines for piracy are well known here." Another technology teacher offered a somewhat jaded comment, "I would not think it is very much as our school has provided the necessary software for its teachers. If the software is not provided, teachers will violate copyright laws." Many respondents were unaware of what measures were taken to protect software copyright in their buildings or districts.

- Who is the voice for privacy regarding technology, and is this issue taken seriously? As with the responsibility for software copyright, the vote was split between librarians and technology teachers. This is an issue that seems to elicit growing awareness and concern. Some respondents said building and district administrators supervised privacy issues. Several librarians pointed out that their automated circulation systems did not save student checkout records, thus making it easier to protect students' reading histories.

- Who speaks out against computer hacking and in what context? This issue was, in most cases, said to be under the domain of technology specialists and teachers. In many cases, respondents also mentioned the district acceptable use policy as a measure against hacking.

The second part of the survey was about how cyberethics are being taught to students, and comprised of five questions:

- Who tell students about copyright? As with informing faculty, the responsibility for telling students about copyright fell almost entirely to librarians. Most computer teachers who responded also reported that they try to include copyright in their lessons, but also named librarians as campus leaders. One librarian said she mentions copyright every time a class comes in for research during her introductory remarks.

- Who talks to students about software and copyright? Librarians and computer teachers were equally cited. However, about one third of the respondents were under the impression that it was not addressed at all on their campuses.

- Who talks to students about computer hacking as an ethical issue? For the most part, computer teachers were named as the voices for this issue. One such teacher commented, "We attempt to assuage the hackers by keeping a half step ahead of them. We don't always succeed! However, I have learned a lot from the kids when security is breached." Teachers and librarians from schools with strong acceptable use policies felt that guidance for students was enhanced by the policies, if students were sufficiently aware of them.

- Are there specific lessons taught about cyberethics on your campus? About half of the respondents said yes, but not necessarily to all students. Usually the lessons were offered in computer classes. The remainder said such lessons were not offered at all. Some of those who said yes mentioned state computer competency tests, which target these issues along with other computer skills, as the impetus for instruction in cyberethics.

- The final question was: In general, is your campus really pushing ethical issues? Responses were evenly split, with half saying the issues were truly emphasized and the other half saying not at all. Some were emphatic in stating that the issues were neglected. One respondent said, "Not enough time. Just trying to teach the basic subjects is the problem." Another said, "Mostly no. It is not a subject that fits into class lessons or requirements." On the other hand, a computer teacher reported, "At this point we are stressing the responsibility of the staff member. In a faculty meeting the media specialist goes over both our acceptable use policy and copyright policy every school year." There were indications from several people of a growing sense of need for instruction about cyberethics. As one reported, "This year one of our goals is to raise awareness through improved signage, reminders to staff, and workshops with students." Another said, "It is difficult to find the staff and time to cover everything that needs to be discussed, but we are making an effort."

What conclusions can be drawn from this informal survey? Several points came to mind as I reviewed the responses:

166
First, I did not receive a single submission where the respondent thought that enough was being done at his or her school to address cyberethics. Everyone reported room for improvement. As computer use becomes more universal and pervasive, the need for adequate training about cyberethics will surely increase.

Librarians are presently front and center in efforts to inform faculty and students about cyberethics, and this will continue to be the case. The general consensus from respondents was that if anyone on their campus were going to speak out on such issues, it would be the librarian.

One thing that could be done easily and quickly would be to post signs with copyright guidelines near copy machines, computers, software shelving, and audiovisual equipment storage areas. This beginning step can provide initial awareness of the issue with other initiatives to follow.

An AUP (Acceptable Use Policy) is an important first step in promoting ethical computer use, but it is not a solution in and of itself. Many respondents indicated that, while their schools had such documents, awareness on the part of students, parents, and faculty was not widespread.

While instruction about cyberethics may be lacking, there is a growing awareness and concern. In the near future, librarians and teachers will need to address these issues with both faculty and students if they are not already doing so.

Librarians are in an excellent position to be leaders in promoting cyberethics because they work with staff and students, because they assist with research, and because they are often leaders in technology on their campuses. Training and informing teachers and staff should be offered through a variety of means, such as: in-service, web presence, handouts, one-on-one contacts, and any other creative means which can be developed. Often it is best to concentrate on one issue at a time when launching efforts to inform people about cyberethics, to avoid overwhelming them with information and guidelines. The emphasis should be on positive reasons to respect the issues rather than negativism or scare tactics. Once teachers on a campus begin to gain awareness, they can plan lessons to share the information with their students.

What are some effective ways to teach students about ethical computer use? As with adults, students will do best if they are not presented with an overwhelming amount of information all at once. After a general discussion, it is probably wise to present one issue at a time and explain each one simply and clearly. Students are even less apt than adults to respond to stern admonishing rhetoric. While it may be true, for instance, that stealing ideas or words is as bad as stealing merchandise from a store, lecturing students along these lines is likely to be poorly received and counter-productive. Teachers should explain each concept thoroughly, making it clear exactly what rights students do have and offering positive reasons for behaving ethically. This approach is much more likely to succeed in gaining students' attention and compliance. Students may be informed of the negative consequences of violating ethical guidelines, of course, but the information should be accurate and not couched in overly threatening tones.

Usually a school or district will have an Acceptable Use Policy (AUP) that addresses ethical issues for its students and staff. Unfortunately, in many cases, students and faculty are not thoroughly informed about their policy and may even be unaware of its existence. Making sure they get this basic information is one way to begin discussing cyberethics. Then the various sub topics can be addressed one at a time. One Texas school district, Conroe Independent School District, developed a test for students over the Acceptable Use Policy. The test was put into place as a requirement before students could gain permission to use the Internet. Teachers and staff were also required to pass the same test and answer additional questions about their responsibilities in order to get computer accounts. This tactic required everyone to have at least a basic awareness of district policies and gave teachers a starting point for instruction. The tests were made available online via the district web pages, to be taken online with the resulting passing scores stored in a database so that teachers could check, if necessary, to verify whether a student has passed. If such a requirement is not in place, a district Acceptable Use Policy is still an excellent springboard for discussions about cyberethics.

Another major resource to reference when discussing computer ethics with both teachers and students is the Ten Commandments of Computer Use. This widely quoted document was originated by The Computer Ethics Institute, and appears at the end of this paper. Doug Johnson, Director of Technology, Mankato Public Schools, Mankato, MN, has further synthesized ethical concepts into his "3 P's of Technology Ethics:

1. Privacy—I will protect my privacy and respect the privacy of others.
By the end of class discussion, they were thinking about ideas for images to create. They brainstormed various topics for drawings such as academics, sports, animals, holidays, nature, fun, sports, to market, such as an original cartoon character that they might want to develop in the future. The class to drawings contributed to the site. Students were told not to submit anything that they might someday want to test students' awareness of the issues. Before the lesson, students were unaware of fair use and actually thought they had fewer rights to use copied words and images than they do. They were also uninformed about when and how to cite sources. The tests results and other class discussion focused on positive reasons to honor other people's work. The teacher and librarian asked students to put themselves in the place of an artist and imagine how they would feel to find their work taken, and even marketed by someone else. Respect for copyright that students seemed to accept, was that it encourages original work. If artist and imagine how they would feel to find their work taken, and even marketed by someone else. Another reason to honor copyright that students seemed to accept, was that it encourages original work. If

Before they began work, students were given a brief waiver to sign that waived their royalty rights to drawings contributed to the site. Students were told not to submit anything that they might someday want to market, such as an original cartoon character that they might want to develop in the future. The class brainstormed various topics for drawings such as academics, sports, animals, holidays, nature, fun, sports, and others. By the end of class discussion, they were thinking about ideas for images to create.
During the second class session, the students worked on clip art to contribute. The art teacher gave each student a four-inch square of white paper, and told students to fold the squares into fourths. Then she directed them to create drawings to fill each of the four one-inch squares, using colored markers, map colors, or crayons. The librarian brought in picture books to help generate ideas, but reminded students that work should be entirely original. Two areas of concern were gang related drawings and reproducing of cartoon characters not well known to the teachers. Students were reminded to avoid commonly used images in gang graffiti, and to refrain from reproducing look-alikes of popular cartoon and animated characters. Before posting any pictures, the school’s police officer reviewed images for gang connotations. Students had two class periods to work on the pictures and could work on them at home as well. The resulting products were clever and colorful. Student assistants and the librarian worked together to scan the images and post them to web pages. The only editing done to images was to remove smudges or stray marks. Otherwise, any picture accepted for use was posted without digital altering. After completing the web pages, the librarian and teachers unveiled them to the school with much fanfare and praise for the unselfish sharing and original work on the part of all participating students. Quickly images started to appear on school web pages, teacher made handouts, in the school newspaper, and in student projects. Students continued throughout that year and subsequent years to add images. During fall 2001, due to the world situation, students decided patriotic images would be an especially important category. This additional collection grew rapidly with other topics receiving additions as well, and new topics being added as needed. Students expressed pride in their clip art collection and enjoyed seeing their images used by teachers and fellow students. They also enjoyed sharing the work with their families and friends via the school web site.

During the 2001-2002 school year the librarian and computer teacher decided to expand the clip art collection and involve computer students as well as art students, and to encourage submissions of computer generated artwork. They presented much of the same information to the students as the art teacher, but because the computer teacher wanted to take the students beyond the issue of plagiarism, the quiz also covered the issues of hacking and respect for privacy. Again results showed that students were unclear on many of the issues, and the discussion that followed focused on clarifying misconceptions. Students reviewed the existing clip art collection and agreed to increase and add dimension to the collection by contributing computer created creations. They signed release forms, as had their classmates in art class, allowing their work to be shared freely. The resulting images have increased the size and variety of the collection and have encouraged participation by additional students.

Conclusion

Today's children are growing up with computers in their schools and homes. Dr. Marin Berkowitz asserts that educators should not wait until high school or even junior high to talk to students about cyberethics. He suggests that 9-12 year old children can grasp basic issues and benefit from lessons about the ethical, legal, and safety issues related to computer and Internet use. Realizing this goal involves informing educators, incorporating the issues into instruction, and making ongoing awareness an integral part of how we instruct students regarding the responsible use of technology.

Wireless Instructional Strategies in the Humanities (WISH): Training Traditional Faculty for Change

Kathleen Bennett
Innovative Technology Center
University of Tennessee
United States of America
kbennett@utk.edu

Abstract: Placing powerful technology tools in students’ hands along with activities designed to encourage collaboration, exploration, and critical thinking, causes a role shift to occur. Students become researchers and presenters, constructing knowledge and adding it to a global knowledge base. Faculty who incorporate technology into their course work then can become guides and facilitators. However, the challenges created by this role shift require a reframing of our faculty development model. The Innovative Technology Center at the University of Tennessee designed and implemented a pilot project, putting powerful, wireless laptops into student and faculty hands. The Humanities area of Arts and Sciences was chosen for this project because they are typically underserved in terms of technology resources, yet rich in opportunities for collaborative work. With laptop computers, a versatile suite of software tools, and a customized WISH institute for training before project launch, our implementation team crafted a model faculty development project that addressed key aspects of transitioning traditional faculty to a more collaborative and dynamic learning environment.

Context of the WISH Project

“To ensure that America’s students are the best-educated in the world, we have to have top-quality, innovative higher education; replicate the educational approaches that work; and take advantage of all the new technologies that can strengthen student learning” (Office of Postsecondary Education, 2001). Many voices agree that students need to emerge from their undergraduate experience equipped for the modern work environment. Employers state unequivocally that they want information-savvy, team-comfortable, and problem-solving employees. In a government report surveying the impact of IT on the American economy, the authors note that “Even for workers in non-IT jobs, basic IT skills are becoming a requirement....Educators, too, recognize the growing need for skilled workers and are designing curricula to include basic IT skills training...” (Office of Policy Development, 2001, p. 41). We must move rapidly toward creating learning environments in which students receive the skills, both cognitive and technical, which will enable them to succeed in the contemporary world. While curriculum content is the same as in a traditional classroom, the ways in which we engage students with this content need to be dramatically altered. So our team at ITC sought a way to bring technology out of the lab into the classroom and then examined one model for how to prepare faculty for new opportunities and challenges.

A pilot project involving the use of technology and collaborative methods, appeared certain to pose challenges for traditional faculty. The shift from teacher-centric to student-centric classroom does not follow a smooth path. From the inception of the project, the implementation team understood that resistance to change would appear, even among self-described innovators. This paper will describe the WISH institute as a creative vehicle for assisting faculty in transforming the classroom. The workshops of our WISH institute were designed to explore and create new strategies for delivering material and structuring classroom interactions. Our training focused on designing collaborative activities that would increase students’ engagement with the material. We looked at ways to utilize common communication tools such as email and discussion forums to leverage the power of networked laptops to enhance writing and discussion skills. At every stage of the project, we gathered faculty feedback and addressed pedagogical and technical issues as they arose.
Transformation of teaching practice in higher education requires a convergence of initiatives and the vision to identify opportunities for pedagogical research. In the WISH project, three university groups, the Network Services, ITC, and the College of Arts and Sciences, converged to allow exploration of numerous issues of critical importance today as higher education responds to the call for change in the way it educates students. The campus-wide wireless initiative was launched by the administration in the summer of 2001 and is being implemented by Network Services. The Innovative Technology Center brings together faculty development specialists, instructional designers, network and programming specialists, and graphic designers, to serve the pedagogical needs of the entire faculty. The College of Arts and Sciences, traditionally underserved in terms of access to technology, offered us access to traditional faculty who had expressed a desire to explore new pedagogical possibilities.

University Wireless Initiative

An administrative push for a wireless campus network had created the context within which the project unfolded. In the summer of 2001, The University of Tennessee was launching one of the largest 802.11b wireless initiatives in the United States based on number of access points, and the WISH project was developed concurrently. (For more information, please see http://wireless.utk.edu). This simultaneous development of initiatives, one technical and one pedagogical, added to the challenges we faced, but also offered extraordinary opportunities to observe how faculty and students function and adapt in an experimental environment. One of the first casualties of the project was the collaborative networking software, whose primary purpose was to permit the instructor to call up a student’s screen onto the laptop connected to the projector. As Network Services added security layers to the wireless rollout and as they expanded the subnets, the collaborative software proved unable to negotiate clients on a network that dynamically assigned IP addresses to individual machines. The software had functioned well in a static IP environment, but simply collapsed when dynamic host addressing was introduced. However, it had functioned long enough to allow us to see the enormous potential for true exploratory sharing. In their Final Reports, several WISH participants referenced the teaching potential of this software, so our search for that particular tool continues. A positive convergence emerged from the classroom renovation project that was occurring concurrently. Smart classrooms were being created across campus, and our participants saw a concerted University effort to provide technology-enhanced learning environments for instructors and students.

In addition, the wireless cards often experienced difficulty when they tried to connect to the network through a malfunctioning access point. Unfortunately, the task bar icon which indicated a network connect was not discriminating enough to know that the access point was not offering “access” to the Internet. The network monitoring software also gave false positive readings for these “live” but malfunctioning access points. Much frustration and confusion ensued. Trouble-shooting these early obstacles proved time-consuming for our network specialists and frustrating for the instructors who simply wanted the technology tools to work.

Innovative Technology Center

The WISH Pilot Project was framed from the very start as an exploration of how to redefine the traditional classroom in a networked environment as well as the diverse support issues surrounding the University’s wireless initiative. We invited faculty who wanted to establish innovative teaching practices and explore research possibilities related to implementing wireless computing in a classroom setting to apply for participation. We asked what the classroom might look and feel like when powerful computing potential was wedded to collaborative activities, specifically designed to challenge students to critical thinking and problem-solving. Unlike traditional grants, this call for proposals was open-ended in unusual ways. We asked for faculty willing to re-examine their traditional teaching strategies in the light of new possibilities offered by mobile, networked classrooms.

Supporting the project successfully involved a group of professionals with a wide range of expertise, a shared desire to expand definitions of teaching and learning, and a commitment to customer service. The implementation team consisted of the Director of ITC with her humanities background behind a doctorate in instructional technology, our technologies integration specialist, a web instructional technologist with a strong humanities background, and a program coordinator who handled technical
issues, group communications, and the complexities of scheduling the two carts filled with laptops. In addition, the program coordinator did in-class training on the use of the laptops and the network, thus freeing faculty to concentrate on reframing the learning environment. Brainstorming sessions had launched the project and the team met regularly to deal with the issues as they arose.

**College of Arts and Sciences**

"Deep, hands-on learning through research is commonplace in the sciences, but it is more challenging to design these experiences for students in the humanities." (Brown, 2000, p. 222). Our project was deliberately crafted to examine the pedagogy as well as the mental maps of traditional instructors whose previous access to technology-rich environments had been limited. Thirteen faculty from Modern Foreign Language and Literature, Political Science, English, History, Philosophy, Religious Studies, African-American Studies, and Human Services were chosen to participate in the project. The courses impacted ranged from "Images of Jesus" in the Department of Religious Studies to "Introductory Conversational Portuguese" in the Modern Foreign Language and Literature department. Several WISH team members possessed strong humanities backgrounds and were intrigued by the idea of developing workshops to transition traditional faculty to new ways of constructing learning experiences in a networked environment. After putting out the call for proposals to this college and establishing project parameters, we then developed the WISH Institute to frame the key issues and open the dialogue. We now faced the conceptual challenge of moving instructors from lecture and face-to-face discussion paradigm to new ways to engage their students with course material. A shift in the structure and interaction in the classroom challenges faculty in two ways: their comfort level with the technology itself and their comfort level with new ways of designing and implementing learning activities.

**Project Requirements**

The call for proposals asked about faculty willingness to innovate and to explore current pedagogy with an eye to transforming it. The call asked about current uses of technology in teaching and thoughts on potential for change. From the pool of proposals we selected only 14, based upon our ability to offer ideal support as well as upon the energy and commitment we sensed in their writing. In addition, we deliberately chose faculty with diverse skill levels. The selected faculty received a fully equipped wireless laptop, a suite of software tools, and a stipend. In return they were required to commit to the project requirements.

- Integrate wireless laptops in your course for a minimum of 1/3 of the semester.
- Participate in the WISH Summer Institute. The WISH Summer Institute will require six hours of core classes (to be held at ITC) and ten hours of individualized training (that can be defined through flexible learning opportunities). The core classes will address technical, instructor-centered, and student-centered strategies. The individualized training will focus on reshaping the curriculum and content in order to make maximum use of networked resources.
- Attend bimonthly meetings with the ITC WISH Implementation Team (WISH IT) to be held for the duration of the project.
- Conduct student assessment at the end of the Fall 2001 term. ITC will provide the basic assessment tools.
- Participate in a WISH Faculty pre- and post-project assessment.
- Submit a final report.

**WISH Institute**

The WISH Institute held in the summer of 2001 directly addressed the challenges of weaving collaboration and connectivity into the traditional classroom. After surveying participants to identify their comfort level with software, hardware, and networks, the implementation team developed three courses to address pedagogical and technical issues and prepare the foundation for our research interests. The first course, "Technical Strategies for Wireless Laptops," focused on basics of handling, maintaining, and using a laptop computer. Issues included battery charging, hooking up projectors, and mobility across campus subnets. Participants discussed multiple log-ons, the realities of shared bandwidth, and explored classroom
management issues. Laptops were stored on a “mobile” cart, but the term “mobile” was a stretch and negotiating crowded hallways and multiple floors challenged the instructors as well as the support staff. Each cart contained 16 PC laptops and one projector.

The second course focused on “Instructional Strategies for the Wireless Classroom.” The University uses Blackboard as its course management system and our Institute addressed some of the built-in tools. Participants explored strategies for maximizing use of networked resources, from managing email to receiving assignments via the digital dropbox in Blackboard. We discussed how to manage increasing numbers of email messages to designing a discussion forum topic that would engage students in dynamic, professional discourse. We examined strategies for integrating the Web into the classroom environment. We went on virtual field trips and used a web-page archiving software to capture a website to the hard drive, in case of connectivity failure. Noted one WISH participant, “I have also learned and have re-committed myself to the notion of planning back-up lessons. When working with the wireless, my thought is that three backup plans are necessary.....” (Woodside, 2001).

The final course, “Collaborative Models in the Wireless Laptop Classroom,” explored ways to group students for effective collaborative work through issue groups, triads, and collaborative writing teams. We shared possible methods for assigning students individual roles based on divisions of labor to enhance learning. Participants ventured on a “webquests about webquests,” in order to experience both the structure of a webquests and the way it felt to work collaboratively toward an end product. One of the key obstacles to faculty adopting collaborative, problem-based learning is the challenge of assessing both the process and the product, so we assembled readings and samples of assessment tools to address this potential barrier.

In addition to the six-hour WISH Institute, faculty were asked to schedule an additional ten hours of customized support, based on their curricular plans and their levels of expertise. Paul Hagner has noted that “many faculty, especially the Risk Aversives, need flesh and blood support to make their transformation.” (Hagner, 2001). The WISH implementation team provided that “flesh and blood support” to assist these instructors in transforming their teaching as well as the learning environment.

Conclusions

We had initiated an ambitious project and garnered many insights from our experiences. Our greatest insights and understandings came from carefully watching these faculty members as they moved through the experience. Our recommendations emerge from a careful examination of the project as an experiential whole. Two major categories deserve addressing, technical and teaching/learning.

In the technical arena, expect heavy support demands and meet each demand with patient attention. Always expect the unexpected. The recognition of the false positives on connectivity did not emerge until we began to deconstruct the entire project, in search of areas to address in the next iteration. In addition, we would caution that you be very selective about the software that is included in the package for faculty and students. Two critical pieces of software, the collaborative networking software as well as the networked writing environment software, did not function as advertised, causing mutual frustration all around. In addition, the critical website capture tool did not function as efficiently as we had hoped as a backup tool. Increasing faculty comfort level with these new tools is essential. Student comments at the close of the project indicated that they were keenly aware of the impact on the learning environment of a faculty’s readiness to use technology tools effectively.

In the area of teaching and learning, we recommend staying focused on pedagogy, instructional design, and multiple strategies for using the tools, even as the project seems enmeshed in technical challenges. Deliberately create community around the project and plan for its continuation. Only through rich dialogue will we move together into the future. Communicate constantly with all stakeholders, using all the tools available, from the ubiquitous email to discussion forums, to bi-monthly debriefings, and micro-teachings where successes are shared.

Success can be measured in many ways. Thanks in part to the range of faculty skill levels, we were able to note a wide range of successful learning strategies. One technically literate faculty member restructured an entire course around the wireless laptops. She comments in her final report, “I thought about why I was doing what I was doing in the classroom, right down to the last detail” (Kelly, 2001, p. 1). Another instructor used the brainstorming tool, Inspiration, for a collaborative exercise within one class. His initial, small success allowed him to be more aware of the possibilities for enhancing language learning with such tools.
As James Ellsworth notes, "When change is being driven by changes in the society around us (a suprasystem), we must be willing to rethink everything about the way you teach and learn (Ellsworth, 1997, p. 6). The WISH project, with an ambitious team of four ITC members, began the journey to identify the training that would empower the traditional faculty who have long been the mainstay of our universities to become the innovative teachers of the next generation. The task is urgent; the challenge formidable, and the journey exciting in every way.

Acknowledgements

My thanks to Dr. Michael Burke, Dr. Julie K. Little, and Mr. Shane Colter for their collaboration on the project and their careful proofing of my work. Thanks also to Dr. Jean Derco who gave the very first version her careful attention.

A Rose By Any Other Name Could Be a Daisy! How the Words Might Make a Difference.

Alfred Benney.
Fairfield University
Fairfield, CT 06430-5195
benney@fair1.fairfield.edu

Faculty do not often engage the problem of designing research tools that evaluate the effectiveness of specific technologies in teaching/learning. When we do, we most often defer to student comments (e.g., "I liked the PowerPoint slides a lot!") which tend not to be very analytic or to our own informal observations. While data from a well-designed research study would help us to make better choices regarding pedagogical strategies using technology, it seems more common that we make those choices based on "teacher's instinct" and "what I like to do." It is hard to justify using the very latest technology simply because it is exciting and new. It is equally difficult to argue that we should teach students presentation skills when our content area is math.

Clearly the complexities of pedagogy stand in the way of developing assessment tools that evaluate the real impact of technology in teaching/learning in complex subject domains. Not only do teachers need to consider student learning styles in designing instructional materials, but they must also take into account the needs of their discipline as well as their course content, development, texts and objectives. Much of the literature on developing technology for learning seems to focus on the potential of the hardware/software toolbox rather than the potential of the learner.

In this short paper, I propose to develop and explore a taxonomy of characteristics specific to different educational disciplines. I do not expect this list to be exhaustive. The goal is to develop a research question that identifies discipline-specific needs that can be linked with specific technology-using pedagogical strategies (Benney, 1999). I suggest that the following list of "Primary Course Characteristics" illustrates my beginning point. To each is attached descriptive attributes and what seems to be an obvious connection with a discipline, a field of study or a specific learning problem. This is an exploratory and experimental approach.

Primary Course Characteristics:

1. Content intensive -- the major emphasis here is factual information presented in formulas, laws or contained in a relational database. There are many applications from engineering data to the phone book. Historical information certainly needs a factual base, but most historians would claim it is more than that. Comment -- It seems obvious that presentation software, web pages and video, like text, can present even relatively complex factual information. But can a documentary film present the information needed by a history class in a way that simple text could not? Would a 30 minute "talking head" interview with an eye witness to the Vietnam war provide a more interesting learning experience than six 5 minute clips on various aspects of the same topic? What is appropriate for the content needs of the course?

2. Analytical -- reducing an idea to its logical components, but also in a laboratory setting (broadly defined), the strategy of experimentation. Comment -- The noted scholar of Theology, Bernard Cooke has suggested that the biggest problem in undergraduate education today is that students cannot read! He explains that students cannot extract information - analyze the information - from text (Benney, A. (2001). How can technology be used to exemplify analytic skills and/or to demonstrate the process? When the process is the objective, it seems experience becomes more important than data.

3. Poetic -- the use of words or images in a metaphorical and imaginative way to stimulate the creative interpretation of the learner. This could be practical in developing inventions or simply entertaining. Comment -- Is it possible to teach creativity? Or can it only be exemplified? Does using a computer to demonstrate puzzles that have multiple solutions or requiring students to develop their own problem-solving web sites encourage creativity? This is another example of a process being central to the learning objective.
4. Organizational -- More the development of managing strategies, but also implies the need to understand social and psychological structures in a practical way. 
Comment -- The use of role playing games as well as video presentations of cases for discussion and analysis have the potential of teaching (again by example) the skills needed for management tasks. Simulations have an effective application in many educational settings. For example, a flight simulator lets you learn from your mistakes and walk away unscathed.

5. Theoretical -- Similar to “Poetic,” tries to get at the underlying reasons for why things are the way they are; grounded in fact and logically constructed.
Comment -- Are students so programmed that they think every question has an answer or is it possible to teach the hypothesis behind the question? Perhaps concept mapping that layers the question could exemplify the process of developing theories.

6. Sensory -- certainly oriented towards entertainment and enjoyment. Art, music and theater dramatizes the human environment. But the skill of a surgeon as well as a pilot have a sensory element.
Comment -- One of the best examples of an application of media to support this characteristic is M-TV. What is missing from a flight simulator is the "feel" of the controls – something essential to actual flying.

7. Manipulative -- forming artifacts from raw materials as in any manufacturing or construction process. The process itself is described in a complex series of interrelated steps.
Comment -- This is a clear case of providing instructions using video examples or animated step-by-step cases. But either the students must commit the process to memory or have the example available at the time of need.

8. Linguistic -- the basic art of communicating through words, symbols and images requires both the memorization of vocabulary as well as the experience of syntax and grammar none of which may have any rational foundation.
Comment -- The benefits of audio tapes, video and animated clips are well documented in language learning. Repetitive hearing, seeing and doing clearly facilitate the development of communication skills. But motive still remains a problem and it would seem that the task of memorizing vocabulary would make text more useful because it is more portable. Can technology motivate or would the possibility of contacting foreign language speakers via the web discourage learners who progress slowly?

This list is not final, but is intended as a place to begin a conversation. I hope that discussions with technology users/teachers from different content areas will lead to a refinement and clarification so that it might be possible to use these discriminators to design multimedia applications that are appropriate for discipline specific objectives.

Partial Bibliography

To develop a scientific way of reasoning and to understand macroscopic phenomena discovered by modern science and their applications to practical fields such as nanotechnology, molecular genomics or proteomics, students need robust mental models of atoms, molecules, and their interactions. Such understanding allows students to grasp what lies at the heart of modern biology, chemistry, and physics. There is considerable evidence that students have major misconceptions about atoms and molecules, and few ideas about how the forces and motions at this scale relate to macroscopic properties.

The Molecular Workbench project (http://www.concord.org/workbench/index.html), which is funded by the US National Science Foundation, is studying the effectiveness of using highly manipulable molecular dynamics models to enhance student learning. It facilitates learning through the use of guided inquiry about the connections between microscopic and macroscopic properties of materials. To this purpose we are creating atomic-scale models, several macro-scale simulations with interactive Flash applications, and are using an integrating language called Pedagogica. In collaboration with teachers, instructional materials using these tools are now being tested in a variety of middle and high school classrooms.

Our Molecular Workbench model can already demonstrate states of matter, gas laws, phase change, latent heat, diffusion, gas absorption, osmosis, thermal diffusion, conformational changes, and some of the properties of liquid crystals. Using scaffolded models and supporting curricula, students are able to predict new micro-macro connections.

The Molecular Workbench2D and Molecular Workbench3D (formerly called Oslet) are molecular simulation engines developed for the project. MW2D is written in pure Java. MW3D is written in Java and Java3D. The models are based on molecular mechanics, an important part of contemporary computational chemistry and biology. MW2D develops an object-oriented framework (OOF) for interactive molecular simulations. The core of OOF provides software abstractions of basic objects for atoms, molecules, fields, boundaries, data sets, and the interactions among them. MW2D consists of four major functional modules: a builder, a viewer, a simulator, and a data analysis environment. The software abstraction model in the OOF provides the interfaces for these modules to interact and integrate.

Pedagogica, which was developed by Paul Horwitz originally to control a genetics simulation called BioLogica, has now been interfaced with MW2D. Pedagogica simplifies the conversion of open-ended models and tools into learning activities that support guided inquiry and generate specific, useful assessment data. We call the combination of a model with Pedagogica a "hypermodel".

Pedagogica is a client application that controls models and their appearance, displays what options are available, receives input concerning the state of the model, controls the interactions with the user, and coordinates other resources that might be used with the model. Pedagogica not only facilitates student choices, but also queries the users and monitors their progress.

The curriculum activities are designed to encourage students to uncover key attributes of molecular systems, develop their own models, and test these against a professional model. Proprioceptive activities with visual feedback, a "virtual construction kit" to arrange molecules in polymer chains, explorations with interactive models followed by discussions revealing the explanatory and predictive power of the models -- all work to build and enrich the student's mental models of the connection between macroscopic phenomena and molecular worlds.

Eight curriculum activities on Atoms in Motion, and a week-long "mini-unit" on States of Matter, both based on
atomic-scale models have undergone formative testing and are now undergoing summative testing in public middle school 8th, 9th and 11th grade classrooms. The activities include integrated hands-on labs, computer modeling, and kinesthetic modeling activities. New research modules on Chemical Bonds and Solutions will be tested this Spring and Fall.

Our primary research questions are:

- Does experience with such a tool help students in 8-9th grades internalize accurate mental models of atomic-scale phenomena, and
- Does this in turn help them become more expert in reasoning about phenomena at different levels, from micro to macro.

We are conducting our research now. Students to date have been highly engaged, responsive in discussions, and have made connections between the various types of activities conducted. For example, they performed a computer simulation and a kinesthetic simulation of kinetic energy exchange between gaseous atoms during collisions—in other words, heat transfer through direct mixing of atoms. Their written responses regarding these activities indicated that most found both the computer and kinesthetic experiences helpful in understanding the concept and that doing both of them was better than doing one or the other.

For more details about the project, including the software, images and descriptions of activities, scripted hypermodels, and curricula, see: http://www.concord.org/workbench/download.html

Boris Berenfeld, co-PI: Dr. Berenfeld oversees the curriculum design and development. With a Ph.D. in radiation biophysics, he combines his interest in frontier science, curriculum design and networking technologies to advance the quality and accessibility of science education. His current research involves innovative approaches to teaching biochemistry through visualization. He has led innovative educational initiatives in Russia, Europe, Latin America, United States and in the Middle East, organized several East-West Conferences on New Technologies in Education, and served on the faculty of the Salzburg Seminar.

Qian Xie at the Concord Consortium is the primary scientist on the project, responsible for developing the algorithms and designing the Molecular Workbench code. Dr. Xie is a computational scientist with a PhD in Materials Physics from University of Science and Technology, Beijing, and post-doctoral experience at the Max Plank Institute in Dresden and at the University of Cyprus. He has developed the Molecular Workbench core software.

Dan Damelin teaches Chemistry and coordinates the computer lab at Lincoln-Sudbury High School. With a MAT from Tufts in Chemistry, Biology and General Science, and a triple major BA from Tufts that included computer science, he has been able both to develop and to test Molecular Workbench activities.
Abstract: This paper presents a case study in adapting an existing educational pen-based groupware system for use in a distance-learning environment. After reviewing the key characteristics of the original educational groupware system, we describe our motivation for adapting the system for use at a distance. Next we describe the process that was used to carry out this adaptation, the problems that were encountered, and the resulting solutions that were developed. The paper concludes with the results of a user study demonstrating that the modified system can be successfully used at a distance.

Background and Introduction

Software that supports cooperative work, often called groupware, is commonly classified as belonging to one of the four quadrants of the time-place matrix shown in the following table (Ellis et al. 1991).

<table>
<thead>
<tr>
<th>Same Place</th>
<th>Different Times</th>
</tr>
</thead>
<tbody>
<tr>
<td>I</td>
<td>II</td>
</tr>
<tr>
<td>III</td>
<td>IV</td>
</tr>
</tbody>
</table>

Table 1: Groupware Classification

For example, on-line chat systems belong to quadrant III of the matrix, while electronic mail systems belong to quadrant IV. The interested reader is referred to (Baecker, 1993) for an excellent overview of groupware systems including some examples of educational groupware that fall into each of the time-place categories noted above. The goal of the current paper is to describe a case study in "changing places"; specifically we describe our work in adapting an existing pen-based educational groupware system from the "same time, same place" paradigm to the "same time, different places" paradigm.

In the remainder of this introduction we describe the DePauw Electronic Black Board for Interactive Education (DEBBIE), a groupware system originally developed by the first author for enhancing the way students and teachers share written information during class (the DEBBIE system is patent pending). In subsequent sections we describe the process of adapting DEBBIE for use in a distance environment, the obstacles we encountered and our progress in overcoming them, and an evaluation of the resulting system.

DEBBIE was originally designed as a same time, same place groupware system and has been in regular use...
since the spring semester of 2000. Courses that use the DEBBIE system meet in DePauw's electronic classroom, which houses one instructor station and sixteen student stations (Fig. 1). Each of these seventeen stations is equipped with a Pentium PC that uses a high-resolution flat-panel pen-based video tablet as its display device (see WACOM 2001). Our electronic classroom is distinguished from others that are described in the literature (see for example Shneiderman et al. 1995) by the fact that users can control the computers using a special electronic stylus in addition to using a keyboard and mouse. For example, when running a standard "paint program," a user can use the electronic stylus to make a sketch by drawing freehand directly on the surface of the video tablet. Allowing this type of freehand input is extremely useful when teaching topics that are hard to draw using only a keyboard and mouse. Examples include diagrams of molecules in a chemistry class, graphs in an economics class, complex formulae in a mathematics class, musical notation in a music theory class, and finite state machines (Fig 1.) in a computer science class.

The teacher's station is attached to a large rear-projection electronic whiteboard (see SMART 2001) located at the front of the room. The image from the teacher-station's video tablet is also displayed on the electronic whiteboard. Since the electronic whiteboard is touch-sensitive, the teacher can use a finger (or just about anything else) to draw directly on the surface of the board as an alternative to writing directly on the video tablet. The display on the electronic whiteboard is approximately five feet wide by four feet high and requires approximately four and one-half feet of space behind it for the projection system. In our classroom the projection system actually sits behind the classroom's front wall so that the display surface of the electronic whiteboard is flush with the standard (non-electronic) whiteboards that flank it on each side.

Figure 1: Electronic Classroom

DEBBIE allows the students and teacher in a pen-based electronic classroom to share written information during class. For example, when using the system, the teacher can extemporaneously draw freehand sketches directly on the surface of the teacher-station's video-tablet or electronic whiteboard. The teacher can also use a keyboard to type material, and can import material that was prepared ahead of time for use during class. All information sketched, typed, or imported by the teacher is transmitted over a network so that it appears on each student's video tablet.

Each student can write freehand on his or her display to make private annotations to the teacher's material. During class the teacher can import portions of a student's workspace for viewing and discussion by the entire class. Because of this, class sessions tend to unfold as highly interactive activities. In a typical scenario the teacher first presents some new material to the class and then asks the students to sketch answers to problems that are related to this material. The teacher then uses the system to share some or all of the student's answers with the class, responds to questions about these answers, offers alternative solutions, and determines if the class is ready for new material in which case the cycle repeats.

In order to accommodate an entire class session, each user's workspace is indefinitely scrollable in the vertical direction like a word processor, and each user can scroll through the workspace independently of the other users. At the end of the class period each user's workspace can be printed or saved for later retrieval. Portions
of the workspace can optionally be "replayed" in a stroke-by-stroke fashion that, for example, allows a student to review how a complex diagram evolved. The reader who is interested in more information about the software itself is referred to (Berque et al. 2000) for a more complete description of the system's user interface.

The first author has taught four upper-level college classes that were delivered entirely using DEBBIE, and other faculty members have used the system to conduct individual class sessions in several other disciplines including mathematics and history. Attitude surveys demonstrate that students believe they are more attentive when using the DEBBIE system and that they prefer this environment to a traditional classroom. While admittedly anecdotal, comments from anonymous student course evaluation forms also indicate student satisfaction with the system (Fig. 2). The interested reader is referred to (Berque et al. 2001) for a more detailed and quantitative description of students' reactions to the system.

```
This level of interaction in this class is more than I have experienced in any other class. There is a lot of interaction between the teacher (you) and us that has been very valuable. I don't think this could have been achieved outside of the DEBBIE classroom.
```

Figure 2

The Adaptation Process: Motivation, Goals, and Methods

Our motivation for adapting the DEBBIE system for use at a distance stems from several sources. First, instructors at other schools have expressed interest in using the DEBBIE system to support traditional synchronous distance education classes where some or all of the students may be taking classes from a large number of remote locations. We also envision more limited scenarios in which the students and faculty may be located at only a small number of locations. For example, the Computer Science Department at the authors' home institution does not currently offer a course in "Analysis of Algorithms" although such a course is offered by the Computer Science Department at a neighboring college located approximately thirty miles away. Conversely, the neighboring college does not offer a course in "Human Computer Interaction" although such a course is offered at the authors' home institution. It is easy to see that an agreement enabling students at each campus to take classes from the other school remotely would be mutually beneficial. Each school could provide a distance-learning classroom with network and audio connections to the corresponding room at the other school. In this case all of the students would attend classes in one of the two classrooms.

As we began to consider what would be required to adapt DEBBIE for use in a distance education environment we decided to operate within a framework formed from several underlying assumptions. First, we assume that DEBBIE classes will be delivered synchronously since DEBBIE's feature set is built around the notion of same-time interaction. In addition we assume that DEBBIE will be used to transmit data between the teacher and students, while an external system such as a telephone-based or internet-based conference call will be used to provide a bi-directional audio link. Since reliable and inexpensive audio links are readily available, we see no reason to try to replicate this functionality within the DEBBIE system. Further, since fast, reliable, inexpensive video links are less common, we assume that none will be available for use during a DEBBIE class. Thus we need to ensure that users can interact using DEBBIE even if they cannot see each other. Finally, and most importantly, we strive to provide the same feature set for remote users that we have been providing to local users of the DEBBIE system for the past several years. For example, since students who are in the same room as the teacher can use DEBBIE to share their work with the rest of the class, we insist that remote users have access to the same functionality.

Major Problems Identified and Resolved

Working within the framework outlined in the previous section, we developed a list of problems that would interfere with the use of the original version of DEBBIE in a distance environment. These problems were then categorized as "critical", "high priority", or "low priority." Problems were assigned a critical rating if DEBBIE simply could not be used in a distance environment until this problem was resolved. An assignment of "high
priority” indicated that a solution to the problem would significantly enhance the experience of remote users, while the “low priority” category was used for problems whose solution would have less of an impact. This problem categorization was subsequently used as a guide during the development phase of the project as we designed, implemented, and tested solutions to the problems starting with the critical ones. Approximately ten problems were addressed during the process of augmenting the DEBBIE system for use in a distance environment. Although a detailed description of every problem is beyond the scope of this paper, we summarize several of the problems and their associated solutions below (Tab. 2). The problems were selected to give the reader a feeling for the range of issues that were addressed.

<table>
<thead>
<tr>
<th>Descriptions of Example Problems</th>
<th>Associated Solutions</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Problem 1.</strong> Students at a remote location cannot see the electronic whiteboard by glancing at the front of the room the way local students can. Therefore, if the teacher points to an item on the board and says “Look how this works...” the remote students will have no way to know what the teacher is pointing to.</td>
<td><strong>Solution 1.</strong> The augmented version of DEBBIE includes a new telepointer tool. Selecting this tool causes a pointer icon to track the teacher's hand movements on the electronic whiteboard or video tablet. Since this icon is also displayed at the corresponding location on each student's display, the students can easily determine what the teacher is pointing to.</td>
</tr>
<tr>
<td><strong>Problem 2.</strong> Since each user's scroll can be positioned independently of the other users, students at a remote location will experience difficulty each time the teacher's scroll is moved to a new position. Local students can glance at the electronic whiteboard at the front of the room, notice that the teacher's scroll has been repositioned, and then reposition their scrolls appropriately. However, remote students have no way to get this visual feedback.</td>
<td><strong>Solution 2.</strong> We added a toolbar button to the student version of DEBBIE that displays one of two images to signify whether or not the student's scroll is currently synchronized with the teacher's scroll. If the student's scroll is not synchronized, the student can click on this button, which causes the scroll to be adjusted appropriately. We also added an auto scroll feature which, when enabled, causes a student's scroll to adjust automatically as the teacher's scroll position changes.</td>
</tr>
<tr>
<td><strong>Problem 3.</strong> When working with local students, the teacher can simply look into the classroom to see who is present. This can help the teacher to determine when enough students have arrived to start class, who to mark absent for a given day, and who to call on to answer a question. However, when dealing with remote students the teacher has no easy way to sense who is participating in the current class session.</td>
<td><strong>Solution 3.</strong> The augmented version of DEBBIE requires each student to log into a DEBBIE session with a username. The teacher can then display a list of the currently connected users, and can use this list to import portions of selected student's notebooks. Students who join the class late will be added to the list as soon as they are connected and they will automatically receive the content transmitted by the teacher earlier in the class.</td>
</tr>
<tr>
<td><strong>Problem 4.</strong> The teacher can transmit hypertext links (to spreadsheets files, movie clip files, etc.) to the students by inserting the links into the electronic notebook. If the linked files are located in a shared directory on a local area network, each local student will then be able to open the file. Since remote students will generally not have access to the local area network, they will not be able to open these files.</td>
<td><strong>Solution 4.</strong> In the augmented version of DEBBIE the teacher can transmit a hypertext link that refers to a URL for the external file. The first time the student clicks on this link an FTP client is automatically launched to download the specified file to the student's PC. To handle subsequent references to this file by the student, DEBBIE simply opens this local copy of the file.</td>
</tr>
</tbody>
</table>

Table 2: Example Problems and their Solutions

**Evaluation and Results**

After receiving approval from the Institutional Review Board (Human Subject Review Board), we invited seven Computer Science majors to participate in a usability test to determine whether or not the augmented version of DEBBIE could be used in a distance education environment. All seven students agreed to participate in return
for a gift certificate to a local restaurant, and they met as a group with the authors in our electronic classroom in order to begin. After signing an informed consent form, each student was given a pre-test consisting of six questions on the topic of “Regular Expressions.” This topic was selected because: (a) we believed most students would have little prior experience with this area of Computer Science, (b) it is a topic that the first author regularly teaches in one of his advanced classes and therefore he had a good sense of how to present the material, and (c) the topic involves complex notation that is best explained using free-hand sketches.

After the pre-tests were collected, the students were given a five-minute orientation to the DEBBIE system. During this orientation the students learned how to create a new electronic notebook, connect to a network session, draw and erase using the electronic stylus, and navigate through the notebook. At the conclusion of the orientation session the first author went to a nearby classroom that had been temporarily equipped with a PC running the teacher's version of DEBBIE. A bi-directional audio link, external to the DEBBIE system, had previously been set up between the teacher's classroom and the student's classroom. When the teacher arrived at his classroom, he used the audio link to tell the students to connect to the DEBBIE session. The teacher then used the DEBBIE system to monitor the students as they connected to the session.

When the teacher saw that all of the students had connected, he began to teach a thirty-minute class on the topic of Regular Expressions. The class started as a lecture with the teacher presenting new material by transmitting extemporaneously drawn free-hand sketches using DEBBIE while simultaneously offering an oral explanation. During this time the teacher frequently used the telepointer to focus the student's attention on specific content matter, and the students used the auto synchronization feature to keep their scrolls synchronized with the moderator. The students were also free to use their electronic pens to make personal annotations alongside the instructor's material. Next the teacher had the students work through several interactive exercises that required the students to sketch answers to problems using their electronic pens. At the end of each exercise the teacher collected the student's answers electronically and quickly read them over in order to gauge how the class was doing. At several points the teacher chose to share one or more student solutions with the entire class so that alternative approaches could be compared. While explaining the correct answer to one of these exercises the teacher intentionally introduced a mistake into his explanation. In response the student participants quickly interrupted the teacher by calling out a correction thus providing additional evidence that the students were actively following the session.

At the conclusion of the class the students were given a post-test consisting of exactly the same questions that comprised the pre-test. A faculty colleague in the Computer Science Department who was not associated with this study graded the pre-tests and post-tests. The tests were provided to the faculty member in coded format so that he could not tell which were pre-tests and which were post-tests. In addition, the student's names were not revealed to the faculty grader. The results (Tab. 3) indicate a dramatic improvement on the post-test scores as compared to the pre-test scores.

Table 3

After completing the post-test, the students answered some questions that were designed to measure how well they perceived they had learned the material. These questions were answered using a semantic differential scale with endpoints defined with 1 meaning very comfortable and 5 meaning not at all acquainted. When the students were asked to use this scale to rate the statement “Prior to participating in the session today how comfortable were you with the concept of a Regular Expression?” the mean response was 4.4. When the students were asked to rate the statement “After participating in the session today how comfortable were you with the concept of a Regular Expression?” the mean response was 1.6.
The user test described in the previous section was carried out using computers located in close proximity to each other and connected to the Internet via a relatively fast 10-megabit local area network. In order to determine the responsiveness of the system when used in a variety of different configurations, we carried out several additional tests. Specifically, we measured the time required to transfer a section of an electronic notebook consisting of a question posed by the teacher along with the student's associated answer between two computers under a variety of conditions. We repeated the test several times, each time using a section of an electronic notebook that had been saved during a real class session. When DEBBIE was used to transfer these sections between two computers that were both located at the author's own University, the transfer times ranged from 229 milliseconds to 1,463 milliseconds. Next we established a DEBBIE session between a computer at the authors' home institution (located in the USA) and a computer located at a University in England that was also connected to the Internet via a 10-megabit local area network. The transfer times remained similar in this scenario, this time ranging from 492 milliseconds to 1,483 milliseconds. Finally, we established a DEBBIE session between a computer at the authors' home University and a computer using a 56K modem to connect to the Internet from a local home via a community-based Internet Service Provider. The transfer times were somewhat slower in this scenario, ranging from 1,379 milliseconds to 6,386 milliseconds; however, these times demonstrate that the system can perform one of its most communication intensive tasks interactively even under sub-optimal network conditions.

Conclusions

The user test described in the previous section has demonstrated that the augmented version of DEBBIE can be used to support classes delivered at a distance, even when those classes use a mixture of pedagogical approaches ranging from a lecture-based approach to an approach that incorporates more student involvement. The responses to the survey questions presented in the previous section show that the students perceive that they are learning while using DEBBIE in a distance environment, and more importantly the results of the pre-test and post-test provide evidence that the students really did learn the material. Finally, the networks tests demonstrate that DEBBIE continues to perform interactively even under sub-optimal network conditions. Collectively these results encourage us to try to use DEBBIE to deliver an entire distance education course.

Prototyping the Development of Groupware to Help Low-Vision Students
View an Instructor's Blackboard Notes

Ben Betz, Computer Science Department, DePauw University, USA, bbetz@depauw.edu

Abstract: The current lack of satisfactory technology to aid low vision students drives the development of a handheld Windows CE-based viewer for Visually Impaired Students (v-VIS) designed to assist in the realtime visualization of professor-written blackboard material. Instead of writing on a normal blackboard, the instructor writes on an electronic whiteboard. Students with normal vision view this material in the usual way, namely by looking to the front of the room. Simultaneously, the v-VIS system transmits the whiteboard contents, in realtime, to the low-vision student’s handheld computer where it can be magnified and viewed at close range. After describing the v-VIS system, we discuss some of the problems we encountered during its development and our methods of overcoming these problems. Results of preliminary user testing are also presented.

Introduction

Classrooms present inherent problems for low-vision students, including difficulties reading written information on blackboards. In traditional classrooms, a significant portion of the lecture or discussion depends on the student’s ability to refer to this visual information. Thus, students with reduced vision often employ human note-taking services to transcribe blackboard writing for later review. While utilizing such a service provides the student with a copy of the professor’s writing, it is not immediate and it is subject to human misinterpretation of the blackboard information. Our current research has centered on designing a networked computer system called v-VIS (viewer for Visually Impaired Students). The prototype is designed to alleviate note-taking difficulties by providing immediate access to blackboard writing for low-vision students. Thus v-VIS is an example of assistive technology, the use of technology to aid disabled persons, which as (Perkins, 2001) states, may be the best method of providing immediate access to class information.

Interestingly, while significant prior research has developed assistive technology for completely blind users, little effort has been made toward helping the much larger population of low-vision users. Low-vision persons, who can make functional use of some portion of their vision with appropriate aids, likely outnumber fully blind persons three to one (Jacko, 1998). Our work on v-VIS serves this audience.

In the simplest sense, v-VIS collects the information written on an electronic whiteboard (instead of the traditional blackboard) and transmits it to a handheld viewer near the student (see Fig. 1 and 2). This viewer not only displays a copy of the professor’s writing in realtime, but also enhances it through magnification and color palette manipulation, which according to (Kline, 1995) are essential features for low-vision GUI accessibility. The v-VIS prototype uses a recent advent in mobile computing technology, the Handheld PC, for the viewer hardware, which classifies v-VIS as mobile assistive technology. This allows for increased portability of the system as well as several advantages that will be described later.

Prototype Development

The current v-VIS prototype has been developed for a Handheld PC running Windows CE 2000. While a Handheld PC has a relatively small screen (approx. 2" x 5"), we feel that a handheld will provide several advantages over a desktop system. One benefit is that the low weight of a handheld allows it to be lifted to the user’s eyes, greatly reducing the neck strain that many low-vision computer users experience when leaning too close as one inch from the screen (Vener, 1988). Handheld PCs are also portable devices, which allows them to be used in multiple locations, especially when configured for wireless networking. Additionally, the hardware chosen for v-VIS is one-fourth the cost of the desktop system that would be required to achieve similar functionality.
The v-VIS Interface

The foundation of the v-VIS interface is the draw space; the main screen of v-VIS is dominated by a large, blank panel (see Fig. 2). When the professor wishes to write a particular item for the class to see, he moves his finger (or stylus) on the large touch-sensitive rear-projection whiteboard screen (approx. 4' x 5') and writes just as he would on a marker board or chalkboard. A desktop computer attached to the whiteboard runs the professor or “moderator” version of the v-VIS software and interprets each motion, laying digital “ink” onto the draw space. Students with normal vision view the professor’s drawing by looking at the large image on the whiteboard. v-VIS also transmits the coordinates of each ink “droplet” in real-time over a high speed network to the viewer, which then recreates the image on its screen for the low-vision student, after adjusting for his or her magnification and color preferences.

As each screenful of space is used up, a new panel or “page” of drawing space is automatically made available. In fact, the v-VIS panels are infinitely scrollable in the vertical direction, as if each new page was taped to the bottom of its predecessor. Due to the smaller handheld screen of v-VIS, each panel is also scrollable in the horizontal direction, to allow the full width of the whiteboard draw space to be viewable on the handheld. In this way, the handheld becomes a viewing “window” into the selected page of the whiteboard draw space.

Beyond the basic interface specifications, v-VIS is designed to operate in a flexible manner. The goal has been to make the system as customizable as possible, so that it may best serve the needs of students with many vision impairments. According to (Jacko, 1998), assistive devices must be fully configurable in order to serve the large range of vision profiles that exist. Thus, the v-VIS viewer prototype has multiple control methods and two independently configurable image enhancements—magnification and color customization.

Interface Control

Control of the handheld viewer is accomplished in many ways. As with most current software packages, a menu-toolbar set is accessible at the top of the screen. This may not be functionally visible to low-vision users, however, so every command has a keyboard shortcut. Scrolling, for example, is accomplished in three different ways: By using the stylus to control the scrollbar, by using the arrow keys, and by selecting a “grabber tool” that allows the user to place a stylus on the draw space and drag it to its desired position, much like moving a piece of paper to a different location on a desk.

Magnification

Magnification is one of the most important visual enhancements for a low-vision person (Fraser, 2000). Making the drawn objects larger allows students with low visual acuity to see the objects more clearly, effectively capitalizing on their available vision (Jacko, 1998). v-VIS takes the mathematical description of
each drawn object and scales it by a factor ranging from 100% to 1000%, which is set by the user according to his or her individual needs. Not only do the dimensions of the objects increase, but so does the thickness of their defining lines, making the digital ink appear as if it were being examined under a powerful, distortionless magnifying glass (see Fig. 3).

![Figure 3: Effects of magnification in v-VIS](image)

**Color Customization**

As important as magnification is to the use of v-VIS, many persons with reduced vision cannot see even magnified images unless they are presented in specific colors or contrast schemes (Kline, 1995). For this reason, the draw space of v-VIS can be set to use any combination of colors. Both the background and four distinct drawing colors can be chosen from any RGB value based on the user’s specific needs.

**User Response**

Two low-vision persons have informally evaluated and commented on the v-VIS prototype during its development. One of these evaluators was pleased with the magnification features of an early version, but made several suggestions for improving the color customization option. The second evaluator also found the magnification settings helpful. This person did, however, mention a preference for a larger monitor, since it can display the same amount of draw space as the whiteboard. Since she cannot see to the front of the room, she has no indication of where on the large screen the professor is writing when looking at the image on the smaller handheld screen. She felt a larger monitor would help her locate the newest writing on the screen with contextual relation to previously drawn objects. Interestingly, this evaluator also suggested the addition of auditory feedback to signal the arrival of new information to the viewer, since writing on the whiteboard does not make an audible sound like chalk on a blackboard does. Thus the evaluator was concerned that she would have trouble knowing that new drawings had arrived at the viewer and discerning where to look for them.

**The Object-In-View Problem**

As mentioned by one of the evaluators, the handheld’s limited screen size makes it difficult to know where the professor is writing. The large whiteboard and the smaller handheld screen display corresponding images, but the complete whiteboard image cannot appear on the handheld at any given time, since this requires reducing its size. v-VIS aims to make the professor’s writing more visible for a low-vision student, not to shrink it. In fact, it is likely that reduced-vision students will have their view magnified, centering on an even smaller section of the professor’s writing. In our prototype, the handheld maintains the same amount of draw space as the large forward display, but only a portion of it is visible at any given time. The student’s view thus acts as a scrollable “window” into the whiteboard draw space, like a camera zoomed in on one particular section of the whiteboard. The major problem for low-vision students is that as the professor draws new objects on the whiteboard, it is not likely that they will be within the current window’s focus on the handheld. In this situation, the new writing will not be displayed on the handheld until the view is scrolled to its location on the draw space. We call this the object-in-view problem.

This problem is only a minor inconvenience for a user with normal vision, who simply has to look at the
whiteboard and reposition the viewing window on the handheld to the area where the professor is writing. The users of v-VIS, however, will likely have no ability to see the whiteboard or the professor. Therefore, not only will it be impossible for them to adjust their scroll, but they will have no indication as to how the newest drawings are oriented among previous writing. Since the professor will likely write several v-VIS “pages” of information during a class session, the draw space can be expected to change numerous times. A low-vision user cannot be expected to follow along with the rest of the class without an effective, automatic method of displaying new writing on the handheld viewer as the draw space contents change. We have attempted to develop a solution for this problem, a feature called AutoScroll.

AutoScroll - A Possible Solution

The solution to the object-in-view problem that has been developed is called AutoScroll. As the viewer receives new objects drawn by the professor, it repositions its scrollable draw space to place the newest object on the screen. This is similar in functionality to a visually enhanced text editor, MAGNEX, which maintains the cursor, and thus new text input, near the center of the screen (Vener, 1988). Initial efforts have also been made in v-VIS to ensure that previously existing objects nearby are retained on the screen.

The basic principle behind AutoScroll is rather simple: If a newly received object is not completely visible on the screen, the system automatically repositions the draw space so that it is. At the same time, AutoScroll attempts to retain the context of the newest object by keeping other recently drawn objects on the screen. This is especially important to low vision students who have no other means of knowing where the newest information is being written. By keeping nearby and often related objects on the screen, AutoScroll provides contextual information to the v-VIS user.

AutoScroll is based on the fact that each object drawn on the v-VIS screen has a bounding box, a rectangular set of boundaries that define the object's position (see Fig. 4). This box allows v-VIS to easily determine if an object is visible at all and if it is, the portion of the object that is visible on screen. The algorithm uses a Tolerance Frame to determine if a newly received object is completely on screen (see Fig. 5). This frame is a small area around each edge of the viewing area outside of which an object is considered to be out of view. The Interior Tolerance Border marks the beginning of the frame on the inside of the viewing area, and the Exterior Tolerance Border marks the outside edge of this area.

Figure 4: An object with its bounding box crossing the Interior Tolerance Border

Figure 5: AutoScroll borders

When new objects are received, their bounding box location is compared to the location of the Interior and Exterior Tolerance Borders to determine what portion of the object is visible. If an object's bounding box is completely outside of both borders, the draw space is automatically scrolled so that the object is just inside the left and/or upper Interior Tolerance Borders; this action is called a “jump” (see Fig. 6). The draw space is only scrolled in the direction this border is crossed, so the Interior Tolerance Border is not really a rectangle, but a set of four boundaries that extend across the entire view. AutoScroll has been designed in this manner to move new letters (drawn objects) that are far from the current location of the viewing window to the left of the screen, providing space for the letters the professor may soon write. Preference is also given to the upper half of an object in the event it is too tall to fit completely on screen, since the upper half of handwritten letters is more recognizable than the lower half (Lynch, 1999).
If an object has crossed the Interior Tolerance Border but some part of its bounding box still resides inside the Exterior Tolerance Border, AutoScroll performs a "slide." Here, the scroll places the object just inside the Interior Tolerance Border that was crossed (see Fig. 7). Slide actions are designed to place in view objects that are close to the current location of the viewing window while keeping other nearby objects on screen as well. This allows the completion of words that are being continued to the right, making them visible without pushing the first portion of the word off the left edge of the screen, which would happen if a jump action occurred. Slides then function to group letters of words together as the professor writes them and also to group phrases to relate the context of new words.

![Image of a "jump" repositioning of an object]

**Figure 6:** A "jump" repositioning of an object

![Image of a "slide" repositioning of an object]

**Figure 7:** A "slide" repositioning of an object

**AutoScroll Performance**

The performance of AutoScroll was evaluated objectively by counting handwritten word completion as described below. Ten pages of data recorded from a class taught on an electronic whiteboard were fed to the v-VIS viewer stroke-by-stroke. Two statistics were collected at multiple zoom factors:

- **How many times the most recent word was completely on the screen when it was fully received**
- **How many complete words were concurrently on the screen at that time**

![Bar chart showing Word Completion as a Function of Zoom Factor]

**Figure 8:** Completeness of one word

![Bar chart showing Completeness of n or More Concurrent Words 100% Zoom]

**Figure 9:** Completeness of n or more words

(Fig. 8) shows that AutoScroll is effective at grouping individual letters into words. Even at 400% magnification, 80.86% of possible words were completely displayed and close to 100% were complete at the lower zoom factors tested. Performance decreases at higher magnification levels, since the effective draw space is reduced and a large number of letters cannot be physically displayed on the screen. Similarly, the grouping of multiple words on screen at the same time to provide context is rather effective at lower magnification (see Fig. 9). For example, at 100% magnification, 4 or more words were completely on the screen a majority (67.1%) of the time. Again, performance decreased at higher magnification due to the limited screen size.
Conclusions and Future Work

The initial reactions from the two evaluators of v-VIS indicate that the system will likely be helpful in a classroom environment, after several improvements are made. The vision enhancements seem to be quite helpful, although the screen size of the Handheld PC may be an issue.

Based upon the performance test, AutoScroll appears to be a good method of placing the most recent objects on screen, helping to overcome the object-in-view problem. The results of the test, however, suggest that while the AutoScroll algorithm works well, its performance can still be improved, a fact mentioned by one of the low-vision evaluators. The current Tolerance Frame, for example, would most likely result in better performance if it were scaled in size based on the magnification level.

For future work, we plan to continue development of AutoScroll algorithms in order to improve the performance of this feature. The v-VIS interface can also be improved by including the addition of auditory feedback to announce the arrival of new information, indicating the location of the new objects through tonal differences. We also plan to develop v-VIS for a desktop system, so its usability can be compared with the handheld. After continued development, we plan to test the resulting v-VIS system in a classroom with low-vision students to determine its usability in a more formal manner.

This work was supported in part by DePauw University’s Science Research Fellows program and by an REU grant from the NSF (grant number EIA-9911626). Guidance for this work was provided by Dr. Dave Berque of the DePauw University Computer Science Department. The v-VIS system works in conjunction with an earlier software system developed by Dr. Berque, named DEBBIE (patent pending).
Introduction of Technology Integration through Case Based Learning

Abstract
In response to school-needs and state-requirements, the University of Northern Colorado is redesigning the two requisite educational technology courses for the undergraduate teacher preparation programs. The first course redesign has been implemented; the program's one-credit 200-level course is currently equipping UNC teacher candidates with basic computer and software-tool skills. The second requisite course—the 300-level—has been redesigned and is now in stages of development. The first part of the course will instruct teacher candidates in the concepts of technology integration. Then, to make those concepts more meaningful and transferable, the course will immerse students in a case-based learning unit. This proposal describes the unit's problem scenarios. It also details the electronic environment and graphical user interface in which the scenarios and the information necessary for problem solving are presented.

A study by Persichitte, Tharp, and Caffarella (1999) found that while technology is readily available to teacher education programs, only 45% of the programs' faculty regularly use technology during class and only 40% of those programs require preservice teacher candidates to use technology to design and deliver instruction. Those statistics exist despite current standards for technology-use in education.

Recently the Colorado legislature passed Senate Bill 99-154, which included eight standards for teacher education candidates to meet. The seventh standard states, "The teacher is skilled in technology and is knowledgeable about using technology to support instruction and enhance student learning." However, a recent survey of the University of Northern Colorado’s (UNC's) partner schools (i.e., local K-12 schools) found a high need for successful implementation of that standard. In fact, many schools rated teacher technology skills as their highest need. Clearly, preservice teacher candidates have not been equipped to meet the demand for trained teachers who can integrate technology throughout their instruction.

Currently, UNC's undergraduate teacher education programs require preservice teachers to take two educational technology courses. However, each course is worth only one credit. The preservice teachers generally take the first course at the beginning of their teacher preparation
and the second course just before their final student teaching experiences. The courses' curricula vary for elementary, middle grades, and secondary preservice teachers.

In 2000, UNC was awarded a Preparing Tomorrow's Teachers To use Technology (PT3). A major initiative of the grant was to redesign the aforementioned courses so that UNC's School for the Study of Teaching and Teacher Education will better prepare students to meet new standards for using technology for instruction. The first year of the grant, the university's PT3 team redesigned the 200-level courses (i.e., the first educational technology course students take). The PT3 team crafted those courses to give students the technology tools they will need for superior performance throughout their university careers, for successful synthesis of technology integration theories with other learning theory, and, ultimately, for effective classroom teaching. The curricula include introductions to both MAC and PC operating systems and introduce students to a variety of software, including Word, Excel, PowerPoint, Hyperstudio, Inspiration, and Dreamweaver.

Because the 200-level courses emphasize tools, the 300-level courses will concentrate on preparing preservice teachers to integrate those tools and other technology into instruction. The PT3 team wants the 300-level courses to give preservice teachers a picture of how integration looks in K-12 classrooms and how they can use technology integration to meet state standards and solve instructional problems. After determining the course objectives, the PT3 team split into sub-teams for designing and developing the different parts of the courses. The first part of the courses will provide more theoretical information about such topics as instructional design, technology management, and teaching strategies. Although assignments throughout the course will require preservice teachers to apply the concepts they learn, the PT3 felt that situating knowledge-application in a more authentic, problem-based environment would help the teachers better understand all that technology integration involves. Therefore, the team portioned the second half of the courses to be case-based learning scenarios that immerse teachers in rich environments for active learning (REALs).

Constructivist environments, like those of case-based learning, work well when "conceptual complexity and case-to-case irregularity" characterize the information to be learned. Learners of such information need to develop cognitive flexibility in order to transfer their knowledge to other situations and varying problems (Spiro et al., 1992). Constructivist, and especially case-based learning environments permit such development. A case-based learning environment will immerse students in multitudinous information and let them to make the connections necessary for understanding the importance of technology integration and how such integration might look in a classroom setting.

As is characteristic of all REALs, the 300-level courses environments will rely on authenticity as a student-motivator. The environments' authenticity will also give students the opportunity to organize concepts in such a way that they will transfer to the situations they may find in practice (Grabinger, 1996). The PT3 team talked with the university's teacher education professors and K-12 teachers to devise weekly scenarios enriched by reality-based electronic artifacts (e.g., emails from other teachers, phone messages in the form of audio-files). The team wanted the case-based learning unit's scenarios and materials to imitate typical experiences of first-year teachers.

The REALs for the 300-level courses specifically meet the criteria for case-based learning and instruction. Ertmer and Russel (1995) write, "Case based instruction is a teaching method which requires students to actively participate in real or hypothetical problem situations, reflecting the kind of experiences naturally encountered in the discipline under study." Students
actively apply learned knowledge and skills to a problem situation. Ertmer describes these cases to be “ambiguous, messy, and recalcitrant.”

Such a problem lies at the heart of the 300-level REAL. In fact, students must first analyze a fictitious school’s Colorado Student Assessment Program (CSAP) scores in order to define the case’s problem. The unit’s Web site will then offer the resources and information necessary for solving the problem. However, the 300-level course instructors will model ways in which the problems can be solved and will also act as technical and organizational supports.

Throughout the unit’s design and development, the PT3 team made a priority of building instruction that teachers toward the technology standards for teacher education as presented by the National Education Technology Standards and by the state of Colorado. Each piece of the case-based learning unit will enhance students’ understandings of technology integration as well as linked directly to those standards.

The Scenarios

The case-based learning experiences will evolve from initial pretense that a Colorado school has hired the participating preservice teachers for their intended subject matter and grade levels; the unit will ask them to imagine that they have worked all summer to plan for their classes. However, much of that work will be undermined when, in Week One, the teachers receive a “voice mail” (in the form of an audio-file embedded in the unit’s interface) informing them that they have been reassigned to other schools ... with below average standardized-test scores. Week One of the case based learning unit will expose the teachers to data—in the form of school profiles and standardized-test scores—that can acquaint them with the new school’s environment. The Week One graphical user interface (GUI) will provide job-aids and a video-file of a district assessment specialist explaining how to read the test scores. The GUI will also link to electronic “cumulative folders,” all of which will contain report cards and some of which will contain IEPs. Teachers will then analyze the available data and prepare a chart of class and individual strengths and weaknesses, as well as proposed strategies for meeting instructional needs. Also useful for helping the teachers visualize their simulation environments will be a letter embedded in the Week One GUI. The letter will announce that the teacher has received a grant that will provide classroom funding for six computers, a printer, a scanner, a TV, a VCR, a digital camera, and $200 in discretionary funds. In addition to familiarizing teachers with the simulated school environment, Week One must also familiarize them with the unit’s online environment. Although each week’s interface will be self-contained and intuitive, in Week One, the course instructors will model standard procedures.

Week Two’s GUI will first point teachers toward an email from the district technology manager informing them that he has set up their computers, network connections, and peripherals and installed various software. The students can also access the classrooms’ floor plans from the Week Two interface. The two “referrals” the teachers will find within the interface will pose the second week’s problems: While working at the computers, students have been off-task and disruptive; they have not completed their work; and they have been crowding and rough-housing around the computers. To combat those problems and make the best use of the equipment, the teachers must create a list of classroom rules for technology-use. The teachers will also have the option of rearranging the classroom floor plan. To support the performance of those tasks, the GUI will make available a video that shows another teacher giving a tour of her classroom and showing a poster of the technology rules she has implemented.
In Week Three, after teachers are well acquainted with their environments, they will be asked to design instruction for their students. Week Three’s task will be to revise a preexisting lesson plan so that the lesson meets the instructional needs determined by Week One’s data analyses. The modified lesson plans must also use the classrooms’ technology resources to enhance instruction. The Week Three GUI will provide access to a database of lesson plans (i.e., the fictitious lesson plan bank that the teachers spend their summers creating) that do not use technology. Week Three’s GUI will also open a memo that contains a copy of the National Education Technology Standards for Students as well as a memo from the grant-giving foundation reminding the teachers to spend their discretionary funds. In addition, teachers will be able to open an audio-file of a teachers discussing best-practices for integrating technology into the classroom.

Week Four will be framed as a teacher workday. From that week’s GUI, teachers will access collaboration worksheets then work with each other to improve their lesson plans. In Week Five’s GUI, teachers will open a letter from the grant-giving foundation, asking that the teachers submit a report about how they’ve used the resources that the foundation has provided. In this report, teachers will need to reflect on how they can use technology as a tool to support their teaching strategies.

Week Six’s GUI simply offers online resources for solving the problems that course instructors will create. During that week’s class, the instructors will give each teacher a “trouble card” that plagues their lessons with technical difficulties (troubles will be individualized so as to disable the delivery of each teacher’s lesson). In response, teachers must create contingency plans (e.g., handouts, library research of print materials) for their lessons. In the unit’s final week, Week Seven, teachers will discuss their experiences and present their lesson plans and reports to the foundation.

The Graphical User Interface

Upon entering the Web-based environment, the preservice teachers will not find the menus, navigation bars or buttons typical of traditional Web sites. Instead, they will be stepping into their new offices. Materials—in the form of email and voice mail messages, letters, memos, and face-to-face meetings—that support the learning unit, will be stored in and accessed via five active zones: the computer, telephone, in-box, file cabinet, and daily planner.

The daily planner will be the main user-cueing device; the planner is the user’s to-do list. The list will remind users of the week’s important tasks, such as checking e-mail, and attending events (e.g., a lunch meeting with another teacher). A mouse-click on the appropriate active zone will open a small window and let the preservice teacher check their email, listen to voicemail messages, or investigate the contents of folders and files. The windows, which users can drag anywhere on the screen and have open simultaneously, will give users the ability to customize their work areas.

The complex design of the user interface is balanced by the authenticity of its elements. The office metaphor is not only relevant, but also familiar. Anyone who has ever read a letter, opened an email, or used an answering machine possesses the prerequisite skills for successfully navigating the interface.

From the first week of the unit to the last, the pre-service teacher will see this case-based learning environment evolve, as new scenarios and pieces of information present themselves. As a result, the interface must be flexible enough to accommodate this evolution, without forcing users to re-orient themselves each week. Just as one might save an old email or voice message
for further review, the preservice teacher will have access to items introduced in previous weeks—as well as new items—through the same five active zones.

The unit's scenarios are designed to realistically mimic a teacher's work environment, including interactions with fellow teachers, administrators, and support staff. A mixture of audio, video and HTML file formats will make these interactions seem more real. Video clips and sound will let the user experience their environment with multiple senses and as though they were witnessing them first hand.

Initial Sketch of Graphical User Interface
Timeline

The PT3 team has designed the case-based learning units, and development will commence January, 2002. The implementation of the course will begin May, 2002. A survey, the Stages of Concern Questionnaire (SOCQ) will assist the team in gathering data about the courses’ effectiveness. The SOCQ measures how concerns about different innovations—in our case, technology integration—change over time (Horde & Hall, 2001). Currently, students are administered the SOCQ in both the 200- and 300-level courses, and, after implementation, the team will continue to administer the SOCQ several times throughout the course. The team will also analyze student projects as qualitative data that will indicate whether the case-based learning unit is effective in meeting instructional objectives.

With the importance of training teachers to effectively integrate technology, case based methods may be one of the most powerful tools one can utilize to meet state and national standards regarding this goal. Because teacher education students often do not see effective technology integration modeled in either their student teaching experiences, or in the majority of their college courses, one class often may not be enough to present the ill defined domain of technology integration to preservice teacher candidates. This case study may prove to provide enough information to give learners a basic understanding of what technology integration not only looks like but how it can be used to solve problems and help to meet state and national education standards. Activities such as these will also add to the body of knowledge regarding the effectiveness of constructivist environments, in particular, case based learning environments.

Satellite Based Synchronous Tutorials vs. Satellite Based Asynchronous Videocassettes: Factors Affecting Students' Attitudes and Choices

Ruth Beyth-Marom and Kelly Saporta
Ruthbm@oumail.openu.ac.il

Background
The Open University of Israel (OUI) is a distance learning university. Learning is based mainly on specially written textbooks and tutorial meetings (once a week or once in three weeks) in learning centers throughout the country. Indeed, meetings with tutors at learning centers bring the university closer to the students and allow for face to face interaction between tutors and learners and among the learners themselves. However, these meetings sometimes do not materialize, as it is difficult to find enough expert tutors for all groups of students, or students are so dispersed that though many are registered for a course, there are not enough students in each region to justify hiring a tutor.

Synchronous virtual tutorials, via satellite communication, from a studio at the university to classrooms throughout the country (by the best tutor) - have been conducted during the last five years as a solution to these problems. The communication between the tutor and the students is visual, audio and data-based. The visual communication is uni-directional from the studio to the classrooms (where the tutor is seen on a big TV screen). Audio information is bi-directional (from the studio to the classrooms and from the classrooms to other classrooms and to the studio). The lecturer and the other students can hear the student who has been given the floor by the tutor. With respect to data communication, the lecturer can present multiple choice questions to the students, ask them to answer the questions by pressing an appropriate button on the satellite phone, and immediately present the distribution of answers to the students.

Seven such two-hour satellite tutorials were conducted in a "Basic Research Methods" course (for social science students) during 5 semesters. A number of factors gave rise to second thoughts about the choice of synchronous satellite tutorials as an ultimate solution: (a) only 25% of the registered students joined the tutorial sessions; (b) most students who joined the tutorials did not participate actively in the interactions initiated by the tutor or did not initiate any interaction themselves; and (c) the satellite technology has proved to be very costly.

Each satellite-based synchronous tutorial is saved on a videocassette. These cassettes can be sent to students as asynchronous tutorials. Table 1 compares satellite-based synchronous tutorials to satellite-based asynchronous tutorials delivered on videocassettes.

Table 1: Factors differentiating between satellite-based synchronous tutorials and satellite-based asynchronous videocassettes

</tbody>
</table>

In light of the above comparison and students' behavior (absences and lack of participation), we decided to study students' preferences regarding the mode of tutorials. In particular:

1. What are students' attitudes towards the tutorial modes and their dimensions (i.e., flexibility, interaction and accessibility). As can be seen from Table 1, the two types of tutorials differ in the amount of control the student has over the learning process (the first three dimensions) and in the amount of interaction between tutor and students (in the last two dimensions). Learner control is known to be associated with active learning and student-centered learning (Doherty, 1998). Interactions between students and tutor and among the students themselves is one way to increase instructional immediacy and social presence which are positively related to students' satisfaction and motivation in learning (e.g., Christophel, 1990; Swan, 2001). Will students prefer control over their learning process at the expense of losing social immediacy, or vice versa?

2. Are students' attitudes and preferences related to their learning-habits preferences? Some research has been done on the relation between cognitive styles and instructional preferences (e.g., Sadler-Smith & Riding, 1999). The present study aims to examine the relation between learning-habits preferences and instructional preferences.

3. Are students' attitudes and preferences related to demographic and academic variables? Some of our findings concerning these questions will be discussed in the next sections.
Method

Participants: Two groups of students (in the Research Methods Course) and one tutor took part in the research. Group 1: 92 students who studied during the fall semester of 2001. They had seven satellite-based synchronous tutorials (two hours each) with their tutor. Group 2: 73 students who studied during the spring semester of 2001. They had 4 satellite-based asynchronous videocassettes (based on those recorded during the previous semester) and 3 satellite-based synchronous tutorials with the same tutor.

Questionnaires: Three questionnaires were constructed -
1. Questionnaire 1: A feedback questionnaire on the satellite-based synchronous tutorials. The questionnaire included items relating to (a) attendance rate; (b) attitudes towards the tutor and the tutorials; (c) attitudes regarding the advantages and disadvantages of meeting and interacting with peers; (d) comparisons between face to face tutorials and satellite-based synchronous tutorials and (e) attitudes toward a potential asynchronous mode of tutorial via satellite-based videocassettes.
2. Questionnaire 2: A feedback questionnaire on asynchronous tutorials delivered via videocassettes. It contained items similar to those in the first questionnaire but relating to videocassettes and a comparison between three modes of tutorials: satellite-based synchronous and asynchronous, and face to face tutorials.
3. Questionnaire 3 - "How do I prefer to study?": This questionnaire contained items on four dimensions: (a) the importance of autonomy in management of learning time; (b) the importance of ease of accessibility to all learning materials; (c) the importance of synchronous interactions with the tutor (d) the importance of synchronous interactions with other students. For each of the four dimensions, a number of statements were formulated differing in the affective influence and in the cognitive influence of the dimension and the direction of that influence (positive or negative). For example, with regard to time management:
   1. When I am responsible for my pace of learning I feel I have control (positive, affective)
   2. When I am responsible for my pace of learning I feel helpless (negative, affective)
   3. My learning is more efficient when I am responsible for my pace of learning (positive, cognitive)
   4. My learning is more efficient when the timetable of the course is determined by the teaching team (negative, cognitive).

The questionnaire included 56 statements (in random order) on a Likert scale from 1 - "doesn't describe me at all" to 5 - "describes me very well".

The "How do I prefer to study?" questionnaire was administered to 288 "Research Methods" students who were not part of the experiment. Factor analysis revealed four independent factors (scales): time management (high score indicates learning autonomy), ease of accessibility to learning material (high score indicates the subject's need to "have" all material), positive aspects of interaction (high score indicates that the subject has more positive views regarding interactions - with tutor and other students) and negative aspects of interaction (high score indicates that the subject has few views regarding the negative aspects of interaction). Thus, four scores were constructed for each subject, one for each factor. There was no correlation between the scores and the following variables: gender, age and number of credits accumulated at the OUI.

Procedure: At the end of the fall semester, Questionnaire 1 (experience with seven satellite-based synchronous tutorials), and Questionnaire 3 ("How do I prefer to study?") were mailed to students in Group 1, who were asked to fill them out in that order. At the end of the spring semester, Questionnaire 1, Questionnaire 2 (experience with the four satellite-based asynchronous tutorials on videocassette) and Questionnaire 3 (in that order) were sent to students in Group 2. Forty-three (46.7%) students in Group 1 and 31 (42.7%) students in Group 2 returned the questionnaires.

Results

Group participation in learning activities: On average, Group 1 students participated in 2.9 of the seven satellite-based synchronous meetings (41.4%). Group 2 students participated on average only in 1.1 of 3 (36.7%). This difference is not significant. All students rated as high all audio and visual characteristics of the two technologies used. From reports of Group 2 students, it seems they created a learning environment at home in which others did not disturb them while they were watching the tutorial.

With regard to the activities associated with the satellite-based asynchronous videocassettes, 41.9% students reported they watched all 4 lessons, 91.7% stated they watched them only once, 56% used the back and forward option, 66.7% summarized while watching (most by stopping the video) and most of those who summarized (81.2%) indicated that they would read the summary before the final examination.

1 Contrary to intuitive perception which sees the two extreme sides of a dimension (e.g., high and low) as negatively correlated, the Psychology literature on attitudes demonstrates that often the two end points of a dimension are two independent factors (Eagly and Chaiken, 1998).
Group comparisons: Groups 1 and 2 did not differ significantly in gender (males: 58.5% and 57.6% in the two groups, respectively). Table 2 presents data comparing Groups 1 and 2 on background, academic and learning-habit preferences variables.

*Grade point average at the stage the student registered for the Research Method course

There were no significant differences between the two groups in none of the background, academic and learning-habits preferences variables presented in Table 2. Both groups were also similar in the learning materials they received (the same books and tutorials) and the tutor teaching them. As all these variables were controlled they cannot be considered an alternative explanation for any reported results (in the next sections) concerning the differences in the students' attitudes towards the different learning technologies used and their preferences (The Institute for Higher Education Policy, 1999).

Groups 1 and 2 evaluated the tutor and the satellite-based synchronous tutorials. Students were asked about the tutor's expertise, teaching pace, attentiveness to students, ability to excite interest and to clarify the material as well as command of the technology. They were also asked to rate the synchronous tutorials on a number of dimensions (how significant, interesting and organized they were, as well as the extent to which they contributed). On average, the tutor and the satellite-based synchronous tutorials were rated high (3-5 on a 1-5 scale) with no significant differences between Group 1 and Group 2. Group 2 students were asked to evaluate in a similar manner the tutor and the satellite-based asynchronous videocassettes (not including questions regarding the tutor's attentiveness to students and command of technology which were not relevant in the asynchronous mode of tutorials). Students' ratings of the tutor and the tutorials of the synchronous tutorials were compared to their ratings of asynchronous videocassettes (t test for dependent variables). No significant differences were detected. Thus, when the same tutor gives the same tutorials to similar students, the evaluations of the tutor and the lessons are independent of the technology used.

Attitudes toward interaction components: In both groups, subjects were asked whether the tutor devoted enough time to interaction with students. With regard to the synchronous tutorials, 73% of students were satisfied with the amount of interaction (no significant difference between the groups). Students in group 2 were asked the same question twice - once for the synchronous lessons and once for the asynchronous lessons. Most students indicated there was enough time allocated to interactions in both types of tutorials and the difference in response to the two questions was not significant. Most students in both groups (82.7%) indicated they participate less in synchronous satellite tutorials than in face-to-face tutorials. Table 3 describes the results concerning interaction components in the satellite-based synchronous tutorials in Groups 1 and 2.

None of the differences is significant, indicating that the **having less satellite-based synchronous tutorials** (3 instead of 7) doesn't affect students' attitudes regarding the interaction components of those tutorials.

Table 4 compares students' attitudes towards the interaction components of satellite-based synchronous tutorials to those components in the satellite-based asynchronous videocassettes. The numbers given to questions in Table 4 are similar to those in Table 3. None of the differences (for identical or for similar questions) were significant (t tests for two dependent variables).

The results in Table 5 strengthen the validity of the learning-habit preferences questionnaire. Students with a high score on the positive interaction factor (the subject holds more positive views regarding interactions - with tutor and students) believe more than others in the social contribution of other students and in their learning contribution. Students with a high score on the negative interaction factor (the subject holds few views regarding the negative aspects of interaction) perceive students' interactions in class as less disturbing.

Preferences of different learning technologies: Subjects in both groups were asked the following question: "Below are two types of tutorials with which you are acquainted: face-to-face tutorials and satellite-based classroom tutorials. On the assumption that the same tutor teaches the tutorials, mark with an X the method that you believe is the best way of learning with respect to the dimensions below". The 11 dimensions listed were: I understand the tutor better; I concentrate better; It is easier for me to summarize the tutorial; I ask more questions; I answer more questions; I enjoy the lesson more; I understand the material better; The questions I ask get more responses; I feel that I have better control of the situation; I feel more obligated to attend the tutorial; I prepare myself better for the tutorial. For each dimension, the proportion of face-to-face choices was calculated (for each group) and a Chi-Square test for two independent groups was performed to identify differences. None of the results were significant, thus reinforcing the conclusion that having fewer satellite-based synchronous tutorials does not affect students' attitudes towards this type of teaching/learning. Face-to-face tutorials are considered advantageous with respect to ten of the eleven cognitive and affective dimensions (for most dimensions, face-to-face tutorials were chosen by more than 70% of the students). On the last dimension (I prepare myself better for the tutorial), only 48% of Group 1 and 66.7% of Group 2 chose the face-to-face tutorial as better.

Group 2 students were asked a similar question with the same dimensions and an additional five (I remember more; It is more convenient; I prepare a written summary; I control my learning pace; Overall) concerning the choice between face-to-face tutorials, satellite-based synchronous tutorials and satellite-based asynchronous videocassettes. For most dimensions (except for "It is more convenient" and "I control my learning pace"), most students chose face-to-face tutorials. Satellite-based asynchronous videocassettes over rode the other two types of tutorials for all other students. 51.9% and 77.8% of students chose satellite-based asynchronous videocassettes when asked about convenience and control, respectively. When asked to make an overall choice between satellite based synchronous tutorials and satellite based asynchronous videocassettes, 60.7% chose the asynchronous mode and only 32.1% chose the synchronous mode.

Group 1 students were also asked about a hypothetical choice between satellite based synchronous tutorials and satellite based asynchronous videocassettes (hypothetical, as they didn't experience the second option). On most dimensions, the dominant choice was satellite based asynchronous videocassettes (except for "I am more involved in the learning process" and "I am more active"). When asked to make an overall choice between the two, 76.3% chose the asynchronous mode and only 23.7% chose the synchronous mode.

Individual differences in the choice of learning technologies: Do learning-habit preferences, as measured in our questionnaire, correlate with students' choices of different types of tutorials? Students in both groups were divided according to their overall choice between the satellite based synchronous tutorials and the satellite based asynchronous videocassettes. The two groups were compared on the 4 learning-habit preferences scores. Table 6 presents those comparisons.

Table 6: Differences in learning-habit preferences between students who chose satellite based synchronous tutorial and students who chose satellite based asynchronous videocassettes.

</tbody>
</table>
The two groups of subjects differ in 3 of the 4 learning habit preferences scores. Those who chose the satellite-based synchronous tutorials were significantly higher on Scale 3 (believing in the positive aspects of interactions) and significantly lower on scales 1 (learning autonomy) and scale 2 (the need to "have" all the material).

Discussion and Conclusions
When choosing between face-to-face tutorials and satellite based-synchronous tutorials, most students prefer the former, replicating a previous study done at the OUI (Beyth-Marom et al., 2000). However, when choosing between satellite based-synchronous tutorials and satellite-based asynchronous videocassettes, two thirds of subjects prefer the latter. As in the previous study done at the OUI, most students prefer flexibility and control of their learning processes while studying at home with less social immediacy (with videocassettes) over the social immediacy they have (but less personal control) in synchronous satellite based tutorials.

In an effort to study the factors affecting students' choices and preferences, students were asked about their attitudes towards different interaction components. In both groups, students did not rate the interaction components (synchronous or asynchronous) as very important or contributing. All students answered a questionnaire about their learning-habit preferences. Students with a high score on the positive interaction factor (the subject holds more positive views regarding interactions with tutor and students) believe more than others in the social contribution of other students and in their learning contribution. Students with a high score on the negative interaction factor (the subject holds few views regarding the negative aspects of interaction) perceive students' interactions in class as less disturbing.

Students who preferred the satellite-based synchronous tutorials were compared to those who preferred the satellite-based asynchronous videocassettes on the 4 scales of the learning-habit preferences questionnaire. Those who preferred the synchronous tutorial were significantly higher in their belief in the positive aspects of interactions (Scale 3) and significantly lower on learning autonomy (Scale 1) and the need to "have" all material (Scale 2) than those who preferred the asynchronous mode.

In general, students' tutorial-mode preferences depend on their learning-habits preferences as measured on a Likert type questionnaire: their attitudes toward the control of learning and the possible contribution of interactions.

Abstract: Twenty-four Teaching, Technology, and Teamwork (TTT) projects sponsored by the Charles E. Culpeper Foundation at California Lutheran University were developed from Fall 1999 through Spring 2001. This project update reviews strategies used in this team-based model. Trends in project development and evaluation findings will also be reported.

This paper presents findings from the Teaching, Technology, and Teamwork (TTT) program sponsored by the Charles E. Culpeper Foundation at California Lutheran University. CLU’s Information Technology Advisory Committee (ITAC) solicited and reviewed faculty proposals. Faculty whose proposals were accepted met with their team members once a week for one semester to develop their projects. Each project team included a faculty member (the content expert), a reference librarian (the information specialist who helped with research), an educational technologist, and a student assistant who implemented the technology elements of the project.

The projects used combinations of five major technologies. WebCT projects (14) outnumbered slide digitization and database development (2) and video production (7); custom web sites (6), and CD-ROM’s (1). The total student development time in hours was greatest for video (840 hours) followed by slide digitization (750 hours). The fourteen WebCT projects required 560 student development hours followed by the custom web projects with 240 student hours. The digital video and slide projects are not scaleable; WebCT, with its difficult user interface, appears to be scaleable.

One course used the EduCue system to incorporate problem-based learning in the classroom. Students submitted answers via hand-held devices and the instructor’s computer tabulated and displayed their responses. Students discussed the results and used the EduCue device to answer the same questions again. Because each of the devices
has an ID number, the instructor knows who attended class and how each student performed. (For more information on EduCue, see http://www.educue.com.)

Some of the most successful projects have multiple audiences. Our California history project has been used by four audiences: pre-service teachers who will teach California history; fourth grade history teachers; students in CLU's California history class; and Computer Science students who are learning programming. A marine biology professor's Beneath the Surface Catalina Island video is used: by CLU students preparing for a Catalina Island field trip; and by passengers who visit Catalina Island on The Rapture—a marine biology expedition and research boat. Faculty and students use a WebCT “course” on Service Learning. (For more information on these projects and the Culpeper projects, see: http://www.clunetedu/TLC.) Our assessment of the TTT program included formative and summative evaluation. Our campus computing committee reviewed and critiqued projects at midcourse. In May 2001, we collected evaluation data on the Culpeper project via an on-line survey form using AAHE's Project Flashlight program. Fourteen of 24 faculty responded to the survey. We collected additional data from focused interviews with program participants during Fall 2001.

CLU’s proposal to the Charles E. Culpeper foundation suggested that faculty lacked the time and expertise to extend their most successful pedagogies to include technology. Providing summer stipends or one course release during the year helped solve this problem. Half of the survey respondents commented on the importance of the teamwork component. For most, the experience of collaborating with a supportive team was very useful.

Not all faculty, however, embraced the team approach. One respondent commented, “Don't force the "team" aspect on everyone—provide the parts of the team that are helpful (for each case), and then get out of the way!” Several respondents mentioned problems with the students on the teams. The quality of student help in completing the project varied considerably. One faculty member observed, “Much was accomplished when I had good help working on the project. Things languished when I didn't.” During the initial development cycle, student help was not screened as closely as it needed to be, and this was corrected. The development teams with technically competent and responsible student assistants usually resulted in a higher quality product. When the faculty member seemed to be in the program for the money or to teach one less class, progress was slow or the final product weak. In a couple of cases, these faculty resisted any organizational and planning meetings, something we felt was critical to getting the projects started and developed in a timely manner.

Some faculty reported new ways of envisioning how to teach. “Actually, the Culpepper project (Thespian Survivor) … did force me to think differently, perhaps in more visual terms, about how to present the same material I had used in class for the last few years.” Several slide and video projects were completed, and one faculty member commented that his project provided the “chance to better grasp the possibilities of how my images can be used more easily and (hopefully) more creatively in my teaching.”

For faculty who do not understand technology, the problems surfaced during implementation in the classroom. When a faculty member would make the time to work with the team in the classroom prior to implementation, there were fewer problems. Media Services also provided technical assistance for some of the initial class sessions in case there were problems.

Post-project evaluations demonstrated that implementation of their online projects prompted faculty to envision new and more effective ways to teach and that they had observed improved student learning. Some also reported, however, that in order to enhance and quantify these improvements, new assessment strategies need to be identified and incorporated into subsequent versions of the projects. Other evidence of the Culpeper program’s success can be found in: the fact that the University is funding the Teaching and Learning Center and its two new positions; and the dramatic increase in requests for and the availability of technology facilities.
An Empirical Evaluation of Sonar Courseware Developed with Intelligent Tutoring Software (InTrain™) at Naval Submarine School

Abstract: With limits on both personnel and time available to conduct effective instruction, the decision is being made increasingly to enhance instructor-led courses with Computer-Based Training (CBT). The effectiveness of this conversion is often unknown and in many cases empirical evaluations are never conducted. This paper describes and discusses the evaluation and effectiveness of adaptive courseware authoring and utilization in the context of the Submarine Officer Basic Course (SOBC) at the Naval Submarine School, Groton, CT.

Introduction

The Naval Submarine School (NAVSUBSCOL), the “Center of Excellence” for Submarine Warfare Training, has recently dedicated a new, state-of-the-art electronic training facility that hosts ten Advanced Electronic Classrooms (AEC), a building-wide enterprise Classified LAN (CLAN), and external high bandwidth connectivity. The NAVSUBSCOL Officer Training Department provides the Fleet with Prospective Commanding Officers (PCOs), Prospective Executive Officers (PXOs), Department Heads, Division Officers, and a host of officer billet and specialty training courses. NAVSUBSCOL training responsibilities range from engineering, damage control, and ship control, to combat training simulation and tactical employment of the submarine. Currently, the curricula are based primarily on instructor-led presentations and practical exercises in lab/simulator environments.

Recently, NAVSUBSCOL determined that the demand for training was outpacing the available resources (instructor-led presentations and practical exercises). To address the situation, NAVSUBSCOL searched for a supplement to the instructor-led training by adding computer-based training (CBT). The goal was to leverage the available resources of the lead instructors while incorporating additional benefits of current courseware, maintaining internal control of content, and reduce staff loading.

This case study discusses the efforts made at NAVSUBSCOL to integrate CBT into the curriculum and the effects this type of learning will have on learning outcomes. Through a comparison study of both CBT and instructor-led courseware, supportive evidence can be garnered that support a savings in development time and improvements in test scores.

Traditional multimedia instruction creates an engaging learning environment in which multiple sensory pathways convey information to the student. NAVSUBSCOL wanted to choose an authoring tool that would allow instructors to re-use content and learning objectives throughout multiple courses, while
delivering individualized instruction to a large volume of students. Likewise, it wanted the authoring tool to be easy to use and require low developmental times due to constant turnover of personnel.

InTrainTM provides such a tool. InTrain instruction builds and tailors the content and form of instruction to the moment-to-moment needs of the student. This results in faster acquisition and longer retention than is seen with conventional learning approaches.

In a marked contrast to conventional CBT, InTrain develops an individual education plan (IEP) for each student and makes its instructional decisions at run-time. Students proceed when they demonstrate that they are meeting the goals of instruction mastery. Students who need more time or different methods to reach the same level of performance receive the instruction they need.

While forming an IEP, InTrain considers information about the student (e.g., the student's mastery profile and instructional history) and about the goals of the curriculum (i.e., which objectives must the student meet at what level of proficiency). The IEP describes the order in which the system will introduce new topics and the training techniques that will support the introduction. When assessment is needed (both pre- and post-tests may be used), InTrain randomly selects among the assessment options (e.g., test questions) associated with the learning objectives under investigation. Similarly, when InTrain wants to present instruction, it selects among the instructional options associated with the target learning objectives. Instruction and assessment continue until the student has adequately mastered all of the required learning objectives.

Shorter development times are also addressed by the InTrain Author! software (InTrain Author! is the interface through which InTrain courseware is authored. InTrain does not require any programming experience and offers an "as you go" tutorial on content development. This ease of use allows for shorter development time and less “training” time for new courseware development.

Method

To assess the effectiveness of the training to be demonstrated, Sonalysts, Inc. conducted a study in conjunction with NAVSUBSCOL. Traditional instructor-led classroom students were given 8.5 hours of instruction about SONAR, as were the CBT students. The learning objectives and goals of the content presented to each group was the same. In contrast, another group of students received InTrain instruction. Both groups were given the same amount of time to interact with the content.

After the second group completed the curriculum, both groups were then given a final written examination, comprising of 80 questions. Instructors scored the tests that included multiple-choice and true/false questions. The students needed to achieve a minimum of 70% to pass the course. The scores of the instructor-led group, were in-line with historical, satisfactory averages for this content and type of instruction.

Traditionally, training for the NAVSUBSCOL has taken place in instructor-led classrooms. Each classroom comprises approximately 24 students, who spend a portion of a 10-week course learning passive sonar theory and underwater acoustics. The focus of the comparison is on a specific 8.5 hours of the Sonar curriculum taught during the ten-week course. The 8.5 hours of instruction cover the following courses: Passive Sonar Equation, Total Background Noise, Beamforming, Figure of Merit, Source Level, and Propagation Loss.

While each course has a standardized set of Learning Objectives and a Curriculum Outline, each is modified accordingly. Courseware for traditional instruction has usually been developed in PowerPoint lessons with Instructor Discussion Points and Lessons Learned being conveyed by each instructor. PowerPoint are inherited by the previous lesson instructor and amended when the need occurs.

Students are scheduled for each of the above topics based on numbers of students, classroom availability, and instructor availability. Delivery time for each course is a pre-defined amount and scheduled by a central person. Students are assigned to the next course as they move through the curriculum. At the end of each component of instruction (sonar, tactics, plots, etc.) students are given a test comprising 80 questions.

In contrast to traditional methods, CBT was developed. To address NAVSUBSCOL’s goal of authoring CBT “in house,” Submarine School staff instructors, working with guidance from instructional designers and subject matter experts from Sonalysts, utilized InTrain AUTHOR! to develop an eight-hour, adaptive CBT course on the passive sonar theory equation, theories, and underwater acoustics. This development effort was a multi-stage process. Initially instructors were given a basic INTRO courses in
courseware development and creating computer-based training. Instruction focused on creating and decomposing learning objectives, creating assessment items, and developing content (at a variety of targeted levels). Ultimately, one instructor became responsible for development of 8.5 hours of SONAR courses. InTrain allows for instructional method neutrality. The tool does not require one to build/create Sharable Content Objects/presentations in a particular manner, thereby allowing the developer complete freedom in content presentation and delivery. Sonalysts served as “consultants” to the instructor in charge of development. Media was reused from courseware previously authored for other topics, instructor-led training, and Submarine Officer On-Board Training (SOBT) courses.

The content developed using InTrain, was delivered to a class of 21 students that utilized the courseware during two four-hour dedicated periods, plus a one-hour wrap-up following the testing. The courseware was parsed into six topics that mimicked the training methodology of the material in instructor-led instruction. The CBT was deployed using options that permitted the student to learn the material and demonstrate mastery through assessment. Students were permitted two attempts at the assessments. If the student failed a second assessment, an instructor-led remediation was conducted.

Students were given the same amount of time to learn using the computer-based course as they were given to learn through the traditional methods. The reasons for this were two-fold: 1) Delivery of CBT was an emerging concept within NAVSUBSCOL. While computer-based training is available, the courses are self-paced auxiliary learning on Lessons Learned and Practice for defined skills. There was no model from which to build time/scheduling differences around this type of learning. 2) The SOAC/SOBC Associate Assistant Director of Officer Training maintained that it was important that an appropriate amount of time was scheduled for students to receive the training. The most efficient manner to achieve this was to “schedule” it in the same blocks of time as the traditional methods of delivery.

Upon completion of the material, students were able to review/return to the material at their convenience for follow-on study.

There were four measures by which results were garnered for this comparison study: Survey, Test, Historical Averages, and Development Time.

Survey – At the conclusion of the computer-based instruction (InTrain Author!), students and instructors were given a Level 1 evaluation. This survey consisted of both open-ended questions and Likert-scale questions.

Test – The paper-based test included 80 questions that were both multiple-choice and true/false. Both groups of students (CBT and instructor-led) were given the same test and graded using the same set of instructors.

Historical Averages – The historical averages used in the study are the averages of students who had gone through the instructor-led training in the past two years. The scores were from a slightly revised version of the test given to these students (The revision included the learning objectives but a few questions were changed).

Development Time – Development time for the InTrain course was measured.

Results

The results of both courseware development and actual “testing” of the courseware as indicated below show improved in results in both the authoring content and the student performance.

Survey

The results of the students’ survey were interesting. A 5-point Likert scale was used for the 20 questions.

The areas that scored highest (4–4.5) were the presentation of the material and the way in which students interacted with the course. A score of 4.2 was given to the overall usefulness of the course within the curriculum in general.

The students’ response to another set of questions (scoring 2.6–2.9) demonstrated that no additional instruction or assessment was necessary, lending credibility to the individualized component of the training which provides “just enough” instruction to achieve mastery of the learning objective. There were enough assessment and instruction to teach the topic without being overwhelmed by obscure
materials. This method targets the learner to specific information to support specific concepts and objectives.

**Test Results**

Students' scores in both the instructor-led group and the InTrain group were measured and compared on the basis of results from the 80-question test.

**Courseware Development**

No metrics exist to gauge the amount of development time required to prepare instructor-led courseware because the instructor-led materials are inherited from the original instructor and revised over several years.

Although CBT development ratios can vary widely, actual development time was compared to a benchmark of 200 hours per hour of CBT. For this effort, that would yield an approximate effort of 1600 hours of authoring time to design, storyboard, implement, and test the course.

In contrast to this benchmark, the Submarine School staff spent a total of 500 hours for the development effort. Sonalysts' instructional designers and subject matter experts spent an additional 150 hours providing feedback and guidance on effective CBT design and content presentation.

**Discussion**

The survey results yielded some interesting information. The open-ended questions asked throughout the survey indicated that the students were favorably impressed with and receptive to the CBT that was presented. Additionally, they liked the "individualized instruction" that was presented through InTrain allowing some of the students to finish quicker and more efficiently than others who required more time or instructor intervention. Some negative responses about the CBT included the need to have an instructor review session at the conclusion of training (before the test). Another negative comment was the length of time dedicated to each training session (taught via CBT) was too long. In both cases each comment can be resolved in a simple and effective manner.

NAVEDTRA 131 (Task Based Instruction), the controlling doctrine for the course in question, requires that all instruction that results in a bottleneck be serially scheduled. That means, for a class of 12 students participating in a learning experience that takes 4 hours and has capacity for only 6 students, an entire training day must be scheduled against it. By its nature, CBT provides unparalleled flexibility to obviate bottleneck scheduling. Students learn at their own pace, on their own schedule. In an instant example, the other six students not in the learning experience can complete assigned CBT required for another part of the course. The time saved by removing bottleneck scheduling is approximately 24 hours.

If given proper integration into the NAVSUBSCOL curriculum scheduling process, students would proceed through the courses on an individualized basis. In fact, they would be assigned courses and
a completion date and proceed at their own pace toward that completion date. This is the way that NAVSUBSCOL is moving with the integration of a Learning Management System (LMS) to create such assignments.

More CBT is undergoing development in other areas of the 10-week curriculum matrix. When more of the courses are converted to CBT and an entire curriculum can address scheduling, changes will be easier to implement. When timesaving is realized, an instructor-led review session can be addressed and implemented to quantify knowledge gained through the CBT.

Additionally, the study yielded anecdotal evidence that four hour training periods for the students were too long and resulted in student "burn-out," an assertion supported by student feedback following the training. A consensus of input suggests that a period of two hours at any given time/topic is the longest that should be scheduled. The artificiality introduced by the beta test (i.e., the test dictated two four-hour periods of study) required the student not study when they were ready to, but rather when the test required it. As such, student mastery and navigation through the material suffered at the end of the first training period due to student fatigue.

Finally, we address test scores. We can see that the scores on the test were higher for the InTrain classes than the traditional instructor-led method. Since both groups were achieving at a high-level, the observed results might actually understate the size or effect one would expect in other settings. Another factor that influenced the “ceiling effect” introduced by these scores is the high average among the students. If the tests were longer and students had been scoring in the 70%, we would have expected to see an even greater range of effectiveness defined.

CBT Benefits

The CBT in question does provide some benefits when measuring interaction time metrics: In the study, the students required an average of 8.2 hours to complete the 6 topics in the CBT. In comparison, instructors require 8.5 hours to teach the same material in an instructor-led lecture format. One would assume that the CBT seat time would be reduced about 50-60%. However, given the restrictions of the imposed time schedule this was not seen. One would assume that the deployment time would be less once a new scheduling system is implemented and appropriate time values are added to the scheduling matrix to accommodate Computer-Based Courses.

Additionally, there was a time-savings in terms of instructor remediation time. A total of 7 students required remediation by an instructor, yielding a total of approximately 1.5 man-hours of instructor time for student instruction (vice the nominal 8.5 hours required to teach the material plus any time spent in individual tutoring). For the beta test, Submarine School instructors attended all training sessions, but it is envisioned that once CBT is well entrenched in the SOBC curriculum and students understand how to use it, direct instructor supervision will not be required. Rather, CBT will be employed to teach basic theory and concepts, and instructor led seminars synthesizing material and covering more advanced concepts will be used to periodically ensure students have satisfactorily advanced through the material.

On its face, the integration of Sonalysts’ tool represents a 59.3% savings in development time over a typical CBT effort. However, some elements in the study influence this apparent savings:

- The Topic Learning Objectives derived from course Personal Performance Profiles (PPP) tables already existed; hence the course was not built “from scratch.”
- The Submarine School staff author had no training in CBT development. While this is a de rigueur requirement for any authoring tool fielded for Submarine School, it is also true that those same personnel will become more proficient in the use of the tool as more CBT is authored.
- A limited amount of media (3 graphics) was produced in support of this effort. For the remaining approximately 700 graphics and animations used, existing media and or local generation tools were leveraged for the media production. It is anticipated that during a typical CBT authoring effort, the existing media bank will not be quite as well populated.
- The purpose of the study was also to test InTrain AUTHOR! Several software problems were identified and corrected during the test. This resulted in an aggregate reduction in authoring capability for a period of about one week. InTrain has completed Beta testing and made changes, so this type of delay should no longer occur.

210
Conclusions

The entire authoring effort, deployment of the course, and post-CBT analysis spanned 3.5 months. Sonalysts, provided the IT, instructional design, and subject matter expertise in an effort to investigate the usefulness of InTrain CBT in an established, structured U.S. Navy curriculum. Submarine School provided exceptional dedication to the effort, including the combined work of the CBT author and testing team.

The InTrain CBT test provided valuable input to the product developers at Sonalysts, both in terms of performance and study recommendations. As part of the implementation of distance learning efforts at NAVSUBSCOL, Sonalysts will be involved with the integration of the submarine officer training curricula into the THINQ™ LMS (Training Server). This initial testing allowed the software engineering staff at Sonalysts to evaluate the requirements and use patterns of CBT (and specifically InTrain) in an enterprise LAN environment.

As part of the population of the LMS with content, Submarine School must develop and deploy a robust web-hosted CBT course structure to allow remote users access to training prerequisites and remediation to support both professional development and continuing training onboard submarines. This test provided the Submarine School staff some experience in CBT design and provided some metrics and recommendations about implementing CBT to maximize its benefits to the student population.

Summary

Based on student performance and feedback received, the following conclusions can be drawn from the test:

- The benefits of implementing adaptive CBT in the Submarine School range from possible timesavings in specific curricula to automated remediation and instruction. Manpower savings will permit Submarine School to pursue implementation of a Distance Learning support division comprised of experienced subject matter experts who have instructional expertise in front of a class and as CBT authors.
- CBT cannot replace the instructor completely. Students asserted uniformly that the face-to-face communications were at times critical for the understanding of particularly complex concepts. While not applicable to the material delivery in the Beta test, NAVSUBSCOL is planning on maintaining some instructor-led seminars to provide higher-level synthesis of read material.
- Training via CBT provides exceptional flexibility to both the schoolhouse (in terms of resource scheduling) and to the student (to learn at his convenience).
- The potential to improve training efficiencies, effectiveness, and achieve Fleet readiness improvements with the infusion of advanced training methodology and technology is enormous and clearly measurable. This effort is not envisioned to replace the resident training experience but to enhance the level of professional development that can be achieved and to provide continuous training and maintenance of readiness to students and groups ashore or at sea. A substantial commitment to investing in information technology infrastructure has been made, but the return on investment will not be realized without a concomitant fielding of advanced learning methodology products. It is recognized that this vision in its many forms and variations cannot be achieved immediately; the first small steps will reflect changes in technology and processes.

---

1 Historical averages are based on exam results from the last year.
2 The written examination included two topics that were not developed into CBT but were presented to the students in traditional lecture format. The average for those two questions was 79%. A corrected average for performance on just the InTrain instructed material was 96.2%. Removal of these two topics from the other tests did not change the historical or last 4 class means in any significant fashion (± 0.2%).
3 Exam failures are counted in the student mean as 70%. Remediation and re-exam are conducted upon exam failure.
Collaborative Integrated Applications for Mathematics and Science Content and Pedagogy Among University Faculty and Public Schools

El Paso, Texas is a border community with a population of over two million people. The city is the fifth poorest city in the United States with a minority (Hispanic) population of about 78%. A collaborative effort among the Colleges of Science and Education and Public Schools was sponsored by the National Science Foundation (NSF) to improve mathematics and science education. This paper concludes the study of a six-year project. The goals of the project were:

1. To develop a working collaboration among Colleges of Science and Education and Public Schools
2. To improve pedagogical applications with content faculty and to increase content knowledge with pedagogical faculty
3. To bridge the gap between university theoretical learning and real world practice in classrooms
4. To develop a model of teaching that produces teachers capable of teaching mathematics and science to "high risk" students

No one would argue the need for teachers to know their content but content alone does not produce the results needed for all students to learn. This paper outlines a four step model of teacher training based on theories of Vygotsky and Piaget and the research resulting from the Partners for Excellence in Teacher Education (PETE), an NSF initiative project. The basic model is as follows.

Faculty from the Colleges of Science and Education team-teach integrated courses on-site in public schools. The courses are 1. Block I, The Property of Real Numbers, Curriculum, and Mathematics Pedagogy: 2. Block II, Physical Science and Science Pedagogy. The university classes are taught in schools and the Block Classes include a teaching segment in which the university students go directly from class to a classroom to practice teaching the university content using the pedagogy. University faculty and public school
teachers provide immediate and written feedback concerning the teaching segment.

PETE was funded in 1996 to investigate ways to improve mathematics and science teaching in the United States. The first step was to develop trust and respect between faculty in the Colleges of Science and Education. Many hours were spent discussing theoretical and conceptual beliefs concerning learning. Major differences in the culture of these colleges were discovered concerning learning and teaching. Faculty worked to identify common ground, agree on theoretical approaches to learning, and determine plans to combine courses and implement an experimental approach to teacher training. The science pedagogy course moved to the school site in 1997. Three semesters later the Physics department joined the pedagogy course with the integrated Block course. Based on the success of this project the mathematical block united and moved to a school the next semester.

Multiple evaluation has been used during the course of the experiment. Content pre- and post- tests, attitudal surveys, video analysis of teaching tapes from actual classrooms, and cognitive interviews have been compiled and analyzed. ExCET test (the Texas qualifying exam for teachers) scores have been compared.

Implications could include a new model for training teachers, identifying the process for successful collaborations, and a research design for teacher assessment. Further studies of this model will be expanded to other classes at UTEP and need to be replicated at other sites.
Awareness and Cohesion as Key Factors for Interaction - Lessons Learned from the VFH

Gerold Blakowski
University of Applied Sciences Stralsund
Germany
gerold.blakowski@fh-stralsund.de

Udo Hinze
University of Applied Sciences Stralsund
Germany
udo.hinze@fh-stralsund.de

Introduction

The federal flagship project "Virtual University of Applied Sciences for Technology, Computer Sciences and Business Administration" (VFH) predominantly employs “virtual” teaching methods which require a high level of interaction. Spontaneous, informal communication is emphasized, and is indeed necessary for Computer Supported Cooperative Learning (CSCL). Also, a “virtual community” is to be formed in which students can improve their communication skills. Awareness and cohesion are essential for both, CSCL and the virtual community, and their importance in communication will be explored, conceptualised and specified. We show the status quo and possibilities for optimisation, by means of the evaluation results of the pilot phases of the VFH.

Requests

Didactic requirements of the VFH are fulfilled through new and innovative learning forms. These forms, especially CSCL, require a sufficient level of interaction (i.e. cooperation, communication, coordination). Also, the cohesion of the group and, fundamentally the conscious awareness of other group members are important.

Group-cohesion and awareness are not only relevant for the CSCL-process. Cooperative processes in the VFH should not be limited to the syllabus. Under the view of lifelong learning, it is essential to support self-organised learning methods within the framework of the VFH. An example is a learning group in which students prepare for their exams. In such groups informal and spontaneous interaction is needed.

Communication without a mentor where students ‘chat’ about predetermined subjects is of paramount importance to the development of the VFH to a virtual community. Rheingold defines a virtual community as "social aggregations that emerge from the Internet when enough people carry on public discussions long enough and with sufficient human feeling to form webs of personal relationships in cyberspace" (Rheingold 2000). This should also pertain to the VFH. Without sufficient interaction the VFH remains a largely anonymous learning environment.

Cohesion

The quality and quantity of cooperation depends on the amount of cohesion occurring between those cooperating. This cohesion or commitment does not guarantee a better performance. Nevertheless, intense social cohesion within a group is a great motivating factor. Group members positively perceive this cohesion, and they behave in a “group-sense”. The social cohesion perspective focuses on the fact that students want one another to succeed, and that is why they help one another in the learning process. The usual sanctions controls of a fixed-group norm can be partially avoided. The intensity of group-cohesion is dependent on a multiplicity of factors, like awareness, possibilities of interaction, task, group size, homogeneity, individual factors and time of cooperation.
But the explanation of the learning matter relates only slightly, or has no impact at all on the learning success of the recipient. The advantages lie rather clearly on the person who gives the explanations.

Thus, a structure needs to be created which makes explanation possible for all group members—indeed from group status and individual competence. Within this context the main starting point is the creation of the task. If designed as a jigsaw, one can assume that explanatory processes, independent from the status, are to be stimulated.

**Awareness**

In order to develop social obligations and responsibilities within group cohesion, interaction must be promoted. The basis for interaction is perception of the participants as well as their actions. This "awareness" is fundamentally essential for effective performance in virtual groups.

Briefly viewed, awareness enables "the individual to group the situation of his/her current surroundings, and to accordingly adjust his/her actions" (Pankoke-Babatz 1998). In the area of CSCL, this means that one must be aware, even in an "electronic" surrounding, of various alterations in the atmosphere, its causes and effects, the actions of others and their effect, and other events occurring. Awareness is summarized as "an understanding of the activities of the others as a context for its own activities" (Dourish & Belotti 1992), or more succinctly "knowing what is going on" (Endsley 1995).

What is essential for the spontaneous, informal interaction and for cohesion? Primary is personal awareness that refers to a person. This comprises synchronous and asynchronous awareness information. Asynchronous awareness information is attainable for example through a homepage of the participants. Synchronous awareness information can be sub-divided. One essential aspect is the transmission of attention focus, e.g. usage of a telepointer on a shared whiteboard enables participants to follow others actions. The other aspect is the ability to facilitate contact. An example is the information about the availability of the participants in the learning environment.

An evaluation result of the pilot phase of the VFH was, that the main problem for groups was the lack of synchronous awareness information especially the missing ease of making contacts. The following remarks were expressed: "I can't get into the work if I don't know who's sitting on the other end of the computer." The result was a preponderant asynchronous communication. The students were unhappy about "being reliant, that the others constantly check E-mails, news or discussions. There is no 'wake up' alarm per telephone". The lack of contact and the altogether defective personal awareness spawned the following remark: "if the technical and personal working conditions aren't clarified, there is scarcely a chance to cooperate."

Spontaneous communication, which is an important success factor of CSCL and the establishment of a virtual community in the VFH is not possible in the framework of externally scheduled 'Chats' and with a learning space that provides asynchronous group communication but insufficient awareness support. Spontaneous contacts and communication must be improved. This requires, in addition to general didactical reflections, advanced support for awareness, especially personal awareness.

A Delivery Server Infrastructure for Multimedia Distance Learning Services

Andrea Bör
Institute of Communication Networks
Munich University of Technology, Germany
Andrea.Boer@ei.tum.de

Abstract: The distribution of content and applications over the Internet is one of the most demanding research topics. One challenge is to present and manage interactive multimedia services in different networks hosted on various servers with diverse operation systems and miscellaneous system configurations and conditions. In this paper, we present a delivery server infrastructure for sophisticated multimedia content. Comparable with the Application Service Providing concept, we introduce a platform independent framework to provide interactive distance learning services. The aspects of scalability and load balancing are a main part of this approach and will be treated respectively. High availability and security are also mentioned.

Introduction and Motivation

On the threshold of the information society to the knowledge community the learning and training habits have to be transformed to meet future challenges. Not only the implementation of new learning methods in traditional learning environments but also the necessity for lifelong learning increases the relevance of new information technologies for teaching and learning issues. In this context, several projects at the Institute of Communication Networks at the Munich University of Technology (Germany) deal with the development of new techniques. One emphasis is the implementation of the infrastructure because the supply of services via networks is becoming more and more important.

There is a lot of work going on in the area of Application Service Providing (ASP) and Content Management (CM). Other institutes and laboratories are doing research, and diverse companies offer their hardware or software solutions. A good overview of the roles and issues of ASP is described by [Durlacher Research (1999)] including some economical aspects. About content and knowledge management there are a multitude of sources in the Internet, see also "Contentworld" (www.contentmanagement.com).

From the technical point of view, we differentiate between hardware and network techniques (e.g. servers, switches) offered by enterprises like Cisco Systems, Nortel Networks, Hewlett-Packard, IBM and SUN Microsystems, and software solutions and application management systems, such as Microsoft, Citrix Systems, Oracle, SAP, Lotus Development and so on.

At universities and other learning centers different sorts of Web portals have been developed, but we consider that none of them is really suitable to form a modular and flexible framework to provide interactive distance learning services, like remote simulation services. In this context, it should be noted that we do not try to compete against the solutions mentioned above by implementing another software suite. We rather suggest a new tool architecture, which allows the integration of existing components in a more flexible manner. To our knowledge none of the developments pursue this distributed and service-oriented approach. Though we consider a diversity of multimedia services, we suggest using an integrated solution of centralized server system.

Application Service Providing for Distance Learning

Also in the educational environment effective provisioning of distance learning services is an important challenge. Therefore, we first discuss what the expression "ASP" means and we point out the benefits of the ASP-concept in TeleEducation scenarios.

Application Service Providing (ASP) stands for the management and the distribution of software-based services and solutions to customers across a wide area network from a central data center. Thereby an application server is frequently viewed as part of a three-tier application, consisting of a graphical user interface server, an application server and a database. The access is done via a web browser. Thus, the user only needs a thin client to execute the software. High availability and performance of the applications and the security of the user data are some of the advantages the ASP-concept has for business management. Expense, security and reliability may be some reasons to implement this concept at universities and other learning centers. For offering content and applications for TeleEducation issues, we distinguish between three different types of learning environments in the Internet: learning portals, e.g. the National Technological University (www.ntu.edu), learning platforms (www.virtual-learning.at) and enhanced learning delivery server infrastructures.
The Delivery Server Infrastructure “KIARA”

At our institute we established a server system KIARA, which offers the features of a network portal, like search and linking functionalities (Fig. 1). The framework allows not only the ability to deliver some multimedia content but also to get access to different applications, which are hosted at the internal network computers. A main aspect of this architecture is the management system, which deals with file access, simulation demands and security requirements. Together with its billing and access right abilities, the management system presents some sort of ASP capabilities. At our institute the system is used to support simulation programs remotely for research work and educational purposes.

Further details on the hardware and basic software of the architecture are described in [Merz, Bör, 2000].

Application Management System

The outstanding benefit of the management system is its scalability. Also availability and mobility are obtained by storing relevant information in a database on the server-side. One main task of the server management is to allocate the application demands to different computers of the cluster unit for better load sharing. When the user starts to communicate with the system, the user-management checks the authentication. Subsequently, the user gets the possibility to configure the parameters for a requested application with the help of a graphical user interface (GUI) on the client-side. Afterwards, the application request is transmitted to the server. In addition to user-management the server provides a licensing system. With the help of a scheduling table, the applications can be executed in a time-controlled manner. The executions of different individual applications are distributed with the help of a load balancing system on different cluster computers for a better enhancement of computing performance. Further details about the implementation of the system are described in [Bör, Jost, 2001].

Conclusion

In this paper, we present a delivery server infrastructure, which supports not only standard ASP-software, but also other types of interactive multimedia applications, like sophisticated distance learning services. As a result, the system has to provide some sort of management architecture, which allows user management and other administrative tasks, for example billing. Furthermore, the server framework fulfills the following features:

- High scalability, availability, reliability, security and support of mobility aspects
- Good performance with regard to transfer rate, number of clients, bandwidth
- Integration of various applications (audio/video, text, graphics, interactive application programs, games...)

Although a prototypical implementation of the system has been developed, much needs to be done before the framework can be applied in a commercial environment. Further research should be done on the integration of other time-sensitive applications, for example interactive games, and performance aspects have to be evaluated.

A Services-Based Architectural Model for E-learning

Dimiter Bogdanov
Software Engineering Department
Institute of Computer & Communication Systems
Bulgaria
bogdanov@iccs.bas.bg

Abstract: A multi-model services-based approach for modeling the reach functionality of a learning process is presented. It allows the functionality to be split in different layers that are functionally orthogonal. The handling of activities over each layer is mapped to a suite of protocols. This way a not purely hierarchical decomposition of functionality is achieved and it is closer bound to distributive nature of learning environments. Explored generic Streaming Learning Architectural Model is appropriate to cope with dynamic tasks in learning as are the bi-directional interactions and messaging, collaborative learning, learning forums and presentations in real-time.

Introduction

The major e-learning initiatives (ADL 2001, IEEE 2001, IMS 2001) model the e-learning via a set of end-users requirements and try to map them onto existing digital technologies that are represented by Web paradigm mainly. They are concentrating on learning content delivering first and foremost. In fact, the education process is more complex and needs more than the Web paradigm - and HTTP protocol behind it - could offer. The complexity of e-learning is arising from requirements on dynamism and entity semantics handling. The Web, even with its extensions as DHTML and scripting models, is not capable to map all functionalities that may occur in a collaborating learners class - bi-directional interactivity, events handling, learner behavior tracing and steering, system state preserving, etc. The Web is also suffering on lack of mechanisms for entities semantic handling. In our understanding the Web is just one of possible handlers that acts in a client/server model. The investigated architectural model is assuming that other handlers in a client/server environment could be used also and other than client/server paradigms could be applied like P2P model for instance.

The services-based architectural model

The e-learning architectural model under consideration is not assumed to be Web-centric one, although the Web is one of the major handlers used for content delivering and rendering of information still. The presented architectural model is built up around two main ideas. The first one is that learning is modeled after a set of services representing some pieces of functionalities from a subject perspective. On the other hand, from an IT perspective, the services are small entities that could be transferred over the network and programmatically handled. The second e-learning model idea focuses on what framework is needed for services processing and handling. A protocol framework is proposed for services handling over the distributed learning environment. The protocol framework is a suite of protocols each of which is responsible for a primary class of services. The protocols are acting in layers as is shown in the illustrative layers decomposition scheme (Fig. 1).

The learning activities are time-framed as they are to be performed in a finite interval in general. Performing of the learning activities is usually related with transition through different states and an initial and end state of this process could be differentiated. In most cases the time for activities is not crucial and it is important to follow a preprogrammable sequence of steps. That is why we are viewing the learning activities as sequence-framed. The execution of a learning sequence is considered as a stream of interchanges that are behind the sequencing. The carrier of encoded expertise is called stream. The stream could be a peer-to-peer communication, a multicast or a broadcast. A stream as a logical production consists of: learning services, instructions and a set of supervising agents all organized as a scenario, which is to be performed within a session.
The logical structure of a stream is embedded in a stack of layers represented by XML technologies (XML 2000). The functionalities of these layers are illustrated in (Fig.1). The investigated elearning architectural model is consequently named Streaming Learning Architecture Model (SLAM).

Figure 1: Streaming Learning Architecture Model

The sequencing could be triggered and/or redirected on the base of an event model. The streaming layer protocol is responsible for monitoring of the sequencing of learning content. Further it is supposed that the stream is carrying not directly the learning objects but aggregated entities called services. This way the learning is presented by a set of services. All learning activities could be decomposed into sub-groups like services, sequencing, events, etc. and these sub-groups form functionally orthogonal layers. A protocol is responsible for each layer realization that technically could be implemented as part of other layer protocol. As basic protocol could be considered the stream protocol but it is also embedded in two other layers - session and scenario layers.

Conclusions

A multi-model services-based approach for modeling the reach functionality of a learning process is presented. It allows the functionality to be split in different layers that are functionally orthogonal. The handling of activities over each layer is mapped to a suite of protocols. This way a not purely hierarchical decomposition of functionality is achieved and it is closer bound to distributive nature of learning environments.

Explored generic SLAM model is appropriate to cope with dynamic tasks in learning as are the bi-directional interactions and messaging, collaborative learning, learning forums etc. The anticipated base for model implementations is widely accepted and agreed for standardization XML platform.

The presented reference elearning model has been used for development of a set of specifications (Bogdanov 2001) defining a unified methodology for designing of distributed learning environments. The specifications are described in an IEEE LTSC format.

E-Learning in College and Corporate Settings: The Present State and Beyond

Abstract:
Who is making the decisions about e-learning? What tools, resources, and courseware do college instructors and corporate trainers favor? And what are some common experiences and trends in e-learning? Based on two extensive studies in the college and corporate markets, this session will document the incentives, support structures, skills, tool preferences, and experiences of both college faculty and corporate trainers. In effect, the presenter will summarize two comprehensive survey reports, one on e-learning in corporate training and one on e-learning in higher education.

Introduction:
During the past few years, it seems that every technology-related newsletter, magazine, conference, and institute has expressed at least some an interest in e-learning. Despite the high interest, countless questions surround this new training delivery mechanism. Are course completion rates as well as costs higher or lower than in conventional classroom training? What types of tools and instructional techniques are most prominent on the Web? And what evaluation methods are valued and increasingly common here? In effect, just why are different firms and organizations interested in placing their training programs on the Web and how are they allocating resources to support it? And what about the emergence of the cyber university and online courses? What are college faculty experiences, preferences, and attitudes toward e-learning?

In attempting to answering some of these questions, the presenter has just completed two fairly comprehensive reports, “Online Training in an Online World,” and “Online Teaching in an Online World,” co-sponsored by CourseShare.com and Jones Knowledge, Inc. (see: http://www.publicationshare.com/ or http://www.jonesknowledge.com/). These free reports (as well as briefer summary reports) detail the e-learning attitudes and preferences of college faculty as well as corporate trainers, training managers, and other human resource personnel.

These reports have many goals, including:

- Assessing the e-learning resources and tools that college instructors trainers currently use as well as desire,
- Documenting reasons for sharing course materials and resources on the Web,
- Determining the types of online learning tools currently used as well as needed,
- Discerning some of the pedagogical practices and motivational techniques supported by e-learning,
- Revealing the support structures for online learners, instructors, trainers, and course designers, and
- Pointing to the present state of e-learning as well as future trends and directions.

Importantly, these report addresses emerging topics such as online learning communities, reusable learning objects, and freelance instruction. In addition, there are findings and recommendations concerning e-learning tool development, time, organizational support, content development and outsourcing, and evaluation and assessment.

Across the findings, it is apparent that the Web is flourishing as a teaching and training delivery mechanism. As one might expect, the most common forms of online training are computer applications,
technical skills, and job-related skills. In higher education, online training is more varied. In stride with recent reports on e-learning, respondent organizations tended to rely on blended or hybrid approaches wherein Web-based training supplemented and, hopefully, enhanced face-to-face instruction.

Despite the explosion of interest, the survey respondents noted significant organizational and cultural barriers to e-learning including perceptions of high cost and extensive instructor preparation time. In addition, there were technological problems related to bandwidth, firewalls, and limited technical support. Respondents also alluded to a need for more innovative e-learning tools that provide interactive feedback, multiple forms of collaboration, and enhanced learner evaluation and assessment. In terms of the latter, some firms are experimenting with alternative forms of evaluation that extend beyond the first two or three levels of the Kirkpatrick framework (i.e., reaction, learner achievement, and job performance). Nevertheless, when it comes to formal e-learning assessment, few instructors and institutions have made much progress.

Across the findings, there also appeared to be a need to train instructors and instructional designers in Web-based instructional approaches and opportunities. As this new learning format gains in reliability, acceptability, and interactivity, support structures are necessary for those building and refining their online courses, those administering and delivering them, and those taking them. In fact, innovative portals might provide expert guidance on purchasing decisions and vendor selection, content development, and the implementation of e-learning systems. And when high quality courses are developed, leased, or purchased, they need to be promoted by the university, company, or organization.

In the end, successful online training requires comprehensive support programs; if one aspect is nonfunctional (e.g., lack of student or employee access to e-learning), the new system will not succeed. Support might be live as well as online and intrinsic as well as extrinsic. The two reports will hopefully help sort out the choices and resolve some of the complexity. Specific information on these reports is provided below.

Report 1. "ONLINE TEACHING IN AN ONLINE WORLD"
CourseShare.com and JonesKnowledge announce the first of a series of joint survey research reports related to the use of the Internet in teaching and learning. This comprehensive report, "Online Teaching in an Online World," is available for free (see http://publicationshare.com/ or http://www.jonesknowledge.com/higher/index.php). The 75 page report addresses the use of the Internet by 222 college instructors, from both public and private institutions, who were early adopters of the Web. Instead of randomly surveying college instructors about their Web-based teaching needs and experiences, this research targeted those with some experience in using the Web as a teaching and learning resource, either in the World Lecture Hall or in MERLOT.org. Interesting findings are reported related to freelance instruction, student course attrition, and e-learning decision-making. Several key implications regarding instructor training, support, and resource exchange are also provided. In addition, there are recommendations concerning online learning policies, pedagogy, research, and courseware development.

Report 2. “ONLINE TRAINING IN AN ONLINE WORLD”
This January 2002 report, “Online Training in an Online World” is available for free at: http://publicationsshare.com/ or http://www.jonesknowledge.com/corporate/index.php. The 143 page document (as well as a briefer summary report) details the e-learning attitudes and preferences of 201 trainers, training managers, and other human resource personnel. The final report explores a number of e-
learning issues and future trends, such as the types of training offered online, the range of organizational commitment to e-learning, and the cultural and organizational factors limiting the adoption of e-learning. The report also addresses e-learning content development as well as outsourcing, instructional practices, motivation techniques and incentives, learner and instructor support mechanisms, and tool growth areas. Several key implications are noted related to the development of online trainer communities, reusable learning objects, e-learning partnerships, and freelance instruction. In addition, there are recommendations concerning tool and content development, pedagogical practices, organizational promotion and support policies, evaluation and assessment, and next steps in research related to e-learning.

Note: The Executive Summary of this report was published in March 2002 in USDLA (United States Distance Learning Association) Journal. http://www.usdla.org/html/journal/MAR02_Issue/article02.html
An object-based system for developing and delivering e-learning content

Louis M Botha
Academic Support Services
Potchefstroom University for CHE, South Africa
basimbi@puknet.puk.ac.za

Abstract: The Web as a medium for the delivery of learning content is totally different from printed text. Some of the major differences are in the way content is created, formatted and presented to learners. If traditional textbooks and study guides are simply converted to Web format using for example a word processor, we are misusing this new medium. In a Web-based learning environment content should be fragmented into smaller chunks. There are many reasons for this fragmentation: readability, manageability, relevancy, etc. The fragmentation must be part of the content writing process and cannot be fabricated afterwards. We believe the fragmentation, structuring and linking of Web-based content are very closely coupled to the content creation process itself. A LCMS was developed to address certain content authoring requirements.

Educational Issues

We are used to a sequential world: television and radio are all examples of pre-defined sequences of information. Although not constructed in a linear fashion, the result is a linear sequence of information blocks that cannot be re-arranged. The same is true for printed text. Physically a book starts at page one and is usually read in a linear fashion to the end. These sequences are fixed for all the readers. It is therefore “normal” to think that we should create and deliver E-learning content in the same linear fashion.

Information technology is making authors from all of us: it is quick and easy, and therefore I am an author. To make things even worse, authors and instructional designers are given traditional authoring tools like Word processors to create web-based content. Although tools like Dreamweaver and Frontpage are available, they are much too complex for most lectures. New software is required to enable structured and controlled content creation within a virtual learning environment by all team members (graphic designer, instructional designers, lectures, administrators). We strongly believe that Web based content should be developed in the same environment where it will be delivered. It should also be done by the lecturers themselves. If not, they should at least be able to update content. The authoring tools in the Varsite Learning Content Management System (LCMS) can address a lot of these issues through the implementation of learning objects in an object-based system.

Previous work and background

Until recently, faculty (authors) at the PU for CHE made use of a Word processor to create web-based study content. Authors were given a template consisting of the required headings and sub-headings. This template contained the structured levels of the study guide. The structuring is important and must be done before any writing commences. A conversion is then made from the linear document to a web document using a commercial product. The converter generates an HTML document for each heading level of the original document. It also generates a tree-view table of contents for easy navigation with expandable sections.

This process worked quite well, except for one problem, the authors never get to know the medium that they are actually writing for. Even though the instructional design is for the Web, authors still tend to write in a style that is for printed text. Further more, they could only see their results after each conversion made by Academic Support Services.

The Varsite LCMS

The Varsite system is a so-called Learning Content Management System (LCMS). It differs from the traditional LMS in that it also includes an integrated content authoring system directly linked to a central database. All learning content is treated as learning objects with properties or attributes. Custom properties can be added to the standard properties according to specific standards e.g. IMS.

The system was not only developed to address the educational needs mentioned in this paper. After a thorough evaluation of a few learning management systems in 1998, the university decided to build its own. The reasons are beyond the scope of this paper. But it is worth mentioning that critical requirements like enterprise level integration, integrated authoring and offline functionality was key factors in the decision.

The object-based design forms the basis of the complete system. Therefore all data, whether learning content, user
information, curricula information or management information, are stored as objects in the central data store.

**Content management and authoring**

Our requirements for web based authoring are stated below. All of these objectives were met by implementing the *Varsite* system. It must be kept in mind that we believe lectures must eventually be able to create their own Web-based content. This will mostly be used to enrich contact education on campus.

**Objective one: Authoring in the medium**

The main objective here is to enable authors to develop web-based content in the same medium in which it is delivered, but without the technical knowledge that is usually required to do this. This was achieved through the implementation of a full-text Web-based word processor. This enables full text formatting inside the Internet Explorer web browser. The content is saved directly to the object store on the *Varsite* server. Text from other Windows based applications can be copied and pasted into this editor. When a user is logged on as an author, an edit icon will appear next to all content.

**Objective two: Fragmented authoring**

The system enables the hierarchical creation of topics or pages to produce study guides. Each page is treated as an individual piece of content in the sense that it is individually seen and edited. There is no linear editable document. In a sense this enforces the basic design rules for the web for example manageable chunks, standalone content, single page topics etc. It also enables authors to focus on the specific topic without the distraction of other surrounding content, as would be the case with a traditional word processor. Authors see their content exactly as the learners would see it.

**Objective three: Tagging en describing content**

Since the object-based (and object orientated) model was implemented as a technical requirement for the whole system, the implementation of learning objects came natural and easy. Some basic object properties were implemented and these will later be extended to include some of the standards for example IMS. Each object is uniquely defined by a human readable name, in the same way as folder paths in the Windows environment. For example the object called RINL111:BOOKS:COMPUTER_SKILLS:UNIT3:INTRO is an introduction page of study unit 3 in the computer skills study guide in the RINL111 course.

**Objective four: Storing all information in a central database.**

Institutions cannot afford to have their intellectual property distributed as files on hard disks, network drives and web servers. A Central database is a must for backup, security, copyright issues, property rights, re-use, searching etc. This repository will eventually enable the creation of brand new modules from existing content.

**About learning objects**

Potentially, the implementation of learning objects has a lot of advantages for authors, learners and administrators. Some of these are already visible as indicated in the content design objectives. As time goes by and the need arises, we will implement it further. Future development will include (a) real reusability between lecturers, university departments and between universities, (b) adaptive learning paths for study guides and assessment and (c) custom study guides according the learner profiles.

**Results and feedback from authors**

In 2001 a complete Web-based course was developed over a period of about 6 months. Once the structure of the course content was designed, each of the four authors was able to create their own content simultaneously in the system. This shortened the development time drastically. Since the developed content was immediately visible on the Web, the project leader and quality control members could monitor the project continuously. The overall feedback from the authors was positive.

**References**

Abstract: This paper is a report on the findings of a two years study conducted on the undergraduate course “Teaching and Music Technology”. First, the components of the WebCT content developed for the first year of use are described. Then, the results of the assessment by the students of the usefulness of each of these components are presented. Findings indicate that many were not assessed as useful. The redesign of the whole components is explained and the second year WebCT components are described. Again, the results of the assessment by the students of the usefulness of each of the components are presented. The results allow us to provide more meaningful definitions of several design criteria for Web-based courses proposed in the literature.

Introduction

“WebCT (short for Web Course Tools) is an integrated set of tools for developing and delivering interactive course or course components over the Web” (Friesen, 2000, p.3). The lack of equipment available to the students forced the professor to use WebCT to deliver the course components of the undergraduate course MUS-19673 Teaching and Music Technology, instead of developing a fully interactive course. As the author was aware that the adding of a Web tool does not mean any enhancement of the course because, as mentioned by Heines (2000), “… the determination of what really works is so difficult”, she used what we will call several “content prescriptions” found in the literature (such as Dwyer and Baker, 2000; Friesen, 2000). She also integrated what was said, during the numerous sessions and workshops she followed, as being “obviously helpful even if not empirical evidence found”.

The First Year Study

There were 30 students using the first release of the course “MUS-19673 Teaching and Music Technology”. The following are criteria found in the literature. As can be seen, they refer to what Gagné (1977) calls a defined concept. The main problem is that their definitions are not given:

- The pictorial information is presented clearly.
- The courseware provides information that accurately represents the topic.
- The courseware screen layout is easy to understand.
- The courseware content is presented clearly.
- The text information is presented clearly.
- The graphical information is presented clearly.

Findings From the First Year Study

In accordance with the first criteria listed, and because the professor wanted to have icons nearest of the students interest, being the music, the icons used in the main window were “musical” ones. This design choice was assessed by the student as being a very important one. The different parts of the course notes, the
course plan, the description of the exercises to perform, etc., were put on the web. Students found it was not convenient because as they are often on the road to present concerts, they don't have any access to computer equipments. Students did not like the "book-like" table of contents presentation of what will be cover during each meeting with the group. They would have preferred a more "mnemonic" style. Students did not like at all the quiz options mostly because it did not correspond to anything they will have to use later in their career. They also found the email option integrated within WebCT not pertaining. They all wanted to keep their current email account and did not even check their mail inside WebCT. Students suggested to put several banks of examples and counterexamples that would complement, in a dynamic way, several aspects of the course content (For example, the principles of interface design or evaluation of a CAI tool in music).

The Second Year Study

There were 26 students using the second release of the course. As suggested, we added a large amount of examples, analogies, simulations, etc. We suppressed all the features students found not useful. We replaced the wordy table of contents by mnemonic one.

Findings From the Second Year Study

The adding of examples was assessed as being very useful. For example, in the course notebook, there is a section dedicated to the choice of colours for the interface of any computer product. Several recommended combinations are listed, i.e., the ones that does not cause damage to the retinal of the eyes. Visual examples of each combination mentioned in the notebook can be seen on WebCT. Another example is as follows: within the course notebook, the students learn that 8% of men and 4% of women have difficulties with viewing colours (colour blind) so, the learners is at risk to not see the very important information if it is coded with colours. Examples of screens that uses colour to present very important information are shown.

Conclusions

In this paper we have explained how a two years experimentation of our WebCT allows us to refine the definition of words such as "accurately", "clearly", and "easy" used in the literature when stating criteria of Web design. At first, when answering to the question "Does the courseware provide information that accurately represent the topic?", we were believing that linking the course notebook content to the table presenting what will be done during each unit was accurate. It was not find accurate by the students. It would rather be something that shows examples of what can be read in a printed course notebook, i.e., something dynamic. In the same way, we modified the meaning we first gave at the criteria "The text information is presented clearly". We found that students do not want to have wordy titles, but more mnemonic words that aim at helping them to make the link with the printed course notebook.

A Semi-Automatic Tool for the Indexation of Learning Objects

Yolaine Bourda, Bich-Liên Doan, Walid kekhia
Ecole Supéérieure d'Electricité (Supélec)
France

Abstract: The aim of this paper is to present a tool designed to help teachers (or other users) to describe their learning objects with IEEE Learning Object Metadata. This semi-automatic tool proposes default values based on the user profile for some descriptors and uses relations between documents to infer other descriptors.

Introduction

Metadata are necessary for retrieving learning resources and RDF is a good way to implement them, as we said in [3] and [4].

At the moment a learning object is created, it must be described by metadata (in the same way as a programmer comments the code that he writes, and if he does not do that immediately, he will never do it). Existing learning objects (with many possible file formats like pdf, word, power-point, java programs, latex, html and so on) have also to be described if we want to retrieve them. But an important problem is that, if we consider the IEEE LOM set of metadata, for example, we find about 80 descriptors. Some of them may be produced automatically for new learning objects (like "general.title") or for old ones (like "technical.format") but there are so few of them that the time spent to describe a learning object may be discouraging.

We propose a solution (a semi-automatic tool) based on both the profile of the person indexing resources and on the fact that resources are linked to each others by relations allowing to index a set of resources instead of a unique one.

Using the user profile

We consider that, when a user is indexing a document (a new or an old one), many descriptors, for that user, do not change from one document to another (like "lifecycle.contribute"). Furthermore, for a subset of that descriptors, some values remain more often identical for teachers coming from the same institution (like "rights, "educational.context" or "general.language"). So, for each user, we keep trace, in a database, of the values he or she prefers. These values can be edited either for a particular document or for the next ones. First, the user needs to be referenced and to obtain a login name and a password to access the tool. The values kept for an institution are the values preferred by the teachers of that institution. On the first access, the values of the institution (or default values for the first user of the institution) are proposed to the user, an initial but still editable choice.

Using relations between documents

It is really uncommon to create a unique new learning object and index it (or index a unique old one). In fact, an educational resource is made up of several connected learning objects. The idea is to take advantage of that fact and to use the meaning of the relations between resources to index them. When a teacher creates an educational resource, the learning objective is quite clear, the intended public is known and some descriptors are very close for all the composing objects. This is not always true may be, but this is a semi-automatic tool and it is always possible to change the values. Furthermore, the descriptor "general.AggregationLevel" can be deduced from the relations "IspartOf" from example, and the "LifeCycle.Version" from the relations "IsVersionOf".
For the indexation of a new learning object, the tool asks the user to enter the relation descriptor. If it is missing or meaningless, the tool retrieves the default values for the user's profile changing some descriptors like "title" or "date". A resource may be linked to more than one. So we propose the kinds of possible relations and for each kind we perform a specific task. We offer the user to enter the relations in a specific order ("IsVersionOf", "Replaces", "IsFormatOf", ...) and the tool retrieves the descriptors values from the first met. If we meet a "IsVersionOf" relation, the tool changes the version descriptor. If we meet a "IsPartOf" relation, the tool changes the granularity. If the learning object has several "References" relations, the tool performs the union of the keywords.

Therefore, our tool tries to guess the maximum of descriptors values. After that, all these values are proposed to the user allowing him to destroy or to update them or to entry new ones.

Furthermore, our tool enables the user to add some metadata to linked learning objects. If the learning object being actually indexed has a "IsPartOfRelation" with an existing indexed one, the tool adds a "HasPart" relation to it. For existing resources connected to indexed ones, the tool performs the same way.

For existing resources, if these are HTML files with meta tags implementing Dublin Core metadata, the tool takes them and add the default values from the user profile for the descriptors not included. But this case is very uncommon (in our experience, we have never found that kind of resources in our institution).

So, we propose the user to index a first learning object, with default values and we let him changing their contents. After that, we ask the user to enter the descriptors about relations. For each linked resource, the tool proposes to the user to index it using all the possible deductions due to the type of the relation.

A problem, not yet solved, is what to do when the deductions the tool made are not coherent (like two "HasPart" relations with two different granularities).

Our Goal

Actually, we are developing the described tool to help teachers to index their documents (with IEEE LOM metadata) based on the user profile and the use of relations.

In the first step, default values are suggested, assumed to be pertinent, for a large number of descriptors letting the user verifying their relevance and entry some of them (like "educational.difficulty" or "educational.TypicalLearningTime" with less meaning default values).

In the second step, more useful, the user is helped to index a set of connected documents with default and common values. Then, the user may edit and modify the values related to the whole set of documents or to a specific one.

As learning objects cost a lot of time to produce them, their re-usability must be improved. For such a goal, they have to be indexed by metadata. Our tool reduces indexing time and permits a better re-use and consequently a cut of the developing costs of learning objects.

Abstract: This paper discusses the notion of community as an outcome of working within an online environment. In particular the paper explores the concept of users' development of a sense of community as an outcome of working within an online environment designed to support the professional and personal development of its users. The paper discusses previous research which has explored the development of a sense of community and reports a study that sought to investigate the development of a sense of community among users of a community-oriented site supporting teachers' professional development.

Introduction

The social phenomenon of community can be put to good use in the support of learning through the development of learning communities. Although difficult to define it is evident that community is a central component of the lives of all individuals. People have always and will always form communities at one level or another as part of their existence. Indeed, community is such a central part of our lives that "if the sense of living in, belonging to, and having some commitment to, a particular community is threatened then the prospect of living rewarding lives is diminished" (Puddifoot, 1996, p. 327). The power of community to support learning rests with its centrality to our daily lives and an unexplained phenomenon where the sum of the parts of a community is in some way greater than the whole.

Virtual learning communities and their role in supporting learning

As we begin to explore the concept of community and its potential to support learning it is important to acknowledge that a positive sense of community can have many referents ranging from "family, fellow workers, friends, neighbours, religious and fraternal bodies" (Sarason, 1974, p. 153). It is equally important to acknowledge that community exists in both a geographic and relational sense and that the two are not mutually exclusive (eg. Worsley 1991). The online environment provides for the development of the relational community where members may never meet face to face. These communities have been dubbed virtual communities and have been identified as 'real' communities in a sociological sense (Surratt, 1998).

In the online learning environment the desired community is known as a virtual learning community. Maxwell (1998) recognizes the value of a learning community reporting on the positive influence learning communities have on both socialization and learning outcomes. Similarly Kellogg (1999) argues that learning communities promote more active and increased intellectual interaction and a sense of common purpose and Palloff and Pratt (1999) posit that the creation of a learning community supports knowledge acquisition. These communities are considered to be of such value in the support of learning that researchers believe the formation of virtual learning communities is central to the success of online learning (Hiltz, 1997; Palloff and Pratt, 1999).

Learning communities and learning

Learning communities support learning by promoting the benefits of collaborative learning environments. Socio-constructivist approaches to learning clearly provide evidence that when students work together their
cognitive development can be enhanced (e.g., Glassman, 2001). In collaborative learning environments students can become actively involved in the construction of new ideas and concepts and in this way student learning moves beyond the information presented to them (e.g., Bruner, 2001). Johnson (1991) asserts “that collaborative learning methods are more effective than traditional methods in promoting learning and achievement” and Benbunan-Fich (1997) concludes that “working in groups, instead of alone, significantly increases motivation, perception of skill development and solution satisfaction”. The benefits are not limited to the cognitive domain. Panitz (1997) identified 67 benefits spanning the academic, social and psychological domains. And Slavin (1990) posits that collaborative learning environments promote higher levels of motivation as well as social and attitudinal benefits concluding that the effect of collaborative learning on achievement is clearly positive.

In addition to the promotion of collaborative learning principles, learning communities promote a positive environment created by members who actively seek participation from others, valuing all members and sharing the results of their efforts (Moore & Brooks, 2001). This positive environment and members’ preparedness to work collaboratively are indicative of virtual learning communities and fundamental in the support of learning.

**Strategies that support community development**

Unfortunately little scientific research exists to guide the development of a virtual learning community although some strategies have been identified through anecdotal records (Palloff & Pratt, 1999). Combining these strategies with knowledge of community gleaned from the social sciences provides initial support in the development of virtual communities.

Establishing a welcoming personal environment is an important strategy in constructing the ‘human’ elements of community (Hiltz, 1998; Palloff & Pratt, 1999). And facilitating regular and meaningful communications where members can interact and share their ideas and concerns (Moore & Brooks, 2001), is central to the functioning of a community. An additional strategy is to provide an initiating reason which may be a disorientating dilemma, an issue, a concern, a contentious discussion or a particular community problem (Moore & Brooks, 2001). Further impetus can be gained by emphasising the benefits associated with becoming a community member. These benefits could include an increase in intellectual capital (Stewart, 1997), reciprocity or an increase in social capital (Putnam, 2000). Further support is found in the seven basic steps outlined by Palloff and Pratt (1999) (Table 1).

**Determinations of the development of a sense of community**

Prior to engaging in the measurement of community it is important to understand that community is a sense rather than a tangible entity and it is members’ sense of community (SOC) that should be identified and measured. McMillan and Chavis (1986) define SOC as a “feeling that members have a belonging, members matter to one another and to the group, and a shared faith that members’ needs will be met through their commitment to be together” (p. 9). McMillan and Chavis further developed a four-dimensional model of SOC arguing the presence of four discrete entities in members’ sense of community, membership; influence; integration and fulfillments of needs; and a shared emotional connection.

The model provides a mechanism for understanding SOC but not for measuring the experience. This can be achieved via the Sense of Community Index (Chavis, Hogge, McMillan & Wandersman, 1986) based on the McMillan and Chavis (1986) four dimensional model of SOC. A measurement tool that has been shown to adequately assess SOC having validity across contexts (Chipuer & Perry, 1999).
Learnscope Virtual Learning Community

The dearth of empirical information describing the essence of community development and our interest in exploring how communities can be developed and maintained in online settings prompted the inquiry we report here. As part of a Web site evaluation project, we undertook to explore the degree to which users of the site sensed themselves within a community of users.

The Learnscope Virtual Learning Community is a Web site within Australia that has been designed to assist in meeting the professional needs of people within the Australian Vocational Education and Training (VET) sector (Fig. 1.). The VLC is a dynamic and interactive Web-based support system that seeks to support the development of a critical mass of VET staff who are able to use flexible learning approaches to accelerate Australia’s transition to the information economy. The VLC is supported by, and works within the Australian Flexible Learning Framework and represents one of a number of activities undertaken in the Framework to achieve the goal of providing Creative, Capable People (Australian Flexible Framework, 2001).

Fig 1: The Learnscope Virtual Learning Community Home Page (www.learnscope.anta.gov.au)

The LearnScope Virtual Learning Community consists of 3 main elements: the Community Hub, supporting interaction and communication between the various members. Includes a login area, a personal space, discussion forums; Go Learn, an area providing access to a variety of resources to support members’ professional development; and a Resource Centre, access to information and content about flexible delivery.

Since an important aim of the Web site was to facilitate professional development, the form of community which the site sought to develop was based on learning and personal development. We organized an inquiry process that would provide some information on the capacity of the site to create a sense of community among the users and we also sought to explore factors that might influence the scope and extent of the community development. The purpose of this inquiry was to explore the development of users’ sense of community obtained from use of the site. Users of the VLC were asked to complete an online questionnaire which probed aspects of their use of the site. One component of the questionnaire asked users to respond to a series of questions that probed their perceptions about:

- Their sense of membership of the VCL community;
- The sense of influence they had within the community as a consequence of their involvement;
- Their sense of the extent to which the VLC facilitated integration and fulfilment of needs
- The users’ sense of a shared emotional connection with other users.

The series of questions was based on the questionnaire developed by Chavis, Hogge, McMillan and Wandersman, (1986), and included the items shown in Table 2 below. The online questionnaire was completed by 121 participants who considered themselves as more than casual users of the site.

The feedback provided strong support for the supposition that the site did provide users with the support and connection required to give individuals a sense of participation within a community. Users' responses for the scale exploring their sense of the extent to which the VLC facilitated integration and fulfillment of needs indicated a strongly positive response. The questions exploring users' sense of membership tended to return the least positive responses. It was evident that within the large user base that while many users were comfortable with the interactions and connection, the size of the user base precluded any personal relationships and the ensuing sense of membership which is usually associated with such connections.

The users seemed to gain a relatively strong sense of shared emotional connection from their experiences. The item with the lowest rating was that which sought to determine the value of the VLC to users. While the users appeared happy to participate in the community and felt that they were dealing with people with similar interests, there was a sense among many that the community was not overly important to them in the big picture.

Users reported quite positive responses to items that sought to establish their sense of influence within the community. The responses indicated that users generally felt well supported by others but it appeared that many felt that their contributions were not perhaps that significant in the overall community. Given the large numbers of users and the diverse nature of their backgrounds and previous experiences, the responses provided relatively strong evidence of the site giving users a sense of community among those participating.

Factors influencing sense of community

The inquiry sought to establish factors which appeared to influence the SOC experienced by users of the VLC.
a. **Level of expertise with ICT**: Users provided an indication of their perceived level of expertise with learning technologies using a scale ranging from 1 low through to 4, very high. An inspection of the means scores achieved by students reporting the different levels of expertise showed very consistent scores (Figure 1). It appeared that background knowledge of the subject matter on offer was not a factor overly influencing users' sense of community development. A one factor analysis of variance was used to test for differences among users' sense of community based on perceived levels of LT expertise (Figure 1). The results did not indicate any significant differences in sense of community against this factor ($F (3,99) = 0.388, ns$).

b. **Level of experience with ICT**: A second test was carried out to explore whether users' perceived levels of ICT experience was a factor influencing the development of a sense of community. Users were asked to report their levels of expertise with information and communications technologies (ICT). Their responses varied from score of 1, low levels to scores of 4, very high levels. Once again, the means scores achieved by students reporting the different levels of expertise were very consistent. A one factor analysis of variance was used to test for differences among users' sense of community based on perceived levels of LT expertise. The results did not indicate any significant differences in sense of community against this factor ($F (3,99) = 1.008, ns$).

c. **Level of access to ICT**: A third test was carried out to explore whether users' levels of access to ICT was a factor influencing development of a sense of community. Users were asked to report their levels of ICT access using responses of 1 (limited access) or 2 (access not limited). A one factor analysis of variance was used to test for differences among users' sense of community based on access to ICT. The results did not indicate any significant differences in sense of community against this factor ($F (1,101) = 1.192, ns$).

d. **Level of use of the VLC**: Another test was carried out to explore whether users' levels of use of the Community Hub was a factor influencing development of a sense of community. Users were asked to report their levels of use of the Community Hub using responses of 1 (limited use) through to 4 (regular use). A one factor analysis of variance was used to test for differences among users' sense of community based on use of the Community Hub (Figure 4). The results indicated a significant difference at the .05 level ($F (3,99) = 2.94, p <0.05$). This finding was in accord with expectations and supportive of the notion that the interaction was an important factor in building the sense of community within users.

e. **Level of use of the Resource Centre**: A further test was carried out to explore whether users' levels of use of the Resource Centre was a factor influencing development of a sense of community. Users were asked to report their levels of use of the Resource Centre using responses of 1 (limited use) through to 4 (regular use). A one factor analysis of variance was used to test for differences among users' sense of community based on usage of the Resource Centre. The results indicated a significant difference at the .05 level ($F (3,99) = 5.46, p <0.05$). This finding could be interpreted in much the same way as we interpreted the finding that use of the Hub was a contributing factor to the development of a sense of community. It might well be however, that this finding shows that users who made a high level of use of the Hub also made a high level of use of the Resource Centre. When the levels of usage of the Hub and resource Centre were compared, there was a significant correlation ($r^2=.33$).

These findings are quite interesting in light of the nature of learning communities supported by online environments. It is difficult to speculate too much with the results. They suggest that the development of a sense of community by users of the Learnscope VLC was not influenced by such features as their levels of experience and ICT access. The findings suggest that the sense of community is developed very much by use of the site and that all users appear capable of developing community membership through use of the site. We have taken this finding as evidence that the Learnscope sight is in fact returning in some way, the forms of outcomes that it was developed for.

**Summary and Conclusions**

The use of online facilities to support and sustain the development of communities of learners is becoming quite common among many educational groups. In this paper we have discussed the notion of a learning community and possible ways by which the development of communities might be determined. An exploration among users of the Learnscope Virtual Community, suggested that this site did in fact provide learners with a sense of community. A further exploration of factors that might have been likely to influence learners' sense of...
community revealed that aspects such as ICT expertise, levels of access and previous experience had no discernible impact on the development of SOC among learners. What was found to be important, and as might be expected, was the level of use of the site. Interestingly we were unable to demonstrate which sorts of activities had the greatest impact on the development of SOC and this arises as a possible line of inquiry for further work.

The findings from this paper appear to support the need for more research and inquiry into the development of community sense among users of online sites that aim to promote users personal development through such processes as interaction and communication with others. The data gathered in this inquiry provided evidence that the users of the Learnscope site did in fact establish senses of community of varying degrees and suggest the need for more work to more fully investigate what sorts of online activities hold the best prospects for community development.

Web-based Interactive Visualization
in an Information Retrieval Course

Peter Brusilovsky
School of Information Sciences
University of Pittsburgh
Pittsburgh PA 15260
peterb@mail.sis.pitt.edu

Abstract: Interactive visualization is a powerful educational tool. It has been used to enhance the teaching of various subjects from computer science to chemistry to engineering. Surprisingly enough, in computer science education, this powerful tool is used almost exclusively in programming and data structure courses. This paper suggests that visualization could be very helpful in teaching a larger variety of computer science courses and also presents several visualization tools that have been used in the context of an information retrieval course.

Introduction

Interactive visualization is a powerful educational tool. Visualization can provide a clear visual metaphor for understanding complicated concepts and uncovering the dynamics of important processes that are usually hidden from the student’s eye. Visualization has been used to enhance the teaching of various subjects ranging from chemistry (Yaron et al., 2001) to mechanics (Hampel, Keil-Slawik & Ferber, 1999) to physics (McKenna & Agogino, 1997). Computer science is one of the most active application areas for educational visualization research. In computer and information science (CIS) education, visualization is used almost exclusively in programming and data structure courses. We can name dozens of papers devoted to visualization of program execution on several levels from machine-level languages (Butler & Brockman, 2001) to high-level languages (Domingue & Mulholland, 1998; Haajanen et al., 1997; Tung, 1998) to algorithms and data structures (Brown & Najork, 1997). Our claim is that a number of other traditional CIS courses could benefit from this powerful technology.

This paper explores the opportunities for using interactive visualization in the context of an information retrieval course. Information retrieval has been in the program of many computer, information, and library science departments for more than 30 years. With the maturity of the World Wide Web, information retrieval became an important practical subject. Elements of information retrieval are now taught to students of many different specialties. We think, that information retrieval provides an interesting and important application area for exploring the power of interactive visualization. In the following sections we discuss the use of visualization in teaching information retrieval and present several visualization tools developed at the University of Pittsburgh.

Visualization for Information Retrieval

The core of a traditional information retrieval (IR) course is a set of models, algorithms and technologies for processing, storing and retrieving textual information. This core has been already explored by now and placed on a solid mathematical foundation. Traditional presentation of this core usually starts with several IR models (such as Boolean, vector, probabilistic and several variations of them) and then follows by explaining how the information is organized and retrieved in each of these models (Baeza-Yates & Ribeiro-Neto, 1999; Korfhage, 1997).

The process of retrieving the information in different models is one of the hardest topics in an IR course. Despite being formalized and well understood by the IR research community, it is still very hard for students to grasp. We have observed that even the Boolean information retrieval, the simplest of the models, is difficult for students. At the same time, traditional educational tools – research or commercial IR systems – offer little educational help. The process of retrieving the information has several steps, from getting the query in to matching the query to the documents to prioritizing the results. In an IR system all these steps are hidden
from a user – the only thing that a user can observe are the final results – a list of ordered documents. In that sense it is similar to a non-visualized execution of a computer program. A user can see input data and observe final results, but it offers no help in understanding how these results were computed.

Naturally, similar contexts encourage the use of similar remedies. So, the first thing we have decided to visualize is the process of retrieving the information in several known models. For the moment, we have developed and explored interactive visualization environments for several models – Boolean, fuzzy, vector, and extended Boolean (see (Baeza-Yates & Ribeiro-Neto, 1999; Korfhage, 1997) for the description of these classic models). Since space is limited and our environments are reasonably similar we present here in more details the one for exploring Boolean IR.

Interactive Visualization of Boolean Information Retrieval Model

The Boolean IR model is the oldest and the simplest of known IR models. In this model, a query is written as a set of elementary queries (usually keywords) connected by Boolean operators such as OR, AND, NOT. The mechanism of this model is set theoretical. Every query is associated with a set of matching documents. For an elementary query such as a keyword the set of matching documents is simply all documents indexed by this keyword. To obtain the set of matching documents for two queries connected by a Boolean operator one has simply to perform the corresponding set operation on their matching sets (i.e., set intersection for AND, complement for NOT, etc.). Thus in several steps, a matching set for any complex Boolean query can be found.

While it all sounds quite simple and clear, we have found that many of our students have problems understanding how the Boolean matching works. Our talks with students have indicated that one of the sources of their troubles is the failure to perceive Boolean operators as operations on sets of matching documents. Naturally, our students have good programming background and have been routinely using Boolean operators for writing conditional expression in their programs. Still, many of them have problems transferring their knowledge of these operators to the set context.

In developing an interactive visualization environment for the Boolean IR model we were trying to achieve two goals: to provide a helpful visual metaphor and to visualize the process of Boolean IR step by step. Figure 1 presents an interface of our environment. The core of this interface is a set of all documents visualized in a table (one document per row). Note that in our system, documents are textbooks since it is one of the most traditional kinds of documents.

![Figure 1: Boolean Model Environment. Visualization of matching for a simple Boolean OR query. Documents matching the first elementary query are highlighted.](image)
Figure 2: Visualization of matching for a simple Boolean OR query. Documents matching the second elementary query are highlighted.

Figure 3: Visualization of matching for a simple Boolean OR query. Documents matching the whole Boolean OR query are highlighted.
The goal of this representation is to help the student to understand the core principle of this model — every query is associated with a particular subset of all documents. Showing the set of all documents on the screen makes it easy to demonstrate different subsets of the whole set as sets of differently colored table rows. The goal of the whole environment is to help the student to understand (a) the process of matching an elementary query to the set of the documents and (b) how different set theoretic operations work in obtaining a new subset from contributing sets.

The student can explore Boolean matching by writing simple Boolean queries (two terms connected by one or two operators) and observing the matching process in these steps by clicking on each of the three buttons on the right panel.

The first button highlights the subset of documents matching the first elementary query (Figure 1), the second highlights the subset matching the second query (Figure 2) and the third, the results of the chosen set operation on the contributing sets (Figure 3). We choose to have three buttons to enable the student to explore the matching process several times forwards and backwards.

Beyond the component shown on Figures 1-3 the Boolean IR environment has several other components. In particular, to help the student transfer the understanding of Boolean IR from classic IR to the database context, we have provided a very similar exploration interface where elementary queries are constructed not from keywords as in classic IR but from restrictions on various fields of a database record (i.e., year = 2000 and publisher != kluwer). There is also a registration screen and an interface for a teacher to edit the collection of documents. The environment works on the Web and is implemented as a set of CGI scripts.

Other Learning Environments

As we have mentioned, the Boolean matching environment is just one of several interactive visualization environments that we have developed and explored. The environments for other models are reasonably similar. In all of them we have tried to center the visualization of the matching process on a visual representation of the whole set of documents in some form. The environments for other models are a bit more complicated (since the models themselves are more complicated) but they also provide the students with more opportunities for interactive exploration. For example, in the fuzzy matching model, an elementary query corresponds to a fuzzy subset. A fuzzy subset can not be shown by simply highlighting its documents – we need to show the “membership” of each document in a set. Thus an environment for fuzzy matching (Figure 4) has to provide extra fields for every document to show their memberships in all contributing queries (three rightmost columns on Figure 4) and provide the student an opportunity to re-sort the documents in the set by the value of each of these memberships.

Altogether our environments provide a very useful suite of tools for teaching information retrieval. We anticipate the use of these environments as both teaching and learning tools. First, we have found that these environments provide an excellent tool for a teacher to explain complex topics of IR models. Yes, it assumes that a teacher uses a computer and a projector in the classroom, but this is currently the standard context in most Computer and Information Science Departments. Still, computer projectors are most often used in classes to show the same static slides as in the age of overhead projectors and blackboards. By using the power of interactive visualization, our environments go well beyond traditional whiteboard and slides. At the same time, their use requires almost zero preparation time (just to plan which examples to show in order to cover the main set of ideas). The teacher can easily accommodate very different audiences by adjusting the number of examples to show, the speed, and the granularity of presentation. Even in a department with “computerless classes” the environments can serve as a powerful teaching tool to handle the questions and the problems of a troubled student in a one-to-one “office” context.

Using these environments as learning tools provides even better value. They let the students to switch from passive learning-by-reading to active and interactive exploratory learning. By exploring a number of different examples with an interactive visualization environment they should be able to achieve a better understanding of complex IR topics.

We have already performed an informal evaluation of several environments as teaching and learning tools in Summer 2001 semester and have got a very positive feedback from our students. Now we are planning an extensive formal evaluation during the Summer and Fall 2002 semesters.
Figure 4: Fuzzy Model Environment. Visualization of matching and ordering for a fuzzy AND query.
The documents are sorted according to the value of the membership function of the compound query.

Implementation Issues

It was a critical design decision for us to implement all environments as Web-based tools. Web interface ensures that our tools can be accessed anytime anywhere. It lets us forget about platform differences and avoid troublesome process of installation. This is very important in the context of college education where neither teachers nor students have full control over the computers used in the classrooms and labs. Besides, it offers an extra benefit in the context of Web-based and distance education enriching the learning experience of a remote student.

In fact, most of our environments were implemented with server-side CGI scripts. In the age of Java this choice is harder to advocate. Indeed, the first “pure Web” learning environments for computer science subjects were developed with CGI technology. Examples include both algorithm animation (Campbell et al., 1995; Ibrahim, 1994), and program visualization (Brusilovsky, Schwarz & Weber, 1996). However nowadays, Java is becoming a dominant technology for developing Web-based interactive learning environments.

We also use Java when it is necessary due to the highly graphical interface demands (for example, for set diagrams), however we were trying to avoid it when it is not necessary for several reasons. First, we have found that Java applets are not always working on the browsers installed on various campus computers. Second, one of our projects involves wireless access to learning tools using handheld computers (that have browsers with no Java support). Third, a CGI-based tool provides an easier platform for centralized collection of interaction logs, which provide the most useful source of data for our educational research. Fourth, we are working on adaptive interactive visualization (Brusilovsky, 1994) that requires the presence of a centralized server-side student model. Overall, we think that in the cases when advanced graphics or smooth visualization is not important the old CGI-based technology is simply better.

We should add that the suite of our tools for teaching information retrieval is available for teachers and students of any IR courses. The home page of this project is http://www2.sis.pitt.edu/~ir/Projects/. Currently, all tools are running on our servers and could be used by anyone who is interested to teach or learn information retrieval and have access to the Internet. We are also working on packaging these tools as public domain software to be installed wherever someone wants to use it.
Currently we are working on developing several other environments to support teaching and learning of IR. In these environments we were exploring different visualization metaphors (such as set diagrams) to demonstrate matching process as well as the use of interactive visualization to support other traditionally hard topics of an information retrieval course.

Abstract: Assuming that learning within project groups requires both cognitive skills and a cooperative orientation of the students involved it is hypothesized that groups describing themselves as 'functional' consist of both more 'higher achieving' students and more 'cooperatively oriented' students as compared to groups describing themselves as 'dysfunctional'. Based on questionnaire-responses, 14 groups of about 10 students each could be categorized as either 'very functional', 'functional' and 'dysfunctional'. As hypothesized, moving from the 'dysfunctional' over the 'functional' to the 'very functional' category, group members' academic achievement increases. Opposite to expectations however, moving from the 'dysfunctional' over the 'functional' to the 'very functional' category, group member's cooperative orientation decreases.

Introduction

Small-group projects are often promoted as potentially powerful educational vehicles (e.g. Slavin, 1996). Interacting with peers might provide ample opportunity for the learner to engage in activities that facilitate long-lasting, firmly rooted understanding. Examples of such learner activities are “putting material into one’s own words”, “explaining own opinions and questioning those of others”, “revealing misconceptions that show up during group-discussions”, “clearing up confusion” and “summarizing or recapitulating ideas”.

In order to accomplish these activities learners should possess the necessary cognitive skills and maturity to do so. Next to cognitive abilities however, one might hypothesize that peer learning draws upon the learners' interpersonal skills to sustain and maintain a cooperative working relationship within the group. Learners should possess the competency to deliver feedback in a non-threatening and supportive way, asking for and actually taking into account suggestions of other group members and attaching importance to collective group-successes rather than being bent on personal victory.

Hypothesis

It was hypothesized that groups describing themselves as ‘functional’ consist of students with both a better ‘academic achievement’ and a more distinct ‘cooperative orientation’ as compared to students that belong to ‘dysfunctional’ groups.
Method

Subjects were 139 sociology freshmen. One (small) part of the study program required them to work on a group project covering the full academic year. There were 14 project groups of about 10 students each.

Questionnaire Research

During the final collective session (at the end of the academic year) students were asked to fill in a questionnaire. The questionnaire consists of two parts. One part comprised 10 existing scales measuring different aspects of the quality of group functioning (Bond and Shiu, 1997; Bradshaw and Stasson, 1998; Freeman, 1996; Kramer et al., 1997; Watson et al., 1991; Gaertner and Schopler, 1998; Wheeless et al., 1982). A second part measures students' 'cooperative orientation' on the basis of Van Lange's (1997a) 'social value questionnaire'. Both parts of the questionnaire were contra-balanced.

Part A: Quality of Group Functioning

For every group 10 scores (one for each scale) were calculated by averaging its members scores on that scale. On the resulting matrix (14 groups by 10 scale-scores) a cluster analysis was performed. Three clusters of groups appeared and were labeled 'very functional' (4 groups); 'functional' (9 groups) and 'dysfunctional' (one group). Members of 'very functional' groups (upper line in figure 1) perceived their group as a coherent and solidary entity, said they performed more efficient than if there were no groups, and believed their interactions resulted in decisions of good quality. Group-work was not perceived as a waste of time and one was satisfied with both the final result of the group work and the way group members interacted with each other. Although all members contributed evenly, some members were more dominant than others. Group scores on all scales were about one standard deviation lower for the 'functional' cluster and about two standard deviations lower for the remaining 'dysfunctional' group (lower line in figure 1).

![Figure 1](image-url)

Figure 1 Perceived quality of group functioning for 'very functional groups', 'functional groups' and one 'dysfunctional group'.
Part B: Social Value orientation

Van Lange’s measurement of social value orientation (Van Lange et al., 1997) consists of nine ‘decomposed games’. On every ‘game’ the subject can opt for either a ‘cooperative’ an ‘individualistic’ and a ‘competitive’ alternative. The number of ‘cooperative’ choices was used as an index of a subject’s cooperative orientation. The mean score was 6.19 (with a standard deviation of 3.4).

Academic achievement

Students’ global exam result (minimum = 0; maximum = 100) was taken as an index of ‘academic achievement’. The mean score was 57.1 (with a standard deviation of 8.95).

Quality of group functioning according to the project-groups’ instructors

Additionally, the two instructors who coached the project groups during the academic year were asked (together) to categorize the 14 project groups according to their ‘functionality’. Although instructors judged it a difficult task, their (collectively reached) solution matches quite well with the categorization based on students’ self-reportings. Instructors classified three out of the four groups in the ‘very functional’ cluster as ‘relative superior’. The one group classified as ‘dysfunctional’ was also the only group identified by instructors as posing ‘severe problems’.

Results

A MANOVA with both subjects’ ‘cooperative orientation’ and ‘academic achievement’ as the dependent variables, and ‘group functioning’ as the independent variable (containing three levels: ‘very functional’, ‘functional’ and ‘dysfunctional’) reveals a multivariate effect of ‘group functioning’ ($\lambda = .90$, $F(4,270) = 3.8$, $p = .005$). The between-subject test reveals that the multivariate effect is accounted for by both a univariate effect for ‘academic achievement’ ($F(2,136) = 416$, $p = .02$) and ‘cooperative orientation’ ($F(2,136) = 3.15$, $p = .05$). Students global exam results in the ‘dysfunctional’, ‘functional’ and ‘very functional’ groups were 54.8, 55.7 and 60.1 respectively. Students’ cooperative orientation decreased moving from the ‘dysfunctional’ over the ‘functional’ to the ‘very functional’ groups. Means were 8.7, 6.25 and 5.6 respectively. Planned comparisons indicate that ‘very functional groups’ consist of students obtaining better academic results as compared to ‘functional’ and ‘dysfunctional’ groups combined [$F(1,136)=5.96$; $p<.02$]. Additionally, students in ‘very functional groups’ are significantly less cooperatively oriented as compared to students in ‘functional’ and ‘dysfunctional’ groups combined [$F(1,136)=5.78$; $p<.021$]. The dysfunctional group on the other hand distinguishes itself from ‘functional’ and ‘very functional’ groups combined only by its members outspoken cooperative orientation [$F(1,136)=5.56$; $p<.02$].

Discussion

A first result of the research reported refers to the correspondence between students’ self-reportings on the one hand and the instructors’ opinion about the quality of group functioning on the other hand. According to the instructors it is but until the end of the academic year they obtain a rough picture about the way the different project-groups are functioning. Instructors said they nearly always remain uninformed about how student-groups are functioning during the initial stages of the project. Even when explicitly asked for, students often remain reluctant to report problems within their group, thereby preventing instructors to timely intervene. Having demonstrated however that dysfunctional groups can be detected using
questionnaires measuring different aspects of group functioning, a hopeful perspective is offered. Currently we are investigating if and to what extent group (dys)functioning can be mapped at the very early stages of group work.

A second result refers to the generalization (and the qualifying antecedents) of the benefits of project-based peer learning as put forward in educational research (e.g. Slavin, 1996). On the one hand, it seems that relatively large groups of learners are not necessarily dysfunctional, at least on condition they are composed of 'high achieving' and (relatively) 'noncooperatively oriented' students. On the other hand—and in strong contrast with our hypothesis—large groups that merely consist of extreme cooperatively oriented students perhaps run the risk to become dysfunctional. Asking students in the dysfunctional group to try and give a reason for the severe problems encountered, they indeed refer to explanations that can be linked up with a 'cooperative' or 'pro-social oriented' social orientation. For example, one subject described “the extreme frustration that resulted from writing, re-writing and writing again texts in order to take into account all group members' opinions ... and how everybody seemed to hesitate cutting knots for the same reason.” Additionally, knowledge of both learners' social orientations and their level of academic achievement, might direct both anticipatory and supportive actions of instructors coaching learners working together in (large) project groups.

Finally, from the point of view of social psychologist, the reported findings might question the unconditional generalization of the benefits of a pro-social orientation. Social psychologists have stressed the benefits of a cooperative social orientation in a very broad range of social settings (e.g. Van Lange et al., 1997b; Van Vugt et al. 1997). Without putting too heavy a weight on our findings (based on a limited sample it surely needs to be replicated) we however will suggest to further investigate the boundary conditions of the presumed benefits of a cooperative social orientation. Perhaps in the context of project groups, the absence of at least one non-cooperative group member (or someone that can fulfill the role of a leader?) is detrimental for the functioning of that group.

Interacting with Interactive Papers: A Situated Evaluation of a Computer-Supported Collaboration Tool

James G. Buell
Department of Educational Psychology
University of Illinois at Urbana-Champaign
United States
jbuell@uiuc.edu

Abstract: This study, currently in progress, examines how several groups of users have made use of our Interactive Paper Project (IPP) online resource (Buell & Levin, 1999; McCollum, 1999) in varied academic settings. Situated evaluations (Bruce & Peyton, 1993) involve analysis of three essential elements: the idealization of the innovation, the settings in which it appears, and the realizations within each setting. The study explores IPP use in five mini-cases, involving cross-classroom, conference and journal-editing implementations.

Introduction

The Interactive Paper Project resource (Buell & Levin, 1999; McCollum, 1999) is a web-enabled database that permits authors of papers to upload them to the web and allows readers to submit written comments at specific points in the body of the paper. These comments are immediately available for viewing as part of the paper itself. A two-level commentary structure allows for both comments linked to various segments of the paper, and responses to those comments. Figure 1 shows part of an IPP text, with comments and responses interspersed.

For example, students can revise the original procedures to produce more versatile Gossip programs. They can break apart the predication into transitive verbs with objects, or expand the range of possible subjects. They can add conditional actions to the procedures, for instance, that only certain people can do particular actions. As they construct their Gossip programs, they are forced to confront fundamental questions about language, such as: "What is the relationship between syntax and semantics?" "What is a word?" or "What makes a sentence interesting?" While the program has no means for answering such questions, it provides an environment in which students can seek answers themselves. It allows them to see the consequences of their own hypotheses about language.

Figure 1: Portion of an Interactive Paper, with a comment and a response displayed 'inline.'

The IPP is one of a variety of types of online resources allowing readers to add to or comment on an internet-accessible document. Others include usenet newsgroups, bulletin boards such as WebBoard (www.webboard.com), and weblogs, or "blogs" (www.blogger.com). The IPP structure places more emphasis on the original document than these other alternatives; different "views" allow the reader to view only the original text, to view the text with comments rendered "inline" (interspersed with the original text), or to view the comments as "linked" via a pulldown menu.

Interactive Papers were initially developed as an online version of academic "in-progress papers," draft documents passed from one colleague to another for comments and advice. While this has been one
major use to which the IPP has been put, a review of the documents created by IPP users over the past two years shows many more uses as well.

The Study

Our study examines the IPP from the viewpoint of Situated Evaluation (Bruce & Peyton, 1993), an analytical framework devised to evaluate "innovations in use" across different settings. Situated evaluations involve analysis of three essential elements: the idealization of the innovation, the settings in which it appears, and the realizations within each setting.

In the case of the IPP, an innovation originally idealized as an online white-paper delivery system has been used not only for that purpose, but also as a formal journal-editing mechanism, an avenue for informal communications between individual students and professors, an adjunct to a national conference, and a launching platform for segmented streaming video files. It has served audiences ranging from individuals sharing an office or classroom, to distance education students in the same course, to academic professionals on different campuses around the country. In several instances, developers have modified the basic IPP mechanism to better serve those interests and audiences; some modifications have afterward been applied to the basic IPP, while others have not.

Several mini-cases make up our situated evaluation of the IPP. One involves a single paper that has garnered more than 300 comments, mostly from students in classes taught by one of that paper's co-authors. A second case involves thirteen different papers presented at a national conference in Fall, 2000; these papers were made available in IPP format to conference attendees beforehand, and readers entered several hundred comments and responses. A third case looks at how the IPP has been adapted to serve as the primary means by which an online journal prepares articles for publication; article drafts are made available to reviewers for their comments in a two-phase process which initially keeps comments private, then makes them available to article authors and fellow reviewers. A fourth case examines how members of a cross-institutional research group are making use of the IPP as one of several mechanisms for promoting multi-site collaboration. A fifth case describes how the IPP structure has been modified to construct "interactive multimedia papers," by adding features for selecting and segmenting streamed video files so that these can be viewed and commented upon.

Implications

Our ongoing situated evaluation of the IPP is helping us understand better how the tool is being defined in use, and guiding us toward further revisions and improvements.

Abstract:

An instructional application consists of a set of resources and activities that implement interacting, interrelated and structured experiences oriented towards achieving specific educational objectives. Computer-based instructional applications have to be faced as any other development activity following a well defined process. With this purpose some design methods for computer-based instructional applications have been proposed. However most of them are focused on "on-line" courseware structures which are quite rigid as far as they have serious shortcomings to deal with courses structured in multiple ways. Moreover, these methods usually lack a specific mechanism to model instructional concepts and strategies. This work proposes a design framework to develop multi-structured instructional applications combining a didactic model with a software engineering approach to deal with educational and technical requirements. The underlying model extends knowledge structures, such as those involved in the Merrill's Transaction Instruction Theory, adding them didactic information. It also considers the functional aspects of these structures. An XML-based notation is proposed to represent such structures and their management.

1. Introduction

An instructional application can be defined as a set of resources and activities which implement interacting, interrelated, structured experiences that are designed to achieve specific educational objectives. Instructional applications are usually structured by means of static patterns which are based on a sequence of book-like electronic pages. They are designed using courseware methodologies that focus on presentation and navigation issues but lack a didactic basis. The resultant products are mostly "pretty-printing" on-line courses but didactic aspects are hardly considered. The current work proposes a design framework which is independent from computer-based delivery technologies and it allows the representation of multiple didactic structures from an instructional point of view. Such a framework requires a model to deal, on one hand, with instructional design topics and, on the other hand, with the design of computer-based applications.

Instructional design can be defined as the discipline that connects descriptive theories with instructional practice. Among the different instructional theories proposed in the literature, we will assume the Instructional Transaction Theory (Merrill 1996) since it makes possible to figure out the relationships between educational and technical components. Merrill's mental models consist of two major components: knowledge structures (schema) and processes for using this knowledge (mental operations). The Merrill's hypothesis states that adequate instruction would require multiple types of knowledge structures to be identified and made explicit to the learner. Thus, the Instructional Transaction theory provides a powerful tool to structure the knowledge about a given topic and to define the procedures for accessing it. In the framework proposed in this paper, Merrill's model is extended to add didactic information to knowledge objects and structures. A Didactic model is built using the previous entities as the basis and assigning them attributes whose values suggest how they can be used or even adapted in a specific learning or teaching scenario.

On the other hand, the proposed framework deals with the design of educational computer-based applications. Most of the existing methodologies are addressed to author courseware using formats such as HTML documents. They seem adequate for presenting and accessing information in a open environment like the Web but lack a data structuring capability. Another option is using proprietary multimedia authoring tools like Authorware™ or
Tooolbook™ that provide a more powerful data model but they bound the reuse and exchange of content module (Wiest, 2001). In this sense, an important effort has been made to organize and to manage educational data using metadata (Duval 2001). However, standard metadata proposals mainly aim at the reuse and exchange of learning material and they are not directly involved in the context of instructional application design. In the current work, notational systems based on metadata are used to represent instructional and didactic entities. The proposal consists of defining an XML-based notation which specifies the Merrill's Instructional Transaction Theory entities and their extension introduced in our Didactic model. Such notation will allow an instructor to define his own didactic structures which can be built from a common repository of instructional objects.

The remainder of the paper is organized as follows. Second section revises some related works. Third section introduces the design framework proposed in the current work. Such framework is based on a didactic model whose structural components are presented in fourth section. Fifth section complements this model with its functional view. An application example is described in section 6. Finally, section 7 presents some remarking conclusions.

2. Related work

There are several technology-based educational initiatives that propose a separation between didactic aspects and content related issues. In this context, the Multibook project (Steinacker et al. 1999) considers two domain spaces: the Concept Space and the Media Brick Space. The first one contains a network of knowledge topics which are connected via semantic relations. The second one contains information units of various multimedia formats. Media Brick elements are linked to the Concept entities and instructional mechanisms such as "example", "deepen" or "explain" are setup between these elements. A similar approach is proposed in LMML (Süß et al 2000) which differentiates Pedagogical and Instructional properties from the Module and Content objects. However, only strategy attributes with possible constant values "beh" (behaviouristic) or "con" (constructivistic) can be specified. Other proposals such as the Targeteam project (Flege 2000) or the Palo language (Rodriguez et al. 1999) are also constrained to relations or mechanisms such as motivation, illustration, exercise or explanation without an additional didactic value.

In metadata contexts, there are Educational Modeling Languages (EML) which allow the specification of many kinds of educational data. These data can be implemented using notations which take advantage of standard proposals on one hand, or particular and specific proposals on the other hand. The first option is used in the Multibook project to define the Media Brick elements from IEEE Learning Objects or the Chameleon project and its TeachML (Wehner 2001) notation that is based on IMS standards. These standard formats are useful for exchanging them in different learning contexts but their didactic attributes are very restrictive. In the second category, there are formats such as LMML that defines instructional ContentObjects which contain media units such as tables, lists, images or text. The problem is that these units are strongly coupled with instructional objects and it prevents to assign them with different media objects. Similar problems are found on other EML proposals such as Targeteam contents, EML learning objects (Koper 2001) or Palo elements.

3. Design of Instructional Applications

Figure 1 shows the global architecture in the proposed instructional application design framework. The upper level deals with Instructional Design Theory which manages entities such as "knowledge objects", "knowledge structures" and "transaction shells". According to Merrill, a knowledge object is defined as "a precise way to describe the content to be taught". Knowledge objects can be combined into knowledge structures. Knowledge structures are external representations of knowledge that are parallel with mental models that in turn are internal (cognitive) representations of models. Transaction shells consist of rules for selecting and sequencing knowledge objects. The entities defined in the Merrill's model are the basis for the next level (Instructional Design Modeling). This central level is characterized by a Didactic Model whose components extend the previous entities with didactic information. They are divided in two categories that represent the structural and functional model, respectively. Structural model is composed by instructional objects, derived from knowledge objects, and didactic structures which extend knowledge structures. Functional model is based on instructional tasks and learning scenarios. An EML notation is being designed to specify both structural and functional components. Next section will describe them in depth. The lower two levels deal with the computational implementation of instructional applications. The first one is based on a hypermedia model to represent the instructional entities and their relationships in an formal and abstract notation (Buendia et al 2001). The second level is related to the technology involved in the delivery of instructional applications using an e-learning environment.
4. Structural model

This section focuses on the structural components of the Didactic Model proposed in this paper. The simplest element of the current model is the Instructional Object (IO) which is used to manage Merrill's knowledge objects from a learning point of view. Instructional Transaction Theory describes knowledge in terms of three types of knowledge objects: entities, activities and processes. When an entity, activity or process is addressed in a learning context, there are multiple aspects that differ depending on the learning conditions around the knowledge object. The main goal of IO elements is to represent such aspects. If the learning target is an entity, IOs such as definitions, statements or examples can be used to describe it. Activity knowledge items can be characterized using IOs such as exercises, questions, analogies, hints and so on, and finally, processes are also qualified with simulations, feedback elements, or animations.

IOs are not only isolated information units such as definitions or exercises but they are also concerned with the way these units are used in a learning context. For instance, an entity definition is assigned with a difficulty level, a statement declares a property value assigning it a relevance index and an example displays the entity with a specific portrayal (text, audio, image, and so on). Therefore, IOs must consider the multiple possibilities for a knowledge object to be learned in order to deal with different learning styles and needs.

The model presented in this paper provides a flexible framework to incorporate multiple kinds of didactic information which can be added to IOs. The instructor has to decide the different difficulty or abstraction levels assigned to each object, its relevance in a certain learning context or the portrayal that requires a given user profile. This design process is highly related to the features of a subject domain and it becomes a manual and laborious process. Tools as metadata notations have been used to support this process.

In this work, there is a simple XML notation proposal and the definition of IOs is adapted according to the subject domain. This means that they can be defined on top of other entities such as Merrill's knowledge objects or IEEE learning objects, extending them with didactic elements as those referred in Figure 2. In this example, a Description IO is used to teach the "magnetic disk structure" (knowledge object). The "ObjectDescription" shows that an image representation has been selected in the current teaching context. Didactic parameters as the portrayal configuration or the abstraction type indicate how this image is displayed and the level of abstraction it represents. EML notations usually also include information about the organization of the educational contents in different structures. In some cases like the Multibook project this information is mixed with the own instructional objects. In our model, there is a strong separation between both types of information.

Instructional objects are organized using Didactic Structures (DS) which can be managed as independent entities. These entities are addressed to capture the didactic relationships between those objects. There are two kinds of didactic relationships in the current model: explicit and implicit. Explicit relationships link IOs using a specific action, for instance, “an example illustrates a concept definition” or “a question evaluates an explanation”. Implicit relationships are derived from the way knowledge items are organized.
In this case, we are interested in knowledge structures coming from the Instructional Transaction Theory which are used in the current work to model DSs. Merrill mentions different types of knowledge structures such as lists, taxonomies, dependencies, algorithms and causal nets. A DS can be built on top of one or more knowledge structures. For instance, the description of a magnetic disk in a computer system can be based on identifying its components and assigning them a portrayal configuration. It can also include an algorithm representation to show the access to a specific component (e.g. a cylinder). The DS connections with other model entities are represented on Figure 3. It shows a simplified UML diagram which specifies that DSs are entities aggregated from instructional objects (IO) and knowledge structures (KS). Both IO and KS entities are based on knowledge objects (KO) which are composed by elements such as Identif, Portrayal and Properties. DS entities also extend the basic information coming from IO and KS, using didactic attributes such as the portrayal selection.

The current work is closer to the IMSDL proposal (Silverhorn & Gaede 1999) which defines instructional strategies, responsible for structuring the information units to be learned but independent from the subject domain. However, these structures are addressed mainly for courseware. Nevertheless, we do not know any proposal focused on generating structure templates which can be applied in specific didactic contexts in a reusable and modular way. We are developing XML Schemas to represent a wide range of didactic structures from basic knowledge structures.

5. Functional model

The functional model describes the entities that allow a user (student or instructor) to interact with DSs. DS entities are the nexus with the other structural elements. Figure 4 shows a simplified UML diagram that represents the main functional entities and their relationships with the remainder entities. These entities are learning scenarios and instructional tasks, respectively.

Learning scenarios (LS) are defined as the set of terms and conditions that characterize the user learning. Each individual user or group of them is assigned with one or more LSs. Instructors have to configure the LS entities, assigning features such as learning modes, timing schedules, instructional methods and learning goals. Each LS aggregates one or more Instructional Tasks (IT). They are defined as the operations a user has to perform to achieve a specific learning goal. IT entities model the functions associated to the didactic structure interface. They can access to one or more didactic structures and a certain DS can be attached to multiple ITs.
ITs are related to the Merrill's concept of "transaction shell" which consists of rules for selecting and sequencing knowledge objects. In the current model, IT entities do not access directly to IOs which are encapsulated into the didactic structures. This feature eases the design process because the instructor deals with IOs in a more abstract way. For instance, in a dependency DS, the IO components are all considered as chain elements without differentiating them. An IT like Explain specifies the navigational operations through the branches of the Dependency structure. A navigational operation can consist in the selection of a given branch and it could depend on learning modes such as "learning by examples", "by doing" or by "exploration and experimentation". In the first case, the Explain task is based on revising Example IOs while the other cases involve the working with Activity IOs. One of the main instructor responsibilities is to define the ITs attached to each DS. This definition is also a manual and laborious task and an EML notation is being developed to assist the instructor in this process.

6. Application example.

In this section, an example is used to show the application of the proposed Didactic model. The example consists of a Didactic Guide called "Learning XML basics" which is based on a Dependency structure. Figure 5 shows a diagram of top-down dependency. The root node represents the main learning goal described as "Learning XML". The descendent node has assigned a Definition IO which intends to answer the "What is XML" question. The didactic relationship between the Goal and Definition IOs is an IsBasedOn relationship type and it means that the knowledge about the XML notion (current node) is required to meet the goal defined in the previous node. From the current node, there are several branches which represent extensions (IsExtendedBy relationships) of the current definition node. These branches store requirements in order to understand the previous node and each one has assigned a specific competency (difficulty) level. According to this assignment, a different IT can be attached to each branch. These competency levels are based on the learning modes cited previously. Learning by examples can involve identifying instances of a concept, e.g. an XML document (left branch) or a DTD document (central branch). Moreover, each XML document example can be assigned with a certain difficulty level which is used as parameter by the IT. It causes that the structure branches can be navigated-accessed in different ways. A Predict IT can check a specific process, e.g. the validation of an input XML document using a DTD syntax. This validation process is based on an Activity IO which is related to a previous Example object by means of an IsCheckedBy didactic relationship. In a higher level learning mode, the Predict task could include additional activities such as the DTD configuration.

7. Conclusions

A design framework has been proposed for developing instructional applications beyond the rigid courseware structures that underlie the typical Web-based courses. The proposed framework is based on a didactic model which provides a gateway between instructional theories and concepts, and hypermedia and Web application engineering. This model considers two issues: a structural view based on instructional objects and didactic structures, and a functional view that manages the previous entities using instructional tasks and learning scenarios. The didactic model is supported by an XML-based notation which eases its translation to computing environments.
This notation has been applied to represent taxonomy-like didactic structures. It provides the possibility to organize available educational resources in a way closer to the instructor teaching requirements. We have also planned to extend the XML-based specification to other didactic structures based on dependencies and algorithms. Further works include their usage in specific learning contexts such as Electric and Information Engineering areas. We are also developing a tool to allow the access to these structures in a Web-based environment.

The Construction Kit Metaphor for a Software Engineering Design of an E-Learning System

Michael Bungenstock, Andreas Baudry, Bärbel Mertsching
University of Hamburg, Dept. of Informatics, IMA Lab

Abstract: In this paper we propose a construction kit approach that could be used as an abstract model to implement modular defined e-learning systems. The metaphor construction kit results from the math-kit project, that provides students and lecturers with multimedia support for central topics in undergraduate mathematics. The lecturers can combine different learning units into individual courses as easily as bricks of a construction kit can be used to build a model. Thus, a learning unit which is developed by one author could be used by a number of other authors as well. Furthermore, learning objects must be defined independent of style and format, because the definition of design and style makes it impossible to integrate them into different courses. Therefore, we are using XML as the description language to define learning content in a structural manner. Our modular concept is based on the Sharable Content Object Reference Model (SCORM).

Introduction

When teaching mathematics to undergraduates and non-mathematical students, most lecturers agree that the use of computers in education is very helpful. Despite this, most of them don’t use computers in their standard lectures. The reason for this is that they lack the necessary technical knowledge to develop and integrate computer based learning units to their lectures. Hence, we are developing a multimedia construction kit, called “math-kit”, that supports lecturers and students with mathematical and technical content (Unger et al. 2002). Math-Kit is a joint project, which is being developed at the German universities of Hamburg, Bayreuth, Hagen and Paderborn. The developed system provides a simple mechanism to find and combine different learning objects to compose them to learning units and courses. These learning units are able to be used by lecturers for presentation as well as by students for exploration.

In a joint project the creation of uniform learning content is very difficult to achieve. Often different developers produce learning objects which are based on varying description languages such as HTML or PDF. Integrating learning objects into existing courses requires a lot of revision work to achieve consistency of appearance and content. To find an optimal solution, several learning platforms and authoring tools were evaluated but none of these met our requirements.

The Construction Kit

Nowadays, object oriented software engineering is a popular programming paradigm and provides objects as units of modeling. Regrettably, this level of modeling is insufficient for the development of complex software systems with human interaction. To bridge the gap between object and technical models, we use the metaphor concept in our project. A metaphor is a linguistical term which uses a figurative meaning in a different context. This helps both the development team and the user. The developer team can gain better understanding of the concrete problem which is to be solved by a software system. When the system is finished, the user benefits from a intuitive usage model. For math-kit, we introduce the construction kit term as metaphor for our e-learning system.

To get a better understanding of this metaphor, think of a LEGO construction kit with all contained bricks. Mostly, the construction kit contains a construction plan for several models which can be built with the same bricks. But the special characteristic of the bricks is the patented stud-and-tube coupling system. This coupling principle allows stable models and a multitude of combinations — no matter how the bricks are colored, shaped, or sized. Hence, it is also possible to combine bricks of different construction kits in one model. Thus, the contained construction plan is a tiny subset of unlimited possibilities.

To make a connection between metaphor and planned software system we describe the demands and external circumstances. The main goal is the creation of a system that helps both students and lecturers to improve their work. Lecturers need pedagogic concepts and human intelligence to create reasonable content. The software market provides a lot of solutions which support content creation e.g. Adobe Framemaker, Microsoft PowerPoint, and Macromedia Flash. Most of these programs provide special functionality for specific problems and have weaknesses in other tasks. It makes sense to combine the strengths of all text, graphic, sound and multimedia tools. Therefore, we use the Sharable Content Object Reference Model (SCORM) (Dodds 2001) which defines a Sharable Content Object (SCO) as the atomic entity of a Learning Management System (LMS). Information about the contents of the SCO is
defined in extra data called Learning Object Meta-Data. The SCO wraps any kind of files, called assets, and can communicate with the LMS via a specified API. The SCO fits into our metaphor as the brick in our construction kit. The combination of several bricks or SCOs is realized through a separate mechanism called Content Packaging. The backbone of a content package is a manifest which defines the paths to the SCOs, additional meta-data and one or more structures of the built course. In contrast to the LEGO bricks, which include their own coupling system, the SCOs need the manifest as additional “glue”. Hence, in view of our metaphor, a built model or course is described by a content package. Every LMS that complies to the SCORM standard should be able to process the produced packages. The metaphor of the construction kit helps us to understand how course development, implementation and management should be handled by a technical system. Two cases still remain that are not covered. One problem is the design and implementation of well structured SCOs. As already mentioned, math-kit is a joint project and needs a strict separation of content and presentation to produce courses with a uniform appearance. The use of the Extensible Markup Language (XML) and the Extensible Stylesheet Language Transformations (XSLT) can help to force the wished separation (Farinetti et al. 2000). XML allows the definition of a specialized markup language with tags for mathematical content like formulas, definitions, and proofs. Such a restricted language helps the authors to concentrate on the content and hides unnecessary style details. The complete XML document can be transformed by XSLT into a wide spread output format like HTML or PDF. This approach has the benefit of a consistent and individual style of the whole course, even if foreign content is used.

Another problem not covered by the metaphor is the publishing of complete courses. A construction kit doesn’t support the replication and distribution of built models. Although, the LMS couldn’t fit into the construction kit metaphor, math-kit is a complete system for the distribution of mathematical content. However, our main focus lies on the development of an authoring tool for e-learning.

The Roles

We introduce roles to model the different views of our e-learning system. It is important to comprehend that one person can appear in several roles. The roles help us to model the static and dynamic behavior of our system with use cases and sequential diagrams (Bergner et al. 1998). This allows us to have a stringent and controllable development process. Math-Kit comprises six different roles: lecturer, student, composer, learning object developer, publisher, and administrator.

The lecturer uses single blocks or complete courses to extend his own slides or to create new ones. Individuals in the role student want to learn and can explore the entire database to use learning objects and courses of interest. These two roles don’t depend directly on the construction kit metaphor, because they work with their favorite LMS. Nevertheless, the construction kit is the foundation of the created content. The composer uses math-kit to combine existing learning objects to complete courses. In relation to the construction kit metaphor the composer defines the construction plan. The learning object developer designs and implements new learning objects. In view of the metaphor, the learning object developer creates the several bricks. In context of math-kit, the learning content is coded in XML with a structure for mathematics. This XML code has to be translated into a readable format by the role publisher. The last role administrator installs basic packages and software for the construction-kit.

Assessment and Outlook

The use of the construction kit metaphor and roles should support us in planning and developing an e-learning system for the creation and distribution of mathematical and technical content. The benefit of this approach is the natural connection between well known terms and a technical system. This makes the further development of the math-kit project easier. Despite this, one metaphor cannot cover all parts of such a complex software system. Hence, the metaphor has to be extended to meet the requirements. The next step will be a description of the system by use cases, sequential diagrams and an object model which paves the way for a later implementation.

Collaboration by Design: Creating a Course Explicitly for a Collaborative Environment

Michael Burke
Innovative Technology Center
University of Tennessee
United States of America
mburke@utk.edu

Abstract: In response to feedback obtained from recent graduates during a departmental program review, Dr. Janet M. Kelly, Assoc. Professor in Political Science at the University of Tennessee redesigned an upper division Urban Policy class explicitly on a technology enhanced collaborative education model. Taking advantage of a wireless laptop pilot project sponsored and supported by the Innovative Technology Center, Dr. Kelly used laptop computers, a versatile suite of software tools, and a customized course web site to create a technology-enhanced, collaborative Urban Policy course that addressed specific alumni recommendations for increased use of computing and communications technologies and team-based projects.

Introduction

“Our students are entering a world in which 60% of the jobs will require technological competency...[w]e must take advantage of the capacity of technology to...engage our students in active learning.” (Morrison, 1997). Transformations in business, social and educational institutions generated by technological evolution require that we address the demands for increased technological competency, collaborative working skills, critical thinking and rapid problem solving. This will require changes in the ways we prepare our students. “[T]oday's world demands critical thinking and on-the-fly problem solving. To meet these demands, our graduates require significantly different knowledge, skills, and abilities than our educational systems typically provide.” (Ellsworth, 1997) We need to provide problem-based learning opportunities that are both constructivist and collaborative. “[W]hat we should foster are academic environments in which students are free to explore and express their own ideas...to make explicit and elaborate on their own tacit knowledge.” (Watts, 1997)

The Case

Recent graduates in the Political Science program indicated that their initial experiences in the workplace revealed two significant weaknesses in their preparation, a lack of experience working with common computing and communications technologies, and a lack of experience working in project-based teams, Dr. Kelly set out to design a project-based course that would be collaborative in design, and would rely heavily on the use of computer-based productivity, communication and presentation applications. Dr. Kelly redesigned Urban Policy 410 to simulate a work environment in which students worked in teams to study actual urban problems, formulate policy statements and share their recommendations in a formal presentation. In addition to the expected discipline specific content learning objectives, she developed explicit objectives, assignments and assessment instruments for technology skill acquisition, written and oral communication, and group process skill development.

To meet each objective, Kelly used a variety of collaborative activities. All course materials, with the exception of the two required texts, were available online through the course website. These included the syllabus and general course information, course documents (including class lecture notes, a sample policy report and student policy reports, sample presentation and group presentations, evaluation guidelines and
Dr. Kelly grouped students into teams from the outset, and provided a set of guidelines and definitions for the roles to be performed within the teams. Each person in the group was required to assume a specific role within the group. Individuals had to 'apply' for their roles, and the group had some flexibility in role assignments and definitions within the guidelines provided. Each team was responsible for researching a specific urban policy area (housing, immigration, poverty, crime and transportation), developing a comprehensive written report, and presenting their findings to the class in a live PowerPoint lecture format. Research, writing and presentation skills were developed using guidelines and examples provided by the instructor. In addition, each student was required to use the specified evaluation criteria to evaluate the products (paper and presentation) of each group, as well as the process (group performance) of their own group.

In an interview at the conclusion of the semester, Dr. Kelly made the following comments:

"(During the program review) the graduates said that the biggest disparity in the graduate training in Public Administration ...was that when they got to the workplace, they worked with technology and they worked in groups. And that was the one way that we didn’t teach, we didn’t teach with technology and we taught everything on the basis of individual effort. And they had the hardest time trying to manage the assignments that they got in groups, without ever having developed any skills for working in groups, and especially working with technology. I built [the] course, integrating those two concepts, use of technology and group process to teach two skills that were very critical, but were not content related."

"Developing everything in advance, the assignments, the examples, the evaluation guidelines, everything, then putting it on the website is critical. The only way for this to work is that the answer to everything has got to be ‘it’s on the website.’"

"I would never go back to the old way of teaching this course, using only readings, lecture and individualized assessment...was spectacular...it was so clearly superior to anything I had ever seen from previous students in this course that I wouldn’t even consider going back to the old way of doing things."

Conclusions

The experiences with PS 410, including the design and implementation of the course website, collaborative activities, and assessment instruments provide inspiration and guidance to faculty and instructional designers in a variety of disciplines and educational settings. The careful application of collaborative learning methods, along with the integration of contemporary technologies, provide the foundation for more meaningful, relevant, and engaging learning opportunities for students regardless of their academic discipline or career aspirations.

Assessing the Use of Technology Resources in the College Classroom: Student Responses

In order to investigate the impact of technology resources for teaching and learning in an undergraduate classroom, a research project was conducted at Springfield College. Springfield College is a small four-year college located in Springfield, Massachusetts. For this study, two Elementary Spanish undergraduate classes were selected. One used technology to complete activities, homework, and expand on the aspects of culture studied in the class, while the other class used traditional textbook methods. Data collected demonstrates that technology is a suitable tool to increase motivation, participation and learning.

Implementation Method

This research study was conducted during Fall 2001 and a second study is being repeated this semester to strengthen and adjust findings, conclusions, and results. The classes were taught by the same instructor, using the same syllabus but one of the classes each semester was randomly selected to use technology as a means of academic instructional support. Approximately 20 students enroll in these first level Spanish courses; a foreign language course is a graduation requirement. Most of the students -- 80 percent --, have a fragile commitment to the class.

Students in the class using technology interacted with the worldwide web, email and chat rooms to complete activities and homework assignments. For each project, throughout the semester, students in the traditional class completed the homework activities in the exercise manual that accompanies the book. Each chapter in the book has a corresponding set of activities supplemented by the manual. The selection of web activities was designed to match the activities of the traditional class. The homework activities of both classes -- the traditional and technology class-- required similar amounts of time to be completed and they corresponded to the themes studies in class.

The students in the technology-enhanced class had access to course management software, the Manhattan Pilot, to check their grades, assignments and lectures, while the instructor kept a manual record and reported to the traditional class.

Assessment Method

Different assessment methods were used to understand the impact of technology in the classrooms. The percentage of completed homework was utilized as an indicator of student commitment to the class. To assess the effect of technology on learning outcomes, students' grades were compared. A questionnaire was developed to measure students' perceptions of homework activities. Open-ended questions were also added for students using technology about their impressions and reactions towards the activities.

Results

Learning Outcomes: Data reflect higher learning outcomes in the class using technology. (class average)

Students’ Impressions and Reactions Towards Technology

The narrative responses indicated that many students were excited by the fast feedback they received from the web activities and felt that it was an important supplement to the course. Technical problems such as a slow internet connection caused the most dissatisfaction but in general students were able to deal with occasional technical glitches.

Many students preferred the ACE Tests to the Web Search Activities. They mentioned that many of the Web Search activities were ambiguous and not as useful as the ACE Tests Activities. Two students recommended discontinuing them. Students were positive about the chat room activities. They mentioned that they usually turned to English while working in face-to-face activities but in the chat rooms they were forced to communicate in Spanish constantly.

Findings, Conclusions and Recommendations

The focus of many studies has been to analyze the impact of technology in terms of student achievement. When adopting technology to enhance the learning process there are many factors to consider. For this project, the courses were taught simultaneously. If course content, instructor and student population were all the same in theory, any differences should be attributable to the different teaching method utilized.

Students in the two classes using technology performed better than the students in the traditional classroom; for them, homework assignments were a positive experience. Students in the technology class pointed out that they benefited the most from the ACE Self Tests homework assignments because these web tests provided them with immediate feedback information on their performance.

ACE Tests —short for "A Cyber Evaluation" is a self-testing program that allows students to test their knowledge of topics covered in each chapter. Student answers are scored immediately, allowing students to correct their mistakes while working on the task. The complete activity and scores are submitted to the instructor. The strength of the activity is in its capacity for making self-assessment an ongoing and integral part of the curriculum. It reinforces instruction and guides students in reflecting upon their work. Even though the instructor kept manual records of the assignments for the traditional classes, there was a minimum of two days before feedback occurred. Students from this class declared that the feedback was never relevant for their learning. According to these findings, technology is a suitable tool to increase motivational learning.

For a practical matter, the traditional method was used as a base for comparison in this study. It is not the intention of this researcher to suggest the implementation of technology should replace traditional teaching methods. Rather it is my intention to suggest that technology’s main role should be to complement and further effective learning methods in ways not possible using only traditional methodologies.

The implementation of technology in the classroom requires time and effort from faculty who need to learn the new technology and design effective ways to integrate its use. With the incorporation of technology, traditional courses get redesigned. Under these new circumstances, teaching and learning is explored and innovatively re-created.
First Year of Technology Mentoring for Teachers and Faculty: Lessons Learned

Shirley Campbell and Songül Özdğül

Introduction:

Rapid changes in the available computer hardware and software applications along with continuous new releases of software applications have created a constant challenge for teachers who are trying to keep up with new technological improvements. In other words, in order to teach and facilitate their students' learning with the support of the available computer software applications as well as tools, teachers have to update their technology skills constantly.

Many schools acquired technology tools and software application to catch up the current technology applications in educational field, however, without proper in-service training of teachers, the use of these technology cannot be optimized. The current related to teachers' effective technology integration may be divided into following sections:

a) On-going training with rehearsal time: The teachers' technology training should include learning experiences that give them opportunities to practice the currently learned skills. Without practice, it should not be expected that teachers will go to their classrooms and will apply those skills.

b) Curricular approaches to increased technology use: The technology training offered to the teachers should include the situations that they will be using in their professional lives. Especially for novice technology learners, it is hard to make connections between the skills they are learning and how to integrate those skills into their teaching practice. Therefore, showing examples in some teaching related situations will inspire teachers and will lead them to think of more innovative ways to use those skills in their teaching practices.

c) Increasing comfort with the technology: Having an opportunity to practice the skills they have learned will increase teachers comfort level significantly. Once they have gained experience with new skills, they will be more comfortable sharing those skills with their colleagues and students while integrating them into their teaching.

d) Continuous technical support related to learning and using hardware and software: It is always frustrating for users to be stuck on a computer related problem and not be able to resolve it promptly. In such circumstances, if it is possible to get technical support in reasonably enough time, frustration will be diminished and the teacher dealing with the problem can productively continue his/her work. Prompt technical support is especially very important if the technical troubles arise in a classroom during the learning process. Unfortunately, this kind of prompt technical support is not usually available in many schools and settings. Anticipation of problems that won't be resolved in time to complete instruction reduces the likelihood that teachers will attempt to use it in their teaching. It creates frustration from the both the students' and teachers' perspective. Sometimes teachers even have to prepare the instructional materials in another format just incase any technical problem arises, so it doubles the work of teacher preparation. Available technical support offered to the teachers is a crucial factor in their decisions to use technology in the classroom.

The PT3 Project: Preparing Tomorrow's Teachers to Use Technology

The Preparing Tomorrow's Teachers to Use Technology Project was created by the U.S. Department of Education to address the need for newly certified teachers to be able to integrate technology in their first years of teaching. The U.S. Education Department's PT3 Program has provided funding for projects nationwide. At the School of Education at the University of Pittsburgh, a funded project is underway and is designed to address the issues of technology use and instruction for pre-service teachers.

The PT3 Project at the University of Pittsburgh focuses in part on the faculty and teachers who work closely with students who are working toward teaching certification. It involves increasing the integration of technology into the training offered to these teachers and faculty. The University of Pittsburgh received two separate grants: a Capacity Building Grant in 1999 to serve as a pilot, and an Implementation Grant to fund 3 years of implementation of the successful pilot beginning in 2000.

The PT3 Project at the University of Pittsburgh was designed to help teachers become users of each of four types of technology applications that are regularly implemented by teachers who are considered successful technology integrators. These four types are:

- Personal Use refers to using technology to increase personal productivity. The first application of the technology that teachers are likely to use usually related to technology training for their "personal use" of the technology. This refers to the idea that teachers' experience with technology tools and applications that produce results useful outside of the professional arena will help teachers significantly transfer those knowledge and skills into their professional needs.

- Classroom Management refers to the use of computer tools and applications to organize classroom information, record keeping, and to create professional looking products.

- Teaching Technology Skills to Students implies that before students can become involved in the activities that technology provides that promote higher order thinking skills, they have to be able to use the tools, and teachers have to know how to
teach the necessary skills. Students’ computer experiences vary from novice to expert in the same classroom because of their different backgrounds and exposure to technology. Teachers sometimes report difficulties providing satisfying answers to the technology related questions their students’ ask.

- Integration to Curriculum refers to the application of the use of technology to teaching in ways that increase learning and frequently require students to use higher order thinking skills. “Integration to curriculum” is significantly important in terms of teachers’ teaching experiences in the classrooms. Being comfortable using the available educational and commercial software programs and integrating them effectively into their teaching, teachers will be able to create more innovative and up to date as well as interesting learning experiences for their students that will facilitate student learning in more unique and resourceful ways.

The professional development package created for technology training for teachers attempted to expose teachers to all of these areas of technology use, but was also devised to prevent the difficulties that teachers often have when making attempts to use technology in the classroom. More traditional professional development strategies often are not as effective as expected in improving the implementation of classroom technology. Some components of the support developed within this PT3 Project include: collaboration and community that includes all school personnel, technology learning support in addition to technical support; cognitive strategies for technology learning; and the building of comfort and confidence. Within each of these components, several additional issues are addressed.

Features of the PT3 Project at University of Pittsburgh

This PT3 Project was constructed of a number of features, each expected to promote increased technology use by building skills and community. These features include On-Site Support Staff support, individually chosen projects, and whole group community activities with community building activities imbedded into each. Each of these features includes many activities to provide technology learning support.

On-Site Support Staff

Each teacher and faculty member participating in the PT3 Project at University of Pittsburgh was supported as they learned to use technology by On-Site Support Staff members. Teachers and faculty were provided very individualized support as they learned new skills and worked toward their own technology use goals. On-site Support Staff identified the types of skills participants needed to learn in order to complete the projects they chose, and adapted training very specifically to the needs of the learners. Also, keeping constant contact by e-mail and phone to remind the scheduled weekly appointments as well as the monthly meetings, had promoted teachers participation in these appointments and meetings.

The Support Staff also held mini-workshops that participants were invited to attend. These workshops were non-traditional, in that they were expected to serve fewer than ten attended at a time, and the covered only specific skills during the one to one and a half hour meetings. Support Staff often focused the workshops specifically to the needs of the individuals attending, and invited those individuals who would benefit from a specific skill areas. The Support Staff were skillful in finding different ways of presenting the same instruction including supporting handouts, examples and hands-on practice until the teachers became comfortable doing the tasks alone. They used these techniques when working with individuals as well as in workshops. Many of the workshops were scheduled at times when the Support Staff felt that a number of individuals would benefit from learning the same skills.

In the on site training sessions, teachers from two schools were initially provided support individually with plans to work as small groups later on. In the third school, teachers’ on-site support was provided in a small group format from the start. The teachers who were being helped individually were resistant to joining together with other teachers when meeting with Support Staff, and tended to want to continue to work individually. Based on this difficulty in community building, On-Site small group support is recommended instead of solely individual assistance.

Individually Chosen Project

Each participating teacher and faculty member in the PT3 Project was required to choose a realistic project, called the individually chosen project, that could be applied in their own classroom. The projects were required to meet two guidelines: they had to be related to classroom work, and they had to be projects that required the teacher to add to their own technology skills in order to complete them. Depending on the skill level of the teachers at the onset of PT3 Participation (which ranged from none to quite proficient), the individually chosen projects could be well integrated curriculum enhancement projects to be implemented by students, or they could require that only the teacher use the computer, while becoming more comfortable with their own technology skills. Allowing each individual to choose a project rather than assigning projects gave each individual ownership of their own learning, and allowed them to choose a project that they felt would be useful.

One of the most difficult aspects of the individually chosen projects for the participants was committing to a project that they did not have the skills to complete. Much reassurance was required on the part of the On-Site Support Staff that projects were expected to be revised over time, as participants became more familiar with the technology and its implementation. As a result, many projects changed between the time that they were chosen at the beginning of the school year, and at time that they were implemented.
Another result was the reaction of pilot year participants to the discomfort of new participants in the first full year of the grant. Experienced participants reassured the newcomers that they should choose a project that they found exciting, and not concern themselves with how they would eventually produce it: there was enough support and flexibility to make it happen. Also, their technical support person would be helping them to achieve their goals and providing them with the required technical skills so that they would be able to complete their project.

The teachers were encouraged, but not required, to work collaboratively with other teachers on these projects. The On-Site Support Staff who assisted the teachers at times suggested matches between teachers with similar interests or complimentary skills, with the expectation that these teachers would eventually begin to see one another as resources. Although no teachers chose to work collaboratively on a project during the first year, a number of collaborative projects emerged during planning for the second year. The On-Site Support Staff encouraged collaborative projects with expectations that these efforts would help to increase problem solving and promote an increase in confidence for participants. Long term effectiveness of the PT3 Project is also based on the building of strong and supportive learning communities among peers, allowing growth to continue long after funding is finished.

Whole Group Community Activities

All participants of the project were required to take part in activities that were intended to bring the group together, with the expectation that sharing would support the likelihood of the formation of a community of technology users. Several different types of meetings were held. Monthly meetings were held on Saturday mornings, and activities promoted interaction between participants related to technology use and education of students. Participants were given opportunities to talk about successes as well as difficulties, and were involved in activities that promoted discussion among individuals. Many expressed appreciation for opportunities to become familiar with teachers from other schools.

Two other whole group activities promoted through this PT3 Project included Summer Camp, and Celebration of Successes. During Summer Camp, participants were involved in community building activities alternated with technical skill building and activities to develop skills in technology integration. As often as possible, sharing was expected and encouraged. Summer Camp was held at the beginning of grant activities, and Celebration of Successes was the culminating activity of the PT3 Project for the school year. During the Celebration of Successes, each participant was asked to present the individually chosen project that they completed during the school year. Presentations were to include not only descriptions of the projects and impact of implementation, but also barriers faced and solutions found, and personal successes involved. All participants expressed appreciation for the opportunity to present their own work, and see the work of others. "And the project[s] demonstrated at the Celebration of Successes on the final day of the program [were] fashioned from hard work, cooperation, innovative ideas, comfort with manipulation of the technology, and effective implementation the technology in their classrooms" (Campbell & Özgil, 2001).

Our findings at the end of the first year of the project period showed that teachers and faculty members preferred to plan and work on their projects alone. However, on celebration day when they were presenting, sharing and discussing their projects with the others we have observed that teachers from different schools came up with different ways of using their colleagues' projects in their schools or they came up with combining their experiences together in order to create new, innovative, and collaborative projects to be accomplished in the second year of the project. Because of their improved technology skills level as well as the satisfaction of what they had already accomplished, they were more confident, enthusiastic, and creative and also willing to share and work collaboratively with the other teachers to create better products.

During the planning of the PT3 Project, district level administrators were involved in planning project structure and activities. They were responsible for informing administrators at all school levels, and PT3 Project staff contacted school-level administrators only individually prior to an administrator's meeting arranged several months later. This was a golden opportunity for the PT3 project staff to present and discuss the goals and possibilities of the project with these administrators. Until this meeting, administrators were aware of the PT3 Project and were encouraging their teachers to participate, but this communication between the administrators and project staff as well as among the administrators gave everyone a chance to grasp the scope of the project in detail as well as gain realistic views of seizing the opportunities given by the project.

An administrative meeting was not only beneficial for opening communication with Project Staff as well as among administrators themselves, but also beneficial in resolving several issues which their teachers were encountering in their attempts at effective use of technology. First of all, administrators showed sensitivity to allocate time to project participants to work with their support person on technology training activities, especially weekly meetings at either their school or at the PT3 Project community gatherings. Also, administrators addressed some hardware and software limitations and problems that teachers encountered in their schools. Administrators were also better able to affect teachers' success because reports made available to them by the PT3 Staff provided more information about difficulties teachers had in implementing technology uses. Consequently, having better understanding of teachers' problems with technology, then sharing and discussing these issues with the other schools administrators, inspired them to deal with their teachers' difficulties.

In addition, once the school level administrators were fully aware of the possible impact of the PT3 Project in their schools, they encouraged the teachers in their schools who were not already participating to become active in the project. Participating schools then welcomed PT3 activities in their buildings.

Findings

During the course of the pilot year of the PT3 Project at University of Pittsburgh, several strategies for increasing technology learning and community building were tested, and results were noted. Promising strategies and components identified by teachers as most effective in helping them to reach their technology goals are noted.
Journaling (Learning Log)

Participant teachers were required to keep a reflective journal whenever they used technology applications. The reasons behind the requirement of journaling were two fold. Journaling was beneficial to both the project staff and the participants. Journaling was seen by Project Staff as an opportunity to gain feedback about the provided training as well as track the progress of participants. Feedback gathered from participant journals was used revise the design and implement the training according to entries. While many of the participants did not enjoy journaling, those who did described it as a reflective tool, providing them an opportunity to reflect on their experiences in using technology. It was also served as a means for participants to document their experiences with technology.

Journaling was also a requirement for the Project Staff. At the end of the first year of the project, Project Staff reported that journaling was a very effective tool for both keeping track of the progress of several teachers that they were assigned to work with, and also preparing for teachers' different training needs. They were also able to use their journals as logs, to identify practices that they use that were particularly effective, and to document their own growth over time.

As a result, journaling was considered an important tool that contributed to following the progress of the training and adapting it as needed. Because of its benefits to the overall project, it was required of participants in the following years of the PT3 project as well with some modifications. During the pilot year, journaling was done on a notebook and these reflections were copied and given to the their onsite Support Staff. In the following year, journaling was planned to be done on-line.

Note Taking

Note taking plays a very essential role in teachers learning technology skills, especially novice teachers. If these newly learned skills are not practiced frequently, they could easily be forgotten. To prevent that, the teachers and the faculty members were provided with handouts about the instruction. Many times the teachers and faculty personalize the steps by adding notes to the given handouts, and using these notes increased the likelihood that they would be able to practice the same skills successfully on their own. When they had difficulty recalling the skills they had learned, the personalized notes served to refresh their memories. When applications shared similar sets of keystrokes or menu options, creation of handouts that repeated the same formatting for such items served to jog the memory and helped to make connections that transferred application of the skills.

Concept Mapping

Sometimes it is very difficult for teachers and faculty who were novice computer users to understand how the skills they have been learning are related to their final projects. Using concept mapping as a cognitive strategy gave them a visual tool for conceptualizing the relationship between the each group of skills needed to be learned and the relationship of those skills to the main goal. Therefore, the opportunity of seeing visually which skills are required to reach the goal, what they have already learned, and what still needs to be learned helped both the Support Staff as well as the teachers to plan the best sequence of learning activities.

Comfort and Confidence

Teachers were supported in many ways to reach their goals for the end of the first year of the PT3 project. For example, flexible technical support, opportunities to gather the projects participants in workshops as well as monthly meetings, and having the flexibility to alter the final projects were important key elements in increasing the teachers' comfort level with working for their goals and with project staff. Additionally, seeing the final projects of the previous years’ participants, as well as listening to their experiences, increased the confidence level of the teachers participating in the project in the second year. Therefore, it was assumed that the anxiety and the disappointment that the first year participants encountered would be somewhat reduced for participants entering in the second year.

Technology Learning Support

Much of the success of the first year of implementation of the PT3 project was attributed to the availability, flexibility, technical skills, and knowledge of good tutoring practices of the technical Support Staff. A number of teachers had difficulty scheduling meeting times during their busy daily work routine. The flexibility of the technology Support Staff made it possible to schedule time slots that meet the schedules of the teachers. As state earlier, it was very important to maintain contact with participants between meetings, by email or phone.

Participating teachers mentioned in their evaluation forms that one of the greatest assets of the project was the On-Site Support Staff members' enormous patience. They were willing to repeat the same instruction many times when teachers needed them to do so. As mentioned earlier, the On-Site Support Staff were very creative in finding ways to present the same information in multiple ways.

Individual Classroom Projects

Participating teachers and faculty members were required to choose an individual project at the beginning of PT3 Project participation. They were expected plan it, including modifications, then present it at the end of the year. These chosen projects could reflect any subject area(s). Projects required that participants learn new skills as they created the projects, but the only software and hardware restrictions were those imposed at their schools sites, usually based on availability. Their anxiety and disappointment were resolved by comforting them that the final project requirement was meant to have them to experience from the beginning of the project how to plan, develop and design, evaluate and redesign their final projects and support them along the way. Also, their technical support person would be helping them to achieve their goals and would be providing them with support to learn the necessary technical skills to complete their projects.
Summary

From the implementation of the PT3 Project, many lessons were learned that can be used to increase the technology learning of teachers and faculty. The following list summarizes the discoveries described here. In this section, the term learners refers to the educator who is attempting to learn new technology skills and increase technology integration.

- On-going training should be provided, both technical and technology learning support, and should be flexible and individualized.
- Support provided for long term learning should include regular follow up and contact with learners - via email or phone when not in person.
- Manuals and reference documents should be provided when learners are working independently.
- Note taking done while learning to use hardware and software is often useful for learners when working independently.
- Learners should be provided concept mapping tools, and taught to use concept maps and other visual tools for project planning, time management and for setting and achieving goals.
- Learners should be provided opportunities and encouragement to work in groups right from the start, and be discouraged from remaining separate, even during informal training.
- Maintain contact with building and district level administrators to get them involved and excited, and keep them informed.
- Experienced participants should be encouraged to share their successes with new group members.
- All projects that learners are expected to undertake should be relevant to them.
- If taught to write reflectively, learning logs can be very useful.

Any professional development project should look closely at the needs of its community members, and consider which items can be applied most successfully. In the creation and implementation of University of Pittsburgh's PT3 Project professional development program for teachers, discoveries were made that could be useful in helping to avoid difficulties and identify areas of potential weaknesses. They can also be used to identify strengths that can increase probability of success.

Abstract. A teaching experience merging many collaboration strategies and e-learning activities is presented. It has taken place at the University of Lugano (Switzerland), and involved 33 undergraduate students attending the course “Advanced Enterprise Applications of Information and Communication Technologies” in the Faculty of Communication Sciences. The experience – actually, a role-play – consisted in developing an online course on business models on the web (a course freely available online), and showed how an hybrid approach can help integrate online activities and other academic teaching strategies. The results of this activity are discussed, as well as some ideas for future experiences.

Setting the scene
The Lugano University (USI) was born in 1996 and is the most recent Swiss University and the only one in the Italian speaking part of Switzerland (Koenig 2001). USI hosts a Faculty of Communication Sciences that offers four different curricula: Mass and new Media Communication, Corporate and Institutional Communication; Technologies for Communication and, since 2000, Communication in Educational Settings. While, at first, degrees were awarded after four years, the University has adopted the 3+2+3 model following the European Union standards (since the academic year 2001-2002). Students come from Switzerland, Italy, and many other countries; their mother tongues are mainly Italian, German, French and English, and courses are taught in Italian as well as in other languages.

This paper presents an experience done during the first semester of the academic year 2000-2001, with students of the fourth year (from the curricula Corporate and Institutional Communication and Technologies for Communication) attending a course called “Advanced Enterprise Applications of Information and Communication Technologies”.

Students were supposed to attend lectures and to work in small groups at different projects concerned with the course topic: 11 groups were involved in the project that is now to be presented.

The roles and the play
The exercise consisted in a role play: students pretended to be members of an international consulting agency (one of the top ten in its field), and had to build up an online course for their colleagues junior consultants, in order to make them aware of the many possibilities for (as well as constraints and shortcomings of) online business. Junior consultants attending the course had not to become experts in the field – the company already had those experts: namely all the people involved in the role-play – but only to become capable of understanding, when doing their consulting activity, if there was any room for online business.

The course had to be in Italian, for self study, and all the materials should be covered in not more than 24 hours (three working days). The platform for course delivery had to be WebCT®, while all the

1 Institute for Communication and Education and Doctoral School NewMinE: New Media in education – www.lu.unisi.ch/newmine.
2 TEC lab: Technology Enhanced Communication Laboratory – www.lu.unisi.ch/tec-lab.
3 The course was held by professor Paolo Paolini assisted by Lorenzo Cantoni, who designed and led the experience, and Davide Bolchini.
involved groups had to collaborate also using the University's intranet and a tool for online discussions (WebBoard5).

Course developers were divided into three different types of groups: a. management and reporting: one group of three students, randomly chosen; b. pedagogical design and technical implementation: two groups of two students each, selected because they were more expert in the use of technologies and had previously attended a course on how to use the WebCT platform; c. content development: eight groups of three students (randomly chosen) were assigned a different business model according to a taxonomy of Internet business models proposed by Mike Rappa (2000): 1. Brokerage, 2. Advertising, 3. Infomediary, 4. Merchant, 5. Manufacturer, 6. Affiliate, 7. Community, 8. Subscription and Utility.

Students were briefed during a lecture, they were also given a detailed printed timetable of the exercise, with all the group assignments6:

Group a. was in charge of: supervising and monitoring all the other groups' activities, promoting them, reporting to the role-play master, being an interface between him and all the other groups, doing a weekly report of about 5 minutes during course's lectures, defining a suitable conference structure for online communication via WebBoard. The group had also to write a short introduction to the online module, in which the course and Business Models were defined and introduced. Group a. had periodical (usually once a week) meetings with the role-play master.

---

6 The exercise started the 30th November 2000 and ended the 8th February 2001; only working weeks are considered in the table.
Groups b. had to firstly define guidelines for all the content development groups on how to package the materials they had to prepare (e.g. document length, format and style), and to design, implement and test the prototype course.

Groups c. had first to research their specific topics (starting from Rappa’s website and looking for relevant literature, both online and offline). Students were asked to perform their research as a kind of webquest (Clarke 1990; Dodge 2001), and select relevant references from the results. Moreover, groups c. had to write a suitable text explaining the features of the assigned business model (output 1). Groups c. had also to deliver a slide show to briefly present the subject, and to write two case studies of online applications implementing the business model (output 2); in addition to that they had to create a self-assessed test that could enable the learners to test their understanding of the contents covered by the module (output 3). All the three outputs were, in turn, input for groups b. All the materials had to be written taking into account that an average learner (a junior consultant, with an experience similar to that of the students) should cover every module in no more than three hours. Each content development group was introduced to the key features of the assigned business models by the role-play master in a kick-off meeting. The meeting allowed the group members to acquire the conceptual elements to interpret the large amount of literature available on the theme.

Rehearsing and performing

All the groups worked hard, and produced their output on time. Group a. organized – after some trials – 13 different online conferences on WebBoard: 11 devoted to every group, and used by its members for their internal communication as well as by the management group to post messages to the single groups. The remaining two conferences were titled “General” and “FAQ” and were used by group a. to give general instructions and information, and to sum up organisational topics of common interest. Except for the FAQ conference, with 5 messages, all the others got from 16 to 45 messages (mean value: 28). The number of messages posted on the WebBoard for each conference is shown in Figure 2. Groups b. and c. had to post and update a “state of the art” message on their own conferences, where they summarized weekly what they did (acta), what they were going to do the following week (agenda), and if they needed anything from group a. (quaerenda). The weekly state of the art reported the essential information needed by the management team in order to have an overview on the state of the project and to coordinate and plan the work in parallel of the nine groups. As any of the groups failed to publish the state of the art (or it was too vague and generic), the managers posted a message in the group conference to eagerly solicit to deliver the expected report. People of groups c. interacted very well in each group, but did not show much interest in what the others were doing (anyway, they were informed regularly by group a.). Rich communication flows were established between group a. and all the others, and between groups b. and groups c. Figure 2 shows the number of messages posted within each conference on the WebBoard.

Many communication exchanges took place in the real world: students met almost every day in the university, but at the same time a lot of communication was also carried out via the WebBoard, sometime just summarising what was already said/discussed/decided in face to face communication exchanges (hence making group members sure that they all shared the same knowledge and the same decisions). Besides WebBoard, also email was used for coordination and communication among group members. For file exchanging the university intranet was used: so there were not any upload/download problem for groups b. that implemented and tested all the course.

The online modules showed that students had learned quite a lot, and were able to communicate their knowledge in a format suitable for an online course. Not all students delivered the same quality: some modules were better than others in terms of content accuracy, wording style and rhetoric effectiveness. However, the overall quality of the course was good.
Due to the quality of the product, it has been later made freely available online at the following location: www.lu.unisi.ch/tec-lab/courseware.htm. The facility of having the module content both in textual form and in slide-style format turned out to be very fruitful. In fact, the course modules have been effectively reused later for other courses and workshops organized within the Faculty (about online business models and electronic commerce), which needed both slide presentations and text handouts.

The flexible structure of the module allows to learn a business model from different perspectives and according to different levels of depth: the text explains in details the roles and the relations defining an online business model (with its variants and sub-models) pointing out benefits and drawbacks; the case studies illustrated practical implementation of the model in a current web application; the slide show serves mainly for revision.

Figure 2: Number of messages posted on the WebBoard for each conference.

Pedagogical considerations and ideas for future experiences

The project allowed the students to learn about online business models by designing and creating an online course on that topic: this was a sort of loop-input, i.e. the actual correspondence between the content taught (advanced applications of ICT) and the way it was learned by the students (designing an e-learning activity). The main benefit of the described loop-input strategy is that students could live two kinds of experiences at the same time (collaborating in creating the online modules and learning about online
business models), both strongly relevant to the core topics of the academic course. The two experiences are strongly correlated and support each other, enhancing the effectiveness of the overall learning experience.

Moreover, this experience helped combine a number of collaboration strategies and technology assisted learning activities: 1. computer assisted collaboration (communication exchanges between work groups mainly by means of WebBoard and University intranet); 2. web-based distributed learning (the online modules delivered); 3. meetings and lectures (between the role-play master and each work group; between work groups and the managers; between work groups and the design groups); 4. webquests (for searching the relevant material to be put in the references of the module); 5. classroom discussions and presentations (at the end of the project each group presented the work to their colleagues and the academic staff); 6. a constructivist activity has been merged with academic teaching, leaving to all "stakeholders" the possibility to contribute as much as they could to the common knowledge; 7. e-learning activities have been integrated inside a more comprehensive framework, and not isolated as sometimes happens when adopting the "Manichean" point of view: “face-to-face vs. online” (Rowley, Lujan & Dolence 1998; see also Cantoni & Paolini 2001); in particular, 8. also a lively relation with the professor and the assistants took room as a milestone of the learning experience (Dufeu 1994).

It could be argued that in a similar organization of the role-play — where the collaboration between groups of students is a necessary condition for the success of the project — the failure of one student group (e.g. no output delivered on time, no communication with other groups, no respect to the management guidelines) could cause the crash of the entire project. Actually, this was not the case: the project organization took into account this possibility. Even if any of the 8 groups of students responsible for the content development had failed, that would have not stopped the project, which would have still delivered a running online course (but with a module missing).

The problem would have been harder if the pedagogical-design and implementation groups had failed the job (other students with similar technological skills were difficult to find). In case of failure of the management group, that could have been replaced by the role-play master. The robustness of the project organization was due to the fact that the content developers groups could work in parallel because the content modules had minimum or none overlapping.

One year after the end of the course, students who were involved in the project were asked to give their feedback through a simple questionnaire. Among the positive aspects of the project experience, students mentioned that they learned concepts underlying online business models; learned how to use a collaboration tool like WebBoard; combined in practice technology with education; learned how to define precise guidelines for content developers; performed a creative activity; lived a new class experience. Moreover, students appreciated that the members of the management group were colleagues (peers) and not the professor/assistants. Respondents pointed out also weak points of the collaboration experience, such as the fact that some content development groups were not interested in the work of the other groups; on the other hand, intra-group collaboration was evaluated as very effective. Some students said that the time frame of the project was too long with respect to the final result delivered; others claimed that there was not enough time to complete an in-depth reflection and research for the content of the modules.

The questionnaire had seven main questions. Nine students filled in the questionnaire. Following charts (Figure 4 and Figure 5) show the marks expressed by each of the nine students for the two most relevant questions, the first about the perceived effectiveness of the collaboration within the group, and the second about the perceived learning outcome. The scale used was a five points scale measuring the level of agreement (1: not at all; 5: at all).

**Question 1:** Was the collaboration within your group positive and useful?

**Question 2:** Do you think you got a useful insight in the theme of Web Business Models?

For the majority of the students involved, it was the first time that they experienced such an innovative project in a class. Only some of the students had experienced something similar (at a smaller scale) at the WebAtelier of the Faculty of Communication Sciences (a web design lab led by Lorenzo Cantoni, www.webatelier.net). Each term, at the WebAtelier a half-dozen web applications are designed and produced by groups of three students. Clients are public and private companies in Switzerland and Italy. While the WebAtelier offers a lively and realistic working experience, the project presented in this paper has two important additional features: it allowed the students to learn about the content of the application (web business models) and to collaborate in a larger project (31 students instead of 3).
In the term starting in November 2002, we would like to perform a similar project. One of the lessons learned from this experience is to select properly the students and assign them to group according to their competence and management ability (instead of randomly). The learning outcome of the class could also be improved in the future by verifying that the pedagogical-design and development groups have enough time to learn the topic of the course, without being overwhelmed by the time-consuming implementation activities.

The project was exciting both for the students – who were committed to the responsibility of coordinating the work and learning the materials for delivering a complete running application – and for the teachers – who could see week after week the success of an innovative educational experience. The counterpart – on the teacher side – was the amount of effort required for the preparation of all the details of the activity (project schedule and possible breakdowns) and the monitoring of the project (managers – who represent the potential weak ring of the chain – had to be followed step by step).

A Classification of Document Reuse in Web-based Learning Environments

K. Cardinaels, H. Olivie, E. Duval
Dept. Computer Science
Katholieke Universiteit Leuven, Belgium
{Kris.Cardinaels, Henk.Olivie, Erik.Duval}@cs.kuleuven.ac.be

Abstract. The last few years, Information and communication technology (ICT) has been introduced in education at a very rapid pace. Large amounts of resources (time and money) are invested in the development of educational resources, to be used in the new learning environments. Reuse of existing material is often cited as an approach to reduce the investments involved. Several research projects focus on the management of educational content, often by associating metadata to the resources. Research about the reusability of documents is much more rare, because it is much more difficult. In this paper we report on our research on reusability of educational documents. This is part of a PhD research in the context of ARIADNE. We have investigated different educational environments, focussing on the type of documents that are typically used. We have developed a classification of document use, based on four questions: how, when, who and what.

1. Introduction

One of the main goals in research on learning objects is to enable reuse technically. The focus is often on the development of a management system for educational documents and their metadata. Users can search learning object repositories for relevant content and reuse it in their courses. An example of such a system is the ARIADNE Knowledge Pool System [ARIADNE 2000, Duval et al. 2001]. Enabling reuse technically, however, is only one side of the medal; designing for reuse (i.e. producing reusable documents) is the other. Depending on the context, a document can be more or less reusable for a certain course. Much less attention is paid to this aspect in research.

Reusability aspects can be divided into two different groups.

1. In [Barrit 2000] the CISCO reusable learning object strategy is presented. This strategy focuses on how a typical document should be compiled from smaller units to form a new reusable object.

2. The other issue considers the type of document, its adaptability, teaching style, and so on.

In this paper we report on our preliminary findings on the reusability of educational documents. We consider different didactical contexts and look for properties a document should have to be reusable in that context. In the first section we define the different contexts we consider for study. Then, we look at how documents are reused, by asking four questions about the reuse. How are documents reused, who selects the documents, when are they selected and what is reused?

Reusability is also strongly influenced by the metadata for the documents. Clear and precise metadata helps the instructors to retrieve appropriate documents. In [Cardinaels et al. 2002] we focus on automatic metadata generation for learning objects. In this paper we focus on the documents themselves.

2. Pedagogical Environments and Approaches

In [Janssens et al. 2000] three different learning environments are described that are applicable for different learning goals. A learning environment defines how the content is handed to the learners and how those learners can reach the goals of the course, based on their knowledge and possibilities. In each environment, the teacher can choose between different approaches, depending on his preferences and the goals of the course. In this section, we briefly discuss the different environments and approaches.

1. The first environment is an information environment. In this environment, the focus is on providing external or new information to the learner. The learner should process this information, by memorising it, giving it a meaning or applying it in other situations.

The pedagogical approaches for this environment depend on how the information is provided to the learner, which medium is used to 'store' the information. The authors distinguish between five work forms for this environment:

i. lectures,
ii. written material,
iii. video and documentaries,
iv. hypertext and hypermedia,
v. world wide web.

In our discussion the distinction between written material, video and computer-based material isn’t important. This kind of environment mostly relies on so-called ‘expositive’ learning objects [LOM 2001].

2. The second environment is an interaction environment. Here the learners interact with each other, with the teacher or computer programs. The result not only depends on the individual learner and his activities, but mainly on the cooperation with the environment. It isn’t important whether the interaction is issued using some medium or not. Janssens distinguishes between the following pedagogical approaches:
   i. discussion,
   ii. computer-supported education,
   iii. collaborative work,
   iv. computer-supported collaborative work,
   v. internet-supported collaborative work.

Document reuse in the last three forms is minimal, mainly giving an exercise to the learners. From our point of view, we can group these forms together with the first work form, discussion.

3. The third environment is the action environment. Its goal is to train cognitive skills of the learners. As in the interaction environment, the emphasis is on active participation, the initiative, however, must mainly come from the learner himself. This means that the learner works mainly individually and he guides the learning process himself. Typical work forms for this environment are:
   i. assignments,
   ii. simulations,
   iii. computers as a tool.

This kind of environment mainly relies on so-called ‘active’ learning objects [LOM].

3. Characteristics of Document Reuse

In this section, we look at the different environments and investigate how documents are reused. This will help us to define characteristics for the reusability of documents in a specific context. We consider four questions about the reuse of documents:
1. Who selects the documents that will be used?
2. When is the selection performed?
3. Which types of documents are reused?
4. How are the documents reused?

In question (1) we distinguish between automatic reuse and manual reuse. An automatic reuse system is a computer-based environment in which the computer selects the documents automatically from a pool or repository. This selection can be based on the learner’s capabilities (as in a learner model) or on prescriptions provided by the instructor (as in a pedagogical model). With manual reuse, the instructor selects the documents manually from the pool.

The main difference for reuse requirements on learning objects relates to the descriptions, i.e. the metadata. An instructor performing manual selection can both examine the document contents and interpret the metadata; a computer application can only look at formally provided metadata. Of course intelligent document analysers could study the content itself but it is very difficult to interpret the difficulty of the document, the time it takes to study it, and so on.

Note that manual reuse often takes place without explicit use of a reuse system. We call this silent reuse. The World Wide Web is a practical resource for demonstrations, simulations and so on. These are made available for internet users and can easily be reused in courses. This type of reuse is opposed to explicit reuse through reuse systems. Of course, storing documents for explicit reuse facilitates searching, retrieving and using documents. Explicit reuse enables specific queries with pedagogical metadata parameters [Duval et al. 2001, Duval et al. 2000].

In question (2), we focus on when the documents are selected for reuse, or, more specifically, when the decision to (re-)use a certain document is taken. Again, we recognize two extreme situations. The first is an a priori
selection of documents. This means that all documents are selected before the start of the course, or at least before the system knows about the learners. In the other extreme the documents are selected at runtime, just in time to be displayed to the learner. In the latter situation, the system, being a computer application or the teacher, can consider knowledge about the learners to select the appropriate documents.

The third question asks about the type of documents that are reused. Are the documents always rather large, like a slide set, or a complete textbook? Or are the documents very small, handling one specific topic. An example of such small documents can be found in a questionnaire system in which single questions are selected to compile a test.

The last question, but maybe the most important one for the reusability aspect, is about how documents are reused. From the point of view of the re-user, the easiest and most powerful reuse type is as-is. In this approach, the document is retrieved and integrated in the course without any modifications. More likely, however, is reuse with some degree of modification. Such modifications can range from technical adjustments, for example changing the background colour, to semantical changes like changing the vocabulary (e.g. mathematical symbols). Another form of reuse that is applied often is based-on or indirect reuse. With this term, we indicate the creation of new documents that are based on other documents. From the reuse perspective this reuse probably is mostly overlooked, but it certainly is reuse. To create a learning object, several such objects are consulted (cfr. the bibliography in texts) to compose a new document fulfilling the needs for that specific course.

Why a certain document is reused, with or without modifications, or only as a source of inspiration, also depends on didactical aspects and the learners. Considering the knowledge of a group of learners, a document can be appropriate to use. For another group the same document, in the same didactical context might not be suited for reuse directly. Maybe the document should be extended with more examples, or can be summarized to a denser document.

4. Document Reuse in Different Environments

In this section, we combine the knowledge about the different learning environments and pedagogical approaches with the different types of reuse. For each pedagogical approach, we indicate the most likely types of reuse for the four questions. Table 1 depicts the result of this exercise.

Table 1: Document use in different educational environments and work forms

We now discuss some of these pedagogical approaches, through specific examples. The different pedagogical approaches we describe are:

1. Ex cathedra lectures
2. Intelligent Tutoring Systems
3. Questionnaire systems

Of course, these three are only examples to clarify the questions asked above.

1. With ex cathedra lectures we refer to the more traditional teaching environment, in which the teacher explains theory. The learners mainly listen to the teacher and follow in their textbook or presentation slides, making notes where necessary. This pedagogical approach in fact is a combination of lectures and written documents.
For the lectures, the instructor typically selects a textbook before the beginning of the course and uses this as a basis. Examples, definitions, etc. are taken from the book and used without serious modifications. Other reference material is being used as a basis for new material. The reuse is thus both "as is" and "based on".
The handouts and other material that students receive are mostly directly related to the lectures. So, these documents are also created from base material and other modified documents. All the material is selected before the start of a course, or at least without knowing much about the learners.

2. Research on reuse in intelligent tutoring system (ITS) mainly focuses on reuse of active modules or program modules to make the system intelligent and adaptive to the learners [Sarti et al. 1995]. Our interest goes to the reuse of the documents. One of the main problems in adaptive systems is the amount of material that is needed to serve all the different learners. Each learner at each moment in time should receive a document that is suited for his knowledge about the topic at hand, his learning style, etc. The document pool in these systems must contain a large set of learning objects to be effective. The adaptation to the learners in an ITS is performed by the system itself. As a consequence, the system must choose the documents presented. The system selects the document at runtime, based on information it gathered previously. Of course a system cannot change much to a document, except for maybe layout and ordering in specific applications; this implies a literal or as is reuse.

3. The third system we briefly describe is a questionnaire system. In such systems, a template for questionnaires (exams, multiple choice questions...) is defined by the instructor and the system instantiates it with questions. These questions are selected from a repository and used without modification (except maybe for layout changes).

5. Conclusions and Further Work

In this paper, we presented the preliminary findings of our research on reusable learning objects. Our point of interest is not so much how documents can be reused, but mainly how it can be ensured that a certain document is reusable in a specific course. A developer only benefits from the reuse if it doesn’t cost (in time, money, etc.) more to adapt and reuse a document than to create it from scratch. Unfortunately, reusability depends on a multitude of parameters, such as the pedagogical approach, the system being used, the information known about the learners, and so on.

We started with an analysis of different didactical environments and pedagogical approaches. For each environment, we asked who selects the documents, when the documents are selected, how they are reused and what type of documents is reused. Most courses in this environment are guided self-study courses, with a mixture of lectures and on-line resources.

Clearly, this research is only at the beginning and many questions remain unanswered at this moment. Topics we will consider in further research are guidelines for building courseware, extensions of the LOM metadata for reusability aspects, style checkers for on-line courses concerning their consistency (audience consistency, presentation consistency...).

Looking at the interest for learning object 'pools', we can conclude, however, that there clearly is a need and demand for reusable courseware. Enabling search and retrieval through metadata is only a small step towards reuse.

Issues in Automatic Learning Object Indexation

Kris Cardinaels, E. Duval, H. Olivie
Dept. Computer Science, KULeuven, Belgium
{kris.cardinaels, erik.duval, henk.olivie}@cs.kuleuven.ac.be

Abstract: Acquiring a critical mass of pedagogical elements is a condition sine qua non for reuse. One of the main obstacles to attain a large amount of documents is the difficulty in creating associated metadata. Accurate metadata contain a considerable number of attributes. Assigning correct values to each of these attributes is a tedious task and few users are willing to invest considerable time to do this. Automatic indexation of learning objects could solve this problem. Furthermore, it could help to create more consistent metadata. In this paper, we discuss several issues for the development of an automated indexation system for IEEE LTSC Learning Object Metadata.

1. Introduction

The success of educational metadata strongly depends on the willingness of teachers, authors or other users to provide their pedagogical documents with accurate metadata. Indexing learning objects, however, is a tedious task and an extra burden. Automatic indexation tools could overcome this problem and increase consistency and quality of metadata.

In this paper we discuss three different approaches to automatic metadata generation: profile-based indexation (section 2.1), document properties analysis (section 2.2), and similarity search (section 2.3).

In the last section, we briefly discuss a framework for automatic indexation that combines these three techniques. We are developing the framework in the context of the ARIADNE Knowledge Pool System [Duval et al., 2001].

2. Different Approaches to Automatic Indexation

In this section we discuss three above mentioned approaches for generating metadata about learning objects.

2.1 Profile-based Indexation

With profile-based indexation, information about the author/indexer is used to deduce document properties. The general idea is that different documents of one specific author are often quite similar. An obvious example is the institution that the author works for: this information can be inserted automatically, as it does not vary for most documents.

We are investigating how this profile-based approach can be extended to information about the courses the documents are used in. Quite often, a batch of documents is indexed at once within a same course context. Several properties can be assigned to all these documents. At the beginning of the indexation, the appropriate courseprofile can be loaded. As an example, while indexing documents about sorting algorithms for a programming course, we can preserve many of the semantic and pedagogical attributes. The concept of the documents can be 'sorting algorithm' and the didactical context can be 'university first cycle'.

2.2 Document Properties Analysis

Most technical metadata attributes can be derived automatically from the intrinsic document properties. Obvious examples are file size and name, MIME types, and so on. In most operating systems, all documents have associated metadata, such as the file name, permissions for different classes of users, etc. Specific document types have document specific attributes, which provide more detailed information about the document. We can also declare user-defined attributes for the documents (e.g. typical learning time, ...). All these attributes can easily be retrieved and recycled when the document is indexed with Learning Object Metadata.

Many operating systems also support inheritance of document properties through document templates. MS Word and MS PowerPoint documents, for instance, use a document template (.dot or .pot file) for their style definitions. These templates carry metadata (called "properties") also and all the documents based on them inherit those properties. In this manner, we can define a 'course specific' template with the appropriate metadata for attributes like discipline, main concept, didactical context, and so on. All the course documents based on this template inherit these metadata values automatically (see Figure 1). As an example we could have databasecourse.pot and programming.pot file for the slides of two courses, one about databases and another about introduction to programming.
2.3 Similarity Search

A potentially very strong mechanism for automatic indexation is the reuse of existing descriptions when generating metadata for new documents. In the ARIADNE Knowledge Pool System, the indexer can do this manually [Duval et al., 2001], by editing an existing description to create a new one. Automating this process can be based on similarity search. Similarity search is often implemented in web search engines (see for example GoogleScout from http://www.google.com). These search engines compare web sites and classify them according to an ontology (see http://www.dmoz.org about the open directory project). Each line in the result can be used to query for pages related or similar to the page in that line (Figure 2).

Extending this mechanism allows us to find similar learning objects in the repository and automatically reuse their descriptions to create a new one. The indexation tool creates a summary of the document and searches for matching summaries in the databases. The metadata for the best matching document is reused as the basis for the new metadata.

3. An Indexation Framework

The framework we are developing fits in the ARIADNE Knowledge Pool System (KPS) as an automatic Learning Object Metadata indexation tool. It tries to combine the above-mentioned indexing techniques. A first prototype analyses HTML and MS Word documents. For other document types, only evident attributes - mostly technical values - are extracted. The current version of this tool implements the document properties analysis and profile-based indexation; similarity search is not supported yet.

The result of automatic indexation is a LOM XML instance, which can be inserted into the KPS as a new element. The framework allows easy extensions with new document-specific index classes, which handle one type of documents, for example portable document format (PDF) documents.

4. Conclusions

In this paper, we proposed a combination of three techniques for automatic pedagogical metadata generation. We are convinced that (semi)automatic indexation can help knowledge pool systems to gather the critical amount of data to be widely useful and used.

The prototype indexation tool and framework we discussed fits in the ARIADNE Knowledge Pool System. The current version of this tool indexes HTML pages and MS Word documents. It can be extended by new indexer classes.

The third methodology of metadata generation, similarity search, must be studied further. In our opinion, this can be very helpful to generate accurate metadata (semi-)automatically.

Abstract: Considering the take-up of e-learning platforms at Higher Education Institutions (HEI) as an innovation process, it is arguable that HEI have to be themselves re-designed and that innovations promoted at a course level should therefore be articulated within a broader institutional level. This creating conditions for successful re-think the HEI intervention, allowing more flexible operational modes. Focusing in the development of knowledge and understanding about the adoption and use of e-learning systems in HEI, a case study was structured based in an initiative being launched at a traditional university department. Elements of the environmental, organisational and information system context are identified as key influences of the innovation process.

Introduction

Although it is generally accepted that web-based technologies offer valuable opportunities for innovation in education, their generalized integration in higher education activities is considered to be still relatively incipient (Collis & Pals 2000). There is a great interest in the use of these technologies in education but the uptake has been slow and with very few visible changes (Bates 2001). In order to consider the adoption of distributed learning environments (DLE), based in e-learning platforms in high education institutions (HEI) as an innovation process, it is necessary to contemplate in the first place the need of HEI re-structuring from an organizational point of view, so as to fully exploit the new opportunities offered by these learning technologies (Liber 1999). The innovations promoted at course level should be articulated in a wider institutional viewpoint, leading to a reappraisal of the traditional HEI intervention (Taylor 1998), enhancing the development of more flexible models of operation. The implementation of these technologies implies, as a rule, significant changes in both the innovation and organization (Rogers 1995). Focusing on the contextual and processual elements associated with the action of key players, the technology-based organizational change may be represented through the model adapted from Orlikowski’s proposal which points out the interactions between the institutional context and the process of adoption and use of the technology (Orlikowski 1993). Creating conditions for the adoption and use of DLE in HEI can be seen as influenced by the environmental context of HEI operation, from the organizational context and from the DLE specific information system (IS) context. Whereas those conditions themselves will also influence the wider institutional context.

A case study was structured based on an innovation process being launch at the Information Systems Department (DSI) of Minho University - Portugal. Data collection covering the initiation phase of the adoption process included relevant documents, reports, meetings notes, and written communications picked up in the departmental mailing list and other email exchanges. Fourteen DSI leaders and teachers were interviewed following a semi-structured format during 2000/2001. Interviews cover organizational, social, cultural, technological, pedagogical and methodological issues (Fullan 1991). The collected data is being processed using content analysis, which is the main qualitative analysis form applied in this research (Bardin 2000).

Results

From content analysis, the key-concepts associated to institutional change categories (such as environmental, organizational and IS context) which influence the conditions for adopting and use DLE in HEI, were being identified and are presented below (Figure 1).
Shared understanding about the Role of DLE

Technology-based innovation in a HEI organization can be understood as the result of human interaction, as a process where meaning is gradually worked out through discussion, dealing with different arguments and points of view. DLE can be exploited by teachers and by the institution even though with very different goals, implementation speeds and achievements. Building a shared vision and a common understanding of the role technology plays in HEI is certainly a major issue to face. The adoption of a research attitude, along with the design and preparation of demonstration trials proved to be a way to achieve the change desired. Such trials can also contribute to a deeper awareness and understanding of the possible role of e-learning systems. They have allowed DSI to mark "the development of a coherent and mature vision of the use of these products in higher education" and have also facilitated institutional decisions.

Pedagogical Leadership

The discussion concerning the role technologies play in education and HEI development is still very active. This type of innovation will, along with the adoption and use of a new technology in the organization, require a real change in professional practices. With this change happening in the main activity of an organization, even if itself helped to identify and give merit to the decision to innovate, it still is an ambitious goal and a deep change. This is a situation of facing a process of pedagogical re-engineering: course enrichment or redesign (Collis 1997). The competence in defining a policy for the adoption and use of technologies in an uncertain context is a key issue, whether it refers to the evolution of this technology in the market or to more global adoption policies (at a school level, university, national...). In this context, emphasizing the pedagogic change which might be involved, and the notion that the department must possess a distributed learning system turn out to be decisive factors.

Caris@adelphi.edu

Abstract:
At the Faculty Technology Center of Adelphi University, we support and advise faculty in technology-related questions or projects. We offer ongoing workshops on a large variety of topics in educational and instructional technology. The workshop focuses on communicating difficult to explain concepts through a variety of media.

Introduction
Our workshop uses both inductive and deductive pedagogies to build an interactive course/syllabus template for visual learners (Nishikant & Sonwalker, 2001). Induction suggests that learners first be introduced to a concept or a target principle using specific examples that pertain to a broader topic. The examples enable learners to develop their own connections between the concept and the examples that confirm the principle. Recommended content and media objects for induction including text, graphics, audio and video. The other learning style is deductive, which is based on stimulating the discernment of trends through the presentation of data, simulation, graphs, charts or other data.

Faculty today are widely required to include online components in their teaching. Developing learning material is time consuming and challenging. A generic template, for interactive course content elements, can be adjusted for the course goals. The template can be used for both the online setting and face to face settings. We will discuss a general educational template that we designed with Flash. Results and data will be provided on how faculty at Adelphi used such an application.

The workshop for designing visual learning material is our first attempt in taking full advantage of the online medium. We first start with building small multimedia elements to be implemented in a media rich adaptive environment.

Brief overview of the workshop
The workshop described here covers four days (six hours a day). We had three instructors and two student Educational Technologists providing information and assistance. We used a five-part framework of vision, design, production, outcomes and analysis. Participants introduced themselves to each other and conveyed their expectations and their goals.

The first day we covered the theory of visualizing data and basic theories of displaying visually difficult concepts (E. R. Tuve ‘Envisioning information’ Herdeg, ‘Herdegs graphics/diagrams’).

We used induction to expose the participants to Flash and showed examples and explained what might be possible to exploit with Flash.

We employed hands-on activity with the program to demonstrate the basic elements; symbol, timeline, layers. At the end of the day participants suggests learning elements (concepts) they might want to explain using multimedia elements. Discussion with all participants was initiated.

The second day a brief paper design is made. The theory of design, flowcharts and concept mapping is covered. In the afternoon we started with the first principles of Flash and worked out a small assignment (via a template of 3 layers 1 images and 2 objects).

We discussed how effective templates can be. How precisely templates work to explain the abstraction for all type of learners?
The third day, we discussed their storyboards (at least four screens showing the animation, text and images). We talked about some theory for recording sound and shooting video. In addition copyright issues are pointed out.

We wrote instructions to explain the equipment and software. To record sound, we use the computer Sound recorder. Each participant records at least 1 minute of voice and music via the internal CD player. For shooting video, small personal cameras are handed out.

The assignment for video is to give a brief introduction to each participant’s own course they design their visual material for. The assignment is to find a setting and an activity, which demonstrate who or what the person is. Talking heads was discouraged. This gathering of video footage was a collaborative effort; each participant recorded the video of another participant.

At the end of the day in the discussion we talked about the difficulties of recording voice and mixing sound with music, and gathering some good video footage. Producing audio and visual material stimulated ideas about how to present this material in an online class.

Day four started out with participants reflecting on each of the sound and video products. After this general session the participants worked on their animation and brought in sound where needed to support the visual elements. The video clips where treated as 'stand alone' and saved as QuickTime movies.

The animation was saved as a shockwave file for easy delivery via the Internet. All these elements where brought on to a WWW-page and into Blackboard.

These hands on-activities helped communicate the wealth of opportunities for multimedia to enhance the learning experience. The design and development of the combined media components – text, graphic, audio video animation- will eventually depend on the learning model appropriate for the delivery of given course content. This should be covered in a follow up workshop.

Participants feedback
The participants expressed surprise how far they had come in only four days. There was also concern that too much material was covered for that condensed time period.

The workshop has made some faculty aware of breaking up teaching material into smaller units.

The faculty has gained insight into how ‘easy’ it is to use or develop audio and video and animation. They wanted to continue to build more animation as part of the courses.

Participants find using or having a video camera in the classroom a good idea. They saw how helpful footage might be for reflection on teaching and for backing-up lectures and for lab experiences.

Implementation into Blackboard or WWW-pages was relatively easy but not always without problems.

Our reflection
Templates did not really save time or provide better understanding for programming Flash. A format can be designed in which elements can be placed. But this is more limited than a template.

We suggest incentives for faculty to design their own teaching material.

On-line AACE Forums: Joining, Participating, and Leading

Roger Carlsen
Wright State University,
College of Education and Human Services

Attempts to create and sustain on-line professional communities for teacher education have received considerable attention from the press. Frequently, however, on-line groups do not deliver what on-line users want. We can, with reasonable assurance, identify and nurture those factors that increase the likelihood of sustainable on-line learning community success. These factors fall into four general categories. First, the selection of an ease of learning and ease of use application permits an adequate default setting to begin operation yet permits users and managers to customize their on-line environment. Second, creation and support of users, moderators, and administrators by providing training and supporting excellent experiences that evolve into an on-line learning culture. Third, both users and managers must believe that content of an on-line group is an added value. Fourth, the effort required to participate in an on-line professional group are worth the added effort.

Most educators will admit that the current state of online groups are not as good as they will become (Vail, 2001) and perhaps view on-line groups as another e-mail like media to be managed (Barmann, personal communication, February, 1993). This perspective is due to educators attempting to fit technology into the traditional world without recognizing how on-line interactions can change and add value to lives. In the professional literature one rarely reads that deeper and different learning can happen in an on-line learning community, but it can.

Educators more commonly read about and subscribe to the popular idea that face to face interactions in a traditional room are the ideal. In traditional interactions the presenter speaks to the audience. At a conference there is limited interaction and contact over a relatively short time. The use of AACE and SITE professional boards permit and encourage more extensive and longer lasting connections.

Personal interactions involved in face to face learning can be powerful. We must also recognize that an on-line community of collaborating peers where every person sees, discusses, and reacts to thoughts and ideas of individuals within a group can be extremely
accommodating related to content, as well as time and distance. Participation in on-line professional groups and a skillful use of technology creates more than just a difference in the way we work. It will provide an ubiquitous on-line learning vehicle, a place to express and develop ideas, and provides us with access to a support group of our peers. Such a community is exceedingly powerful. An on-line learning community can add muscle and flexibility to the learning experience. An on-line learning community has the potential to add value to the learning enterprise.

In a recent welcoming address to MIMIC, the Dean of Cleveland State University, Dr. James McLaughlin said it exactly right when he said:

"Technology has become such an integral part of my life that I wonder how I did without it. I knew that it would allow me to do my work differently. What I did not realize was how it would change my thought processes, professional identity, and communication frequency and style....

I think differently too. Having information at my fingertips allows me to rely on my memory for other things. I scan for the immediately relevant and otherwise store information away for quick retrieval. I am more prone to think ahead than behind. I seem more adventurous than before."

Delivered MAY 20,2002
Dr. James McLaughlin, Dean
College of Education
Cleveland State University

Most educators still use technology tangentially as an add-on and are not motivated to use professional on-line groups in their professional lives. They too often continue to perceive the use of technology negatively and an effort without adequate incentives or tangible rewards (Schlager, Fusco, and Schank, 1998). The majority of teacher education faculty still fails to infuse educational technology procedures into their educational curriculum at substantial levels.

The point is that, other than using the web for cheap access to free materials, teacher educators seemingly do not recognize that on-line participation in a professional group is beneficial In many instances, web-based groups and listservs are led by those who have failed to experience sufficient on-line activities to enable them to plan or lead on-line groups. Sometimes there is a failure to continue to maintain the on-line activities once
they were launched. Think about this, how often is webpage content out of date? We believe that when faculty have had few or no positive experiences creating and leading an on-line learning community, they seem to retreat toward teaching the way they were taught, that is, without technology (Schlager, Fusco, Schank, 1999).

Whether one is an on-line learning community user or leader, success requires the use of an application that is robust and flexible. At AACE and SITE we use software that:

- is easy for all users to learn
- is easy for moderators to learn and manage
- is dependable and requires little maintenance and is secure
- can attach files created with most popular applications
- offers a variety of personalized settings

Examples of personal configuration options include, notification of the creation of new discussion topics being formed in one’s favorite areas, subscription to topic threads, hiding topics and conversation areas where one has little interest, and much more.

Many universities use campus-wide software such as WebCT® or WebBoard® as their solution for web-based content. Both of these applications are excellent. This presentation will reference these applications so that users who are familiar with them can understand functionality of AACE’s professional boards.

Initially participants may view on-line groups as being unsatisfying and as an isolated activity. This need not be so. The promise of anywhere, anytime connectivity is becoming a reality. When educators are uninitiated into an on-line culture or they have inadequate training and support the tendency is to retreat from the on-line leadership position. Content flows into AACE and SITE forums participants begin to support each other. Everyone is able to see how others think. This brings up an important point to remember, participation in an on-line professional group is not like sending e-mail. Thoughts should be well crafted and often demand thoughtful reading and pithy (responses requiring deliberation, not just yes or no) replies.

The AACE and SITE professional boards represent an agora, what we would call a forum for open discussions. Agora is an ancient Greek term for an open space where citizens come together for public meetings. An agora was first attributed to Homer and connoted
both a) the assembly of the people or congregation and 2) the actual physical setting. An agora, much the same as what we would think of as a “commons” was regarded as an ordinary element of their life. Every citizen had a voice. These are similar to the learning communities that AACE and SITE are developing on-line.

On-line learning communities will evolve. One must be careful, however, because there are assassins waiting to kill the on-line learning community. Apathy and non-participation is a dangerous thing. When teachers and administrators fail to gradually acquire on-line management knowledge and skills they limit their ability to understand and develop on-line learning communities. When one uses technology one improves speed and range of collaboration and communication. The use of on-line communication applications also exposes charlatans. Cultural readiness may trump some efforts to form on-line learning communities. In the past we have waited 20 years for a new generation of educational leaders. Today we can not wait. We must work to build the educational culture that will support and value on-line knowledge sharing.

When Thomas Carroll (2000) asked the question, “If we didn’t have the schools we have today, would we create the schools we have today” he was really asking us to make something different. An electronic on-line learning community is not business as usual. On-line learning communities permit us to share half thoughts and enlist others in their development. It permits others in on the secret and the private information, and makes the whole process more democratic, in part because I can access so many people so easily (McLaughlin, 2002).

Activating Web-Based Learning

Randal D. Carlson, rcarlson@gasou.edu
Georgia Southern University, USA

Judi Repman, jrepman@gasou.edu
Georgia Southern University, USA

Abstract: Students today expect learning to be linked to the real world and by using active learning strategies we can help students develop those links. Active web-based learning involves the user being engaged in a knowledge-building, skill-building, or attitude-changing task, and being required to meaningfully and overtly interact with instructional content. This brief paper explores the idea of active learning on the web and examines some good examples of web resources that incorporate basic principles of active learning.

Active Learning

The test of a good teacher ... is, “Do you regard ‘learning’ as a noun or a verb?” If as a noun, as a thing to be possessed and passed along, then you present your truths, neatly packaged to your students. But if you see “learning” as a verb[,] the process is different. The good teacher has learning, but tries to instill in students the desire to learn, and demonstrates the ways one goes about “learning” (Schorske, cited in McCleery 1986, p. 106).

Schorske invokes the argument that “good” teachers use active, not passive, processes to encourage learning. This brief paper explores the idea of active learning on the web and examines some good examples of web resources that incorporate basic principles of active learning.

Many, if not most, faculty members have an intuitive understanding of the term “active learning,” but have difficulty defining it. This leads to general agreement over the need for active learning, but ambiguity and confusion over how to make this part of our instruction. For most of us, active learning means learner involvement with both the instructional content and learning processes. Logically, this implies that any type of interaction between the learner and the instructional content indicates active learning. Yet traditionalists choose “passive” activities such as listening to deliver instructional content, asserting that test grades “prove” that learning has taken place. Students can learn from teachers who use passive strategies — they have been doing so for years. Listening to lectures is probably the way most of us spent the majority of our time as students in various classrooms. How can we respond to this argument?

Learning strategies form a continuum from passive through active. While each endpoint is useful and has value in different situations, we also agree with Bonwell and Eison (1991) that in active learning

- Information transfer is less important than skill building,
- Higher-order thinking skills (problem solving, cognitive strategies) are emphasized,
- Students pursue activities that involve doing something more than listening, and
- Students’ exploration of their own attitudes and values are emphasized.

Examples Of Web-Based Active Learning Sites

It should be an easy task to find numerous examples of active learning sites on the web. However, it is difficult to find truly interactive, learning sites. Our operational definition for active web-based learning is that the user has to be engaged in

- a knowledge-building, skill-building, or attitude-changing task, and
- during the usual course of the task the learner must be required to meaningfully and overtly interact with instructional content.
We also consider the core techniques Silberman suggests: team-building, on-the-spot assessment and immediate learning involvement. (1996, p. xi)

A look at the web revealed many excellent learning aids, but few active learning sites. Most of the sites that we classified as useful for instruction came in the form of web-based books. These sites were usually colorful, content-rich, interesting, well organized, and focused, but lacked any feature that would require the learner to interact with the content short of clicking “next” or choosing from a pull-down menu. Another common site layout was a question bank or test on a particular subject area. The third type of site that we found was one that promised to be useful and. Unfortunately, many of the truly interactive sites were fee based. Some had part of their content available (and we used some of these sites as examples) so we could see the added value of the active instruction. What follows is a compendium of sites that exemplify active learning principles.

Sprocketworks (http://www.sprocketworks.com/) showcases games and other instructional resources designed with Shockwave. Categories include space, music, U.S. history, flight, horses, chemistry, birds, ships and oceans. While some of the games are strictly knowledge level (ocean trivia, for example) others do build problem-solving skills in a creative an interactive way.

A. Pintura: Art Detective (http://www.eduweb.com/pintura/) is an online game about art history and art composition designed for fourth grade and up. In the game, you play a 1940’s noir detective with a degree in art history. In it, a distraught woman asks you to identify the artist who made a painting she found in her grandfather’s attic. To do so, you must examine paintings by famous artists from Gauguin to Van Gogh. Each example highlights an art concept such as composition, style or subject.

Learn Spanish (http://www.studyspanish.com/) is a site designed to complement an audio CD series. This free online tutorial currently covers over 50 separate topics, including written and oral exercises and an automatic, free grading service. Also available is a vocabulary builder with interactive games, Cultural Notes for Spanish-speaking countries, a text and web translator, and other interesting and useful features.

Visual Calculus (http://archives.math.utk.edu/visual.calculus/) is a collection of tutorial modules that can be used to review or teach calculus. Examples abound in this NAWEB 99 winner in the single course category. NAWEB annually honors outstanding achievement in the field of web-based instruction. One of the problems associated with this site is the requirement to have a specific (and quirky) plug-in loaded. It may not be for everybody.

Biology Labs On-Line (http://vcourseware.sonoma.edu/) is a series of twelve (12) different inquiry-based, interactive labs designed for college and AP high school students. This is a diverse collection of labs that cover many different subjects in the biology field. All of these labs are subscription based. A free 3day trial subscription is available.

Who Killed William Robinson? Race, Justice and Settling the Land (http://web.uvic.ca/history-robinson/indexmsn.html) is an invitation to students to solve an 1868 murder by examining the archival records relating to the death of William Robinson, a Black American murdered in the British Colony of British Columbia. In seeking the real murderer site-users will come to terms with racism, (in)justice and patterns of land settlement in the colonial world.

Conclusion

The web is a great resource. It is simple to present information to students. But, learning involves more than just the presentation of information to students – it involves the student interacting with the information in such a way that the information becomes a part of his knowledge structure. As teachers, we are charged with the responsibility with designing and developing these knowledge systems – systems that encourage active participation of the student. The preceding examples provide models of good, web-based active learning sites.

Introduction to Educational Computer Technology: Evaluating a first phase of a Distance Learning Program in Brazil

The Government of Rio de Janeiro, through the Secretariat of Science and Technology -SECT- created the Center of Distance Learning of Rio de Janeiro – CEDERJ, coordinated by the SECT. The CEDERJ is a consortium of the six public universities of Rio de Janeiro (UERJ, UNIRIO, UENF, UFRJ, UFF e UFRRJ). The aims of CEDERJ are: (a) to contribute to the spread of public higher education among municipalities in the interior of the state of Rio de Janeiro; (b) to foment the access to higher education of those that cannot study in the traditional schedules; (c) to act on continuing education programs, with special attention to teachers of the public education schools using distance learning mode; and (d) to increase the offer of vacancies in undergraduate and masters courses in the State. There is a technical and pedagogical staff that is in charge of elaborating different support material for the web, printing, and video. This staff is also responsible for the evaluation process.

A homepage (www.educacaopublica.rj.gov.br) elaborated and maintained by our team is a place for teachers to get information about courses and workshops, to play author role writing articles, relating their experience and interact with other teachers to discuss teaching and learning processes.

Regarding one of the CEDERJ aims, to offer teacher professional development courses and workshops, we will present an analysis of one educational computer technology course. The purpose is to evaluate aspects such as interactivity, student autonomy, and student cooperative work in a program based on a constructivist approach. Participants were 23 teachers from different subjects, teaching in public middle and high schools in Niterói, Rio de Janeiro. The teachers/professors who implemented this course were members of the CEDERJ staff. They planned the course and all resource material to be used.

The Course

The course was developed by a multidisciplinary team: educators, designers, programmers, illustrators and editors. The lessons dealt with hands-on activities to develop basic computer skills. For many of the participant teachers, the face-to-face phase, focus of this paper, was a unique opportunity for handling a computer. The topics discussed included the Windows environment, using the Internet, registering an e-mail account, using a text editor, and participating in educational chats and forum. To better achieve our goals, instead of just telling the teacher/students what to do, all the tasks were always initiated with a challenging question and not with an explanation. It was a 20 hour-course, divided in five meetings.

The Didactic Material

The didactic material included: material to be used by teachers or future tutors, printed material for participants and a CD-Rom with programs and a navigation simulator to be used in the computers if any problem emerged with the machines during the meetings.

Teachers in (inter) action

The participants worked in pairs, attending Vygotsky’s theory about knowledge production. They registered their findings, suggestions and critiques in a daily log, written at the end of a meeting using the WordPad. The advantage of using a collaborative/cooperative learning approach is to promote a reflection not only upon an individual work but also on the group production. Students come to view their peers not as competitors but as resources. Mutual tutoring, a sense of shared progress and shared goals, and a feeling of teamwork are the natural outcomes of cooperative problem-solving, and these processes have been shown to produce substantial advances in learning. The teacher served as a guide, rather than the source of knowledge. The teacher was there to organize and to assist the participants while they take the initiative of their self-directed explorations, instead of directing their learning autocratically. Flexibility was the most important feature of teacher’s role in such environment. Sharing their findings allows teachers and participants to reflect upon their actions and to recognize all contributions as valid ones. It was important to reassure their self-confidence and moreover to develop a new attitude.

Evaluating this course

Our goal was to evaluate this course, to do so it was important to find a model that helped us to identify indicators to be used in future evaluations. We found out that the conflict between quantitative and qualitative analysis relies more on the nature of the goals than in a natural cause.
A particular method, illuminative evaluation, is now being widely used in the U.K. for evaluating human-computer interaction and computer-assisted learning. Illuminative evaluation approach, first outlined by Parlett and Hamilton, addressed the question of using scientific quantitative approaches to educational evaluation without regarding specificities of each research field. Our investigation matches the suggestions of Parlett and Hamilton (1972) to embrace a more qualitative approach.

"... to study the innovatory programme: how it operates; how it is influenced by the various school situations in which it is applied; what those most directly concerned regard as its advantages and disadvantages; and how students' intellectual tasks and academic experiences are most affected. It aims to discover and document what it is like to be participating in the scheme, whether as teacher or pupil; and, in addition, to discern and discuss the innovation's most significant features, recurring concomitants and critical processes. In short it seeks to illuminate a complex array of questions: ..."

Observation was one of the main methods of collecting data and was especially useful during the early 'immersion' period. The teachers/investigators and researches built up a continuous record of events that were considered important for this study taking care to not underestimate events that could also bring lights to this study. Discussions between participants are recorded, and great attention was on language conventions, slang, jargon, and metaphors that characterize conversations, as well as in written materials as logs or e-mail messages. It revealed tacit assumptions, interpersonal relationships and status differentials. Also, we were very careful while analyzing data in order to triangulate or cross check data analysis.

Evaluation and analysis were done in a daily basis as mentioned before. After the 20 hour course we had collected data from participants log and e-mail messages, and we needed to categorize the indicators in order to organize them according to their nature. We will present and discuss each of the indicators: (1) cooperative work; (2) autonomy; (3) viability of the course; and (4) Interaction.

In summary, teachers acted as participant observers and appraisers immersed in the context with two specific purposes: to better understand different aspects of course impact; and then to extract considered tracks for future change or continuance of the program course. The procedure steps were: (a) All the impact indicators were registered (b) Impact evidences were selected, then (c) Final analysis was undertaken and generated a discussion study group that is still in the process of planning future courses.

Analysis and Partial Outcomes - Regarding the course content and pedagogy
The group chosen for this study was quite heterogeneous and some of the participants had attended other courses. Eighteen of them had computers at home, three of those used computer a few times to type a text; only six considered themselves as not so regular users; and the others had never used a personal computer before beginning this course. They were quite unanimous when expressed their impressions of the first meeting, in their words "it is a first time I have the experience of learning the basics".

Participants who had difficulties handling the mouse in the first days were encouraged to play solitaire or free cell before class started. And by the end of the week they were so skilled in using a mouse, they almost forgot their initial difficulties. Finally they were comfortable with that new technology and above all thinking about using it pedagogically in their daily routine.

Looking forward
It is fundamental in planning educational computer technology courses to think about partnership instead of the traditional mode. When participants are not treated as empty vases but as authors of their learning and knowledge production they feel confident in establishing goals for significant changes in their praxis.

This evaluation revealed that regarding our country peculiarities it is necessary to have a face-to-face phase before a Distance Education course. To refer to one crucial point, most of the in-service teachers were not exposed to any computer technology in their undergraduate education and as we mentioned before even those who have, now a day, a personal computer do not know how to use it. Therefore it was and still is important to demystify the use of those machines in a course that helps participants to develop autonomy, self-confidence and consequently desire to continue learning.

Abstract: Although the potential exists to transform higher education through the impact of technology founded on pedagogy, many attempts have met with mixed success because of the fundamental premise that academics have to be intimately involved with the selection and control of their course. The “control issue” argument that is being presented here is that the key to successful integration of digital technologies into the curriculum is by empowering the academics themselves rather than provide some turnkey development service. This paper describes the challenges faced in Trinity College Dublin, a research-led institution and highlights the experience over three years of target initiatives in a research-led university.

Introduction

Many universities worldwide have a reputation based on research excellence, publications and research achievements. In addition to research, teaching and learning are seen to be vitally important. Now there is a powerful new force entering the picture, namely digital technology. Technology is impacting higher education, stirring up debate, and is beginning to restructure the learning-scape. Today higher education finds itself in the midst of an increasingly globally market-driven new economy, along with rapid social transformations while dealing with the impact of technologies. Given changing student demographics, rising costs, overcrowding, faculty shortages, increased accountability, and other external factors, universities are re-examining their long-standing values and practices in order to find ways in which to meet these challenges successfully (Van Dusen, 1997). The debate over digital technologies and meeting these challenges, is causing a paradigm shift by moving higher education away from an educator-centric environment toward a more learner-centric educational environment presenting even further challenges to educators in acquiring the necessary skills and competencies related to technology and pedagogy. In the not too distant future, institutions that are integrating technology successfully to improve teaching and learning, as well as research will be seen as more dynamic and effective than their less-engaged competitors (Newman & Scurry, 2001).

Strategies for E-learning Integration

Cultural change is required for colleges and universities to be successful in harnessing the power of digital technologies in ways that capitalize on what we know about how students learn, that
they learn more when they are actively engaged in self-driven rather than passive learning activities (Newman & Scurry 2001 & Lim, 2001). One can consider cultural change at three levels, academic, organisational structure, and external influences. When developing policies and solutions these levels need to have representation across college.

We believe that one of the first places to start is at the academic level. Some of the key factors for instigating change at this level include: identifying early adopters, increasing awareness; providing professional development and incentives (e.g. monetary, time off, recognition); emphasizing pedagogy over technology; ensuring technical support and sustaining this cultural change. Secondly, cultural change is dependent upon the organizational structure. Goals of the university must include harnessing the power of technology to improve teaching and learning. The organization must support this by restructuring to some extent if necessary. Integrating with existing college services is critical. A combined top-down and bottom-up approach is essential. Thirdly external influences must be considered such as the shift from local markets toward a global economy; an increase in the demand for quality assessment; and the growing and changing role the government in higher education.

Case Study

At Trinity College Dublin (TCD), the University Council and Board established the Centre for Learning Technology as a joint initiative involving College Academics, Staff Development Office and Information Systems Services which is responsible for supporting academic staff instigating & developing innovations in teaching and learning with Information and Communication Technology. The Centre's objectives are to support e-learning across College by: supporting numerous (six monthly) e-learning projects in all departments; providing consultancy services for e-learning initiatives in TCD courses; and hosting seminars, workshops and courses in e-learning pedagogy & technical skills. One major lesson learned from the Centre’s successful initiatives is that a holistic, pedagogically led approach to enhancing learning with digital technologies is required and that it is essential to integrate it within the university’s academic community and organisational infrastructure.

Some successful strategies for providing support identified here at Trinity College Dublin over the past three years include: integrating services; emphasizing pedagogy over technology; identifying early adopters; providing high quality professional development and incentives (e.g. monetary or time off); increasing awareness in incorporating research for publication; facilitating knowledge building and sharing; ensuring recognition and support by college body; and providing technical/pedagogical support.

NASA Langley/CNU Distance Learning Programs

Randall Caton, Christopher Newport University, 1 University Place, Newport News, VA 23606

Thomas E. Pinelli, Office of Education, NASA Langley Research Center, 17 Langley Blvd., Mail Stop 400, Hampton, VA 23681

I. Introduction

NASA Langley Research Center and Christopher Newport University (CNU) provide, free to the public, distance learning programs that focus on math, science, and/or technology over a spectrum of education levels from K-adult. The effort started in 1997, and we currently have a suite of five distance-learning programs. We have around 450,000 registered educators and 12.5 million registered students in 60 countries. Partners and affiliates include the American Institute of Aeronautics and Astronautics (AIAA), the Aerospace Education Coordinating Committee (AECC), the Alliance for Community Media, the National Educational Telecommunications Association, Public Broadcasting System (PBS) affiliates, the NASA Learning Technologies Channel, the National Council of Teachers of Mathematics (NCTM), the Council of the Great City Schools, Hampton City Public Schools, Sea World Adventure Parks, Busch Gardens, ePALS.com, and Riverdeep.

II. Major Goals of Distance Learning Programs

Our mission is based on the “Horizon of Learning,” a vision for inspiring learning across a continuum of educational experiences. The programs form a continuum of educational experiences for elementary youth through adult learners. The strategic plan for the programs will evolve to reflect evolving national educational needs, changes within NASA, and emerging system initiatives. Plans for each program component include goals, objectives, learning outcomes, and rely on sound business models.

It is well documented that if technology is used properly it can be a powerful partner in education [1]. Our programs employ both advances in information technology and in effective pedagogy to produce a broad range of materials to complement and enhance other educational efforts. Collectively, the goals of the five programs are to increase educational excellence; enhance and enrich the teaching of mathematics, science, and technology; increase scientific and technological literacy; and communicate the results of NASA discovery, exploration, innovation and research.

All pre-college distance learning programs support the national mathematics, science, and technology standards; support K-12 systemic change; involve educators in their development, implementation, and evaluation; and are based on alliances and partnerships.

In addition the programs seek to invoke a sense of geographic, ethnic and cultural diversity by featuring schools from all over the U.S.; schools from urban, suburban, and rural areas; public, private, and religious schools; and schools with large populations of African-American, Asian and Hispanic students.

III. History of Distance Learning Programs

IV. Description and Methodology for Distance Learning Programs

We define distance learning as “getting people—and often video images of people—into the same electronic space so they can help one another learn,” and we provide “a system and process that connects learners with distributed sources”[2]. All the programs are appropriate for one or more of the following national audiences: public, private and parochial schools; home schoolers; girls and boys clubs, colleges and universities, parents, teachers, caregivers, and adult learners.

In this section we discuss the methodologies used to create the various distance learning programs. The broadcast components air nationally on PBS stations and on many Cable Access Channels, but are also available on tape, DVD, and the web.
A. NASA KSNN

**Goal:** Support national efforts to prepare all children to succeed in mathematics, science, and technology.

**Description:** NASA's KSNN is a series of 1-minute news breaks and associated web support and activities that uses children to explain to people of all ages specific mathematics, science, technology, and computer science concepts that often address misconceptions. Confronting misconceptions at an early age with the combination of lively, kid-oriented newsbreaks and activities will fit well into the grade 3-5 classrooms. The newsbreaks will get wide visibility as interstitials on Public Television and commercial networks. See the web site at [ksnn.larc.nasa.gov](http://ksnn.larc.nasa.gov) for more information.

**Methodology:** We have a pilot program in place at CNU to develop scripts, activities, and web page content for NASA KSNN. Teams of 3-4 students develop scripts, activities, background material and web page content for one of NASA's KSNN newsbreaks as part of their course work and the teams find a content expert for their project at CNU, NASA, Jefferson Lab, or another appropriate institution. Effective communication with 3-5 graders through the video medium is presented in class; students present their newsbreak for video taping and report on the other components. Finally, a committee of CNU and NASA judges selects the best projects each semester for production. Involving pre-service teachers is valuable for their education and introduces them to NASA distance learning programs that they can use in their classrooms.

**Student Outcomes:** 1) Stimulate interest in and increase understanding of mathematics, science, and technology; 2) correct commonly held mathematics, science, and technology misconceptions; 3) gain awareness of NASA: programs, projects, and facilities; 4) increase scientific and information technology literacy; 5) increase interest of minority and female students in mathematics, science, technology, and NASA; and 6) improve literacy of students who do not use English as their primary language.

B. NASA Science Files (formerly NASA Why? Files)

**Goal:** The NASA Science Files television broadcast, web site, and educators' guide use Problem-Based Learning (PBL) to help students in grades 3-5 explore topics through scientific inquiry.

**Description:** This program consists of a series of four, standards-based instructional programs for grades 3-5 that introduce students to science as inquiry, the scientific method, problem-based learning and NASA. Each 60-minute program is divided into four 15-minute “teachable segments” and is supported by a web site and resource-rich teacher guide. See the web site at [scifiles.larc.nasa.gov](http://scifiles.larc.nasa.gov) for more information.

**Methodology:** In the television broadcast, the tree house detectives are confronted with real-world problems and are provided with the knowledge and tools to attack the problem. The tree house detectives walk through the problem solving process during the four 15-minute instructional segments, reaching a solution in the final segment. The television broadcast features content experts from NASA and the community with careers requiring problem-solving skills, museum resources, experiments, and classroom activities to help the tree house detectives solve the problem. The web component of the NASA Science Files is the nerve center of the learning experience and contains separate sections for students, educators, and parents. The kids' tree house contains content information, experiments and activities, experts to contact, and a variety of other resources to aid student teams in finding possible solutions to the featured online problem. The design of the site encourages the teams to take on roles and approach solving the online problem as a scientist would. An array of Problem-Based Learning tools (action plan, basic design log, PBL questions, “get up and go”, problem board, problem log, reflection journal, scientific investigation log, scientific method flowchart, scientific process log, and web site evaluation) is readily available for them to employ as they research the problem. The web site provides resources and guidance for the team's culminating report and presentation. The educators' area of the site is structured so that essential information is one click away and other information a maximum of three clicks away. It contains an overview of the NASA Science Files television broadcast, web site, and educators' guide and is an excellent starting point for professional development in the area of PBL. PBL instructional tools and strategies, worksheets, classroom activities, and assessment tools can also be found on the site. The educators' guide is designed to augment the television broadcast and can be downloaded from the web site or received in the mail. The guide features segment overviews, program objectives, vocabulary, classroom activities, worksheets, literature and Internet resources, and implementation strategies. A team of elementary school teachers, NASA researchers, and NASA Distance Learning Center staff develops the programs and guides.

**Student Outcomes:** 1) Increase understanding of Problem-Based Learning and science as inquiry; 2) develop the literacy and technology skills needed to use the Internet for investigation and research; 3) increase scientific and technological literacy; 4) gain awareness of careers requiring problem-solving skills, mathematics and science proficiency, and technology application; 5) view mathematics, science, and technology as a process requiring creativity, critical thinking, and problem-solving skills; 6) gain awareness of NASA: programs, projects, and facilities; and 7) overcome stereotyped beliefs by learning about women and minorities actively involved in challenging engineering and scientific tasks.
C. NASA CONNECT
Goal: Support the integration of mathematics, science, and technology in grades 6-8.
Description: NASA CONNECT establishes the “connection” between the mathematics, science, and technology concepts taught in the classroom and NASA research. Each program consists of a 30 minute broadcast (also available on video tape), a classroom activity, and a web activity, which are supported by a web site and resource-rich teacher guide. See the web site at connect.larc.nasa.gov and published articles [3,4] for more information.
Methodology: The three components complement one another and produce a cohesive, flexible unit for classroom use. The broadcast intersperses classes of students from diverse backgrounds and geographical locations doing the classroom and web activities with NASA experts from diverse backgrounds who describe their research and use of mathematics. Two dynamic hosts weave the story together and take the students on an adventure in learning. Throughout the video, the cartoon character Norbert invites the viewers to pause and consider questions on what they are learning. Short animated mathematics activities are featured during the video as reinforcement. The script for the video is produced in conjunction with educators and the scientists featured in the video to be an effective learning experience for middle school students. The activities are developed and tested by educators who provide an overview, connections to national standards, resources, a glossary, a complete description of the activity, and extensions and questions. In practice a teacher would ideally first use the video with the class, next do the classroom activity, and finally act as a facilitator for the web activity. However, teachers often don’t have the time for all three components so they are designed as independent units.
Student Outcomes: 1) Make connections between the mathematics, science, and technology taught in their classroom and the real world applications by observing NASA engineers and scientists; 2) increase understanding of mathematics, science, and technology concepts through hands-on and interactive web activities; 3) develop the literacy and technology skills needed to use the Internet for investigation and research; 4) view mathematics, science, and technology as a process requiring creativity, critical thinking, and problem-solving skills; 5) gain awareness of careers requiring problem-solving skills, mathematics and science proficiency, and technology application; 6) gain awareness of NASA: programs, projects, and facilities; and 7) overcome stereotyped beliefs by learning about women and minorities actively involved in challenging engineering and scientific tasks.

D. NASA LIVE
Goal: Increase the understanding of mathematics, science, technology, and NASA among: K-12 students and educators, 13-18 students and faculty, and adult (life long) learners in formal and informal settings.
Description: NASA LIVE consists of a series of synchronous (two-way), interactive videoconferencing sessions designed to communicate NASA Langley research, educational programs and career opportunities to educators and students in grades K-12, grades 13-18, and adult learners. A 30 topic series is currently available on the NASA LIVE web site at live.larc.nasa.gov.
Methodology: The programs address the educational need to connect students to real problems and real world applications of mathematics, science, engineering and technology (MSET). Therefore, program topics are chosen based on an educational need to complement university courses relating to MSET as well as aeronautics. After completing the online registration and confirming the presentation date and time, participants (i.e., a NASA researcher with faculty and students) are engaged in an interactive videoconference live from NASA Langley. Each videoconference consists of a 60-minute session divided into a 30-minute presentation, a 20-minute Q&A segment, and a 10-minute overview of educational and professional opportunities.
Outcomes: 1) Stimulate and increase scientific and technological inquiry and literacy; 2) enhance, enrich, and facilitate the learning process; 3) model the effective use and integration of instructional technology; 4) raise awareness of NASA pre-college, college/university, and distance learning programs; 5) gain awareness of NASA: programs, projects, and facilities; 6) increase NASA and university collaboration; 7) increase outreach to the informal education community; 8) increase interest of under-represented groups in mathematics, science, technology, and NASA; 9) improve literacy of students who do not use English as their primary language.

E. NASA's Destination Tomorrow
Goal: Create and heighten the interest of high school students and adult learners in mathematics, science, technology, and NASA.
Description: Destination Tomorrow is a series of five 30-minute nationally aired video programs designed to increase the scientific literacy of educators, parents and lifelong learners. The material is drawn from current research and spin-offs developed at NASA Centers—primarily the NASA Langley Research Center. See the web site at destination.larc.nasa.gov for more information.
Methodology: Research, theory and principles of adult learning guide the developers. Topics are chosen to broaden the public’s perception of NASA beyond space and flight by discussing less known spin-offs of NASA researchers. The 30-minute show is divided into five 5-minute segments: Behind the Scenes, How It Works, On the Runway, Future/Tech Watch, and Retrospective and two 30-second “Did You Know?” vignettes. Two hosts set the tone of the show and introduce the segments. Individual correspondents cover the segments in depth and interview one or two researchers.

Outcomes: 1) Stimulate and increase scientific and technological inquiry and literacy; 2) enhance, enrich, and facilitate the learning process; 3) gain awareness of NASA: programs, projects, and facilities; 4) interest NASA and university collaboration; 5) increase outreach to the informal education community; 6) increase interest of under-represented groups in mathematics, science, technology, and NASA; 7) improve literacy of students who do not use English as their primary language.

V. Validation and Evaluation of Distance Learning Programs

A. Testing and Evaluation of Activities and Web Site

All NASA CONNECT activities are tested by teachers during a special summer program and during the school year in nearby school systems. During the academic year, focus groups of middle school teachers select three NASA CONNECT programs. The teacher and students are observed by NASA distance learning educators as the teachers use the three program components with their students. The observations, informal discussions, and final evaluation report from the teachers serve as tools to continually improve the program. Activities from other NASA centers are tested by the providers. As part of the NASA Science Files web site development, formative evaluation and usability tests are conducted before and during each season with the help of public and home-based educators in grades 3-5. The results are evaluated and used to improve the usability and structure of the web site. Testing in the development cycle is essential to ensure a quality product.

B. Analysis of Survey Data

NASA CONNECT has been evaluated by surveys sent to registrants for three years and NASA Science Files for one year. Although the original questions have been included each year, new questions have been added to improve the survey. For the NASA CONNECT 1999-2000 season [5], 1000 registrants were selected randomly and 27% of the responses were usable (out of a 34% response rate). A total of 99 questions in 9 categories were asked regarding instructional technology and programming in the classroom. Generally, the respondents agreed that instructional technology has a positive impact on learning, is supported by the administration, and that facilities are available for its use. In particular, they strongly supported web-based activities and would like to see more NASA web activities. The assessment of the NASA CONNECT programs was very positive, with overall ratings ranging from 4.17 to 4.63 on a 5-point Likert scale (compared to 4.09 to 4.61 for the 1998-1999 season [6] and 3.97 to 4.56 for the 2000-2001 season). The videos, lesson guides, classroom activities, web activities, and web site were all very highly rated. The use of the videos ranged from 19% to 44%, lesson guides from 22% to 50%, classroom activities from 18% to 42%, and web activities from 9% to 13%. The low use of NASA web activities is in contradiction with the high ratings for positive impact on learning, availability of technology, and desire for more web activities. The low usage may simply reflect that the web activities are the last in the chain of the NASA CONNECT learning offerings (video, classroom activity, web activity). Further, the three lowest ratings for the NASA web activities were: content easily integrated into curriculum (4.09), able to complete in reasonable time (3.86), and appropriate for my students (4.04). Survey data for NASA Science Files for 2000-2001 have overall ratings from 4.39 to 4.64. Both programs have been given consistently high ratings for their program offerings.

Continental Research Associates (Norfolk, VA) conducted an evaluation of NASA’s Destination Tomorrow. The methodology included telephone interviews with 400 (out of 537) managers of cable access television stations across the United States that aired the programs in the 2000-2001 season. Overall, the findings were extremely positive. Significant among the findings were (1) 73.5% of the station managers said that the quality of the programs in the series is "better than average" when compared to other educational programs in their stations; (2) 90.5% indicated the five programs in the 2000-2001 series have been successful in educating people about what NASA Langley does; (3) 64.8% of the stations airing NASA’s Destination Tomorrow reported that the programs have been "very well received" by their audience; and (4) about 80% of those television station managers interviewed stated that the information provided by NASA Langley in the five programs is "very credible."
VI. Future Directions

NASA’s KSNN is in its first season and the one-minute newsbreaks appear to be on target for programming demand in the grade 3-5 category. Spanish versions of NASA’s KSNN programs and web site are complete for the first year and 12 more are planned. Once we have had experience developing the content, we will open up the newsbreaks and web content to a statewide competition. NASA Science Files had a very successful first two seasons and the web page will continue to evolve into a more useful learning center. NASA CONNECT is the most mature of the programs and will continue its present course using the survey results to improve the programs. We are currently streaming some of the video broadcasts from our web site. In the future a complete year’s programs (video broadcasts, lesson plans, and web activities) will be collected on one DVD for dissemination. NASA LIVE is in its infancy but promises to be a very useful program for on-demand video conferencing and has already progressed towards including the K-12 audience in the future. The current mode of video conferencing is directly through ISDN connections. In the future we plan to move to web conferencing and increase the number of available topics. Faculty and students will assess the quality of the content, web-based materials, method of delivery, and the presenter by using an online evaluation. NASA’s Destination Tomorrow also had a very successful first season and will continue along the same lines to produce quality programs that we plan to market to commercial TV. The 5-minute segments are available in Spanish and on DVD. For all the programs, we will continue to promote dissemination and use of the many learning opportunities for all ages. It is clear that it is important to train teachers in the use of our technology-based activities in general and to promote the use of our web activities. We plan to address the need for training in using technology because of the concern expressed in the educational community [7,8]. We will develop web-based training, including technology training for teachers so that they can use our program’s components effectively in the classroom.

The Evolving Electronic Classroom

Robert Cavenagh,
Director of Instructional Technology
Dickinson College, Carlisle PA, USA
cavenagh@dickinson.edu
http://www.dickinson.edu/~cavenagh

Abstract: Electronic Classrooms have become increasingly common over the past decade. The combination of data projectors, computers, video playback, and a range of ancillary devices have been found useful in a variety of instructional formats, resulting in pressures for more, and with an important institutional cost impact. Simultaneously, faculty recognize that the configuration of 'smart' rooms has a powerful influence on the conduct of instruction. A desire to facilitate collaborative/constructivist learning in such spaces has led Dickinson College and this researcher to devise new models for physical learning spaces, while simultaneously trimming the costs of creating them. This paper presents our developing 'Smart3' (3rd generation) classroom designs, including seminar, mid-sized, and larger spaces. Their rationale, underlying research, and the technological and physical features of these spaces are presented.

A synopsis: The published version of this paper provides a synopsis of the visual and verbal material to be presented at EdMedia 2002.

Background: From their origins twenty or more years ago, 'smart' classrooms have become increasingly routine, are demanded by many faculty, and used quite routinely for a range of tasks. It is necessary to create them expeditiously and economically, yet have them fulfill all routine demands made by those using them. This researcher and Dickinson College have created processes for the analysis of needs and the creation of class spaces that are much streamlined from our earliest days. This report and the accompanying visual and supporting material (to be found on line at http://www.dickinson.edu/~cavenagh) detail our progress to date.

Dickinson's existing 'smart' classrooms provide a computer, a data projector, and a mixture of other components. Some rooms add more computers for group work, others add enough computers for every student. These exist in several configurations. We also retain a few cart-based and laptop systems for flexibility. Altogether we currently support 66 facilities for a faculty of about 200, and this number is growing. Unfortunately, the distribution of such facilities is very uneven. New buildings are equipped at a 95-100% level, while older structures are at 30-35%. There are pressures to increase support in these older buildings, which actually house a very large number of classrooms. These buildings are predominantly used for humanities and social sciences.

A number of the humanities and social science faculty are very much interested in discussion based teaching with much collaborative/constructivist work, while lecturing is much less common than in the past. They often arrange seating in circular or group configurations and want rooms to be flexible. Conversely, the demands of projection tend to force all learners to face a single screen. Our 'smart' rooms need to flex to meet these demands. Finally, groups quite often give presentations, so we need a means of allowing several students to address a class at once, while using technology.

Needs analysis: Dickinson has conducted a formal analysis of needs using several instruments. The first, a facilities utilization study, was carried out by our Registrar and an architectural consultant. Student and faculty surveys yielded detailed insights into the perceived needs of these groups. Room-request data was analyzed to reveal the spatial and time patterns faculty wished to meet, and in turn led to a renovation of the college's weekly calendar to better utilize slack time periods.

The Smart3 configuration: Many of our older smart classrooms were custom-tailored to meet the demands of specific departments. Gradually, we recognized that their inherent variability made the rooms difficult for others to use. Our policies mandate that all classrooms be available for all courses, so some means to simplify and standardize was clearly necessary. This resulted in a core equipment package to be used in all new construction, and to be provided when replacing older equipment. As this represented our
third generation of classrooms, we labeled this core package \textit{Smart$^3$}. The package includes only a computer (Mac or PC), a data projector, a modest sound system, and a combination VCR/CD/DVD player. Much of the equipment is housed in a custom lectern (see photos on web site), which is itself designed to be used either by a faculty member or up to four presenters.

At this writing these components cost in the vicinity of $5500, plus installation, plus any required modifications to the classroom. (Most classrooms are already network equipped, have screens, and adjustable lighting.) We then add other computers, accessories, and furniture as necessary.

The use of a combination VCR/CD/DVD player is an important 'simplifier,' as it requires only a single input to the data projector. The entire operation is controlled by two remotes, one for the projector and one for the player, and the audio package has a simple integrated remote control.

The \textit{Smart$^3$} configuration represents a breakthrough in user convenience, and we have been able to create custom instructions for each classroom by simply cutting and pasting and adding photos of the rooms.

\textbf{Computer-per-user classrooms} are expensive but fairly straightforward. We try to minimize the number of these facilities, and then try to maximize their use. We have explored a number of layouts (see photos on web site), and our most recent room maximized desktop space by using LCD monitors. (Surprisingly, this cost less than using CRTs because of savings in furniture costs.) The costs of multiple computer installations cascade in sometimes surprising ways, such as increased cooling costs, needs for better sound control, and difficult demands on lighting systems. The control of 'sight lines' in such facilities takes particular care and small variations from good design practice can reduce the effectiveness of a room quite significantly. The \textit{Smart$^3$} core components provide an instructor's station.

\textbf{A fascinating challenge: Groupwork classrooms} present our single most interesting challenge and potentially our greatest pedagogical innovation. Making classrooms flexible for different seating configurations restricts both furniture and technology choices. At first glance the use of laptops seems to solve all problems, but our analysis demonstrates that two learners often work badly at a single laptop and three or more face such problems of visibility as to render effective group interaction virtually impossible. Further, moving laptops around within a class is time consuming and places the computers at risk.

This writer has engaged in analysis of group performances when using technology, and this work has resulted in the creation of a range of group workstations with curved fronts that provide eye-to-eye contact among group members, while a large monitor insures good visibility. Distributed around our campus, such stations have repeatedly proved their worth. (This work has been reported previously at EdMedia 2000, Educause 2001, and Educause/Baltimore 2002; see web site for references.) Using this experience as a base, we have redesigned these workstations to be wall-mounted in existing classrooms. Requiring only 10 inches of classroom depth and having folding desktops, 4-6 such units can be distributed around the periphery of a classroom without consuming too much space. Combined with movable tables and chairs in a classroom, an instructor can change room configurations without prior planning, and so can adapt teaching modes to 'the teachable moment.'

\textbf{Dickinson's Smart$^3$ model for classroom evolution seeks simplification, reduction of costs, and increased flexibility.} Simplification results in additional hidden savings such as reduced training time for users, reduced design time, and reduced construction time. Increased flexibility of rooms means that faculty have greater range for their teaching styles, and like the facilities better. It also means that more faculty can use rooms than was the case when we custom-designed every facility. Finally, our use of analytic instruments means we have a much improved understanding of real needs, and can concentrate our development efforts on rooms where they are most needed.

The particulars shown here meet the needs of one campus, but we feel that the underlying principles we have followed have application at any institution.

A Personalized Navigation Tool for Online Listening and Free Browsing: The Glass Engine

Margaret Chan*, Mark Podlaseck, Nancy Alvarado, Edith Schonberg, Robert Hoch, and Susan S. S. Stolfo

*Columbia University, New York, and IBM T J Watson Research Center (margchan, podlaseck, nanaly, edids, rhoch, and sspaha)@us.ibm.com

Introduction
The growing popularity of the World Wide Web (WWW) and the competition in electronic commerce has created a need for online product catalogs. The conventional display approach arranges data in multiple pages and sections; users then traverse a hierarchical tree structure to discover the range of products or services that the site offers. Often, users have to navigate within a complex world of classifications and descriptions, making arbitrary decisions without the slightest idea what, if anything, lie at the end of the path. With each choice, users are shut off to perfectly viable options. Furthermore, the experience of traversing multiple paths and viewing many pages may draw users away from the context of the entire product space, causing disorientation and distraction. In fact, after security concerns, navigation problems are the second most cited reason for not shopping online and contributing a significant aspect to the users' negative web experience [1]. We argue that it is important to create interfaces that support interactive product browsing on the Web, and promote enjoyable and productive user experiences as e-commerce sites continue to flourish. In this paper, we describe the Glass Engine, an innovative single-page interactive visualization developed at the IBM T J Watson Research Center in conjunction with the composer, Philip Glass. This multi-attribute electronic music catalog invites users to view, browse, and manipulate a large repository of items with common attributes according to their interests and affinities and at their own pace.

Related work
For the past two decades, research has explored the application of interactive graphics and visualization techniques which facilitate the ready comprehension of large information sets. Some of the new visualization techniques include: Tree Maps (Johnson & Shneiderman, 1991) [2], the Perspective Wall (Robertson, Mackinlay, & Card, 1991) [3], Cone Trees (Robertson, Mackinlay, & Card, 1991) [4], Fisheye Views (Furnas, 1981, 1986) [5, 6], and Hyperbolic Browser (Lamping & Rao, 1995) [7], Münzner et al., 1997) [8]. A number of websites also specifically use a variety of visualization techniques to present large amounts of information online, e.g., “Map of the Market” at Smartmoney.com [9] and the Sony Music web site [10]. Using a rectangular grid of boxes, “Map of the Market” offers a quick view of over 600 stocks. Nevertheless, by using two dimensions to represent a single variable, it does not provide an optimal depiction of multidimensional data. The Sony Music site provides the user with a ThinkMap displaying the links among the themes of songs, which are represented by circles. However, users are not allowed to download or sample the music.

Design rationale
Our project builds on Inselberg’s work on the parallel coordinate visualization technique [11] and Ahlberg, Williamson, and Shneiderman’s research on the Alphaslider selection tool [12]. In parallel coordinates plots, a vector intersects multiple parallel axes to define a point in n-dimensional space, and multiple vectors representing an array of data points can reveal interesting patterns in the data. One of the goals for our multi-attribute online catalog is to address the problem of multiple look-ups. We decided to adopt a single-page arrangement that displays the entire musical work of Philip Glass with all attributes sorted independently. Equipped with a flexible overview of all his works, users can navigate the entire product space without following a pre-set sequence of choices. By selecting the desired attributes and their values, users can restrict the display to the relevant data set.

While we cannot anticipate the needs or intent of every user, we strive to present a dynamic multi-attribute online catalog with an open structure that encourages discovery-based browsing. Thus, users are engaged to freely browse, explore, and manipulate the product space on their own term and at their own pace.

Key features
The display is divided into two halves (Figure 1): the top half is composed of 3 sliders, each representing a single characteristic of the whole musical work; while the bottom half incorporates 5 additional sliders representing the corresponding track numbers of the works and the attributes pertaining to the tracks of the works.

![Figure 1: The Glass Engine](image)

The sliders on the top half of the display are:
- **Title** – arranged alphabetically
- **Date** – date of copyright
- **Length** – in hours, minutes, and seconds

The sliders on the bottom half of the display are:
- **Joy** – emotional effect from low to high
- **Sorrow** – emotional effect from low to high
- **Intensity** – emotional force from low to high
- **Density** – complexity of orchestration from low to high
- **Velocity** – perceived tempo of the track/work
Furthermore, users can fine-tune their navigation (such as accessing the previous work or the next work) by clicking on the back/next buttons above the slider. Users find this particular function practical and necessary when the plotted works are dense. The Glass Engine allows users to perform two kinds of filtering: linear and categorical. Linear filtering is accomplished by pulling tabs from the endpoints of the sliders. For instance, one might move the endpoint "2001" on the Date slider to "1990," effectively hiding all works written after 1990. Categorical filtering (Operas, Symphonies, etc.) is accomplished through selecting View: all work type from the toolbar; users can then select their desired category from a pull-down menu.

In addition, the Glass Engine allows users to navigate all of Glass's works by music characteristics, (e.g., joy or tempo). In the bottom part of the display, users can navigate along the tracks that are, for example, happy or slow or densely orchestrated. In addition, using the endpoint filters, it is possible to navigate solely through the tracks that satisfy multiple criteria, e.g., happy, slow, and densely orchestrated (i.e., navigate or browse the entire product space with multiple criteria specified). Bookmarking is another well-received feature of the Glass Engine. By selecting Favorites from the toolbar, users can bookmark works or tracks of interest to return to them conveniently. The Glass Engine also facilitates comparisons among works and tracks. Since the works are displayed as patterns of sliders, users can compare the values of musical attributes by observing screen changes in slider patterns. In short, browsing and interactive navigation with sliders simplify free exploration; if a selected piece is not what the user expected, the operation is reversible by just sliding the bars in the opposite direction. Finally, the Glass Engine allows novice users to begin browsing with little training, while providing expert users with powerful features such as the ability to perform multi-criteria searches.

Implementation

The Glass Engine interface is a Java applet. Since Java applets are often large, slow to download, browser-dependent, or require additional plug-ins, we restricted the applet to what is supported in jdk1.1.8 which is a version commonly supported by most browsers. The applet can be downloaded quickly and requires no additional plug-ins to run. All catalog data is downloaded with the applet. The music is hosted at a different site observing screen changes in slider patterns. In short, browsing and interactive navigation with sliders simplify free exploration; if a selected piece is not what the user expected, the operation is reversible by just sliding the bars in the opposite direction. Finally, the Glass Engine allows novice users to begin browsing with little training, while providing expert users with powerful features such as the ability to perform multi-criteria searches.

Ongoing usability study

A usability study comparing users' performance and experience with the Glass Engine and a hierarchical interface was conducted at IBM Research in August 2001. Amazon.com was chosen as the control interface because of its hierarchical structure and diversity of products offered. Sixty-one subjects participated in the study. Three dependent variables were measured: knowledge acquisition, music identification, and user satisfaction. Results of the usability study showed that the Glass Engine (GE) group achieved significantly higher overall accuracy than the hierarchical interface (HI) group in both the knowledge acquisition and music identification tasks (t(59)=5.076, p = .001). With respect to user experience, the GE group found it easy to find the music using the Glass Engine and gave significantly higher satisfactory ratings than the HI group on their experiences with the interface (t(59)=5.294, p=.000). Finally, 74% of the participants in the GE group would like to learn more about Philip Glass as opposed to 60% of the subjects in the HI group who would like to do so.

Conclusion and Future Direction

In this paper, we describe the Glass Engine, a novel single-paged, multi-attribute electronic catalog, which presents users a personalized navigation tool to view, browse, and manipulate a large repository of items or products with common attributes. By including as many possible aspects of the composer's music, the users' navigation through his works may be guided by their personal interests, associations, and affinities. Empirical studies in progress point to a possible correlation between the free-form navigation made possible with tools like the Glass Engine, and learning and retention. Another set of empirical studies comparing users' performance and experience with the Glass Engine and other innovative visualization systems is underway at IBM Research. The final analysis of the study will hopefully shed light on the research question: Can advanced user interfaces be successfully employed to give users a new and comprehensive view of large product spaces on the Web?

Assessing and Analyzing the Effects of WBLP on Learning Processes and Achievements: Using the Electronic Portfolio for Authentic Assessment on University Students' Learning

Chi-Cheng Chang
Institute of Technological and Vocational Education
National Taipei University of Technology
Taipei, Taiwan, ROC
f10980@ntut.edu.tw

Abstract: A Web-Based Learning Portfolio (WBLP) was evaluated through practical teaching process to understand if the WBLP system helps students to grasp the learning process and enhances learning outcomes. The evaluation results reveal that this WBLP system has been more useful for them to obtain the feedback from other students than from their teachers. It reflects the fact that the feedback from other students has been helpful for them and has thus become the necessary component to help them in learning. Next step, we will conduct the further empirical study in terms of learning effects for the system.

Research Background

Portfolio has been used to gather the learning activities of students in various aspects as well as the works of students with one purpose in mind. It allows the teachers, students, or their parents to understand and evaluate the learning process, improvement situation, and academic achievement of students. It may also be used as evidence for the pupils to reflect on their learning and the changes in their comprehension during the study process. Portfolio may provide the following benefits (Hewitt, 1995):
1. It may demonstrate students' growth and improvement situation.
2. It may encourage students to set up learning goals.
3. It may provide the hard evidence concerning students' efforts.
4. It may show students' performance or works.
5. It may serve the purpose for job application or school application.
6. It may help the faculty to review students' learning progress.
7. It may serve to inspire the teacher and understand students' performance.
8. It stimulates students' introspective thinking and enhances self-assessment (Smith & Tillema, 1998; Wade & Yarbrough, 1996; Carroll, Potthoff & Huber, 1996; Vavrus, 1990).
9. It encourages students' learning interest, builds up students' self-confidence, and assists students to know more about themselves, and develops writing skill as well.
10. It encourages students' participation in cooperation, and increases their self-esteem (Mullin, 1998).

Portfolio method emphasizes that a learner participates actively and thus establishes the learning results of his/her own concern. Therefore, its development process whether it be instructed by teachers or established by students' own accord, shall both attain the goal of encouraging the learners to be responsible for his/her own learning and to grasp all the goals of learning activities. Furthermore, portfolio assessment was originally designed as an authentic assessment approach meant for the improvement of the traditional pencil-paper tests. Thus, the assessment is real and active. In contrast with the traditional way of assessment, portfolio assessment pays attention not only to the results but also the processes involved. Since learning, teaching, and evaluation comprise of the integrated activities that shall go hand in hand, hence portfolio approach is actually a better way to grasp the complexity of learning processes. It also allows the learners or teachers' introspection to take place. It may also help to reflect on the overall learning and teaching process, so as to give feedback and offer suggestions, thus to benefit the learning in the genuine way. In general, portfolio possesses the following characteristics or features (Wade & Yarbrough, 1996):
1. Developmental: portfolio represents a certain period of students' growth and learning. Portfolio is the long-term accumulated learning results, not meant for short-term goals. Hence, it is actually an on-going process in its development.
2. Dual-valued: portfolio offers both the teachers and students the value of two-way interaction. It allows a learner the opportunity to reflect and record his/her own learning process. It also offers teachers a good approach or method to evaluate students' growth and achievements.
3. Selective: portfolio offers students the opportunity to choose, so that students may self-determine what kind of contents that they want to put in the portfolio and how to organize the whole portfolio. It also allows students to set up the standard or basis for evaluation/ assessment.
4. Authentic: portfolio incorporates the genuine works or performances of students. Traditional tests normally cannot reflect a student growth or potential in all aspects, but portfolio may demonstrate solid learning results and thus offers an authentic way of learning.
5. Reflective: portfolio may reveal the evidence of self-reflection. Thus learners may review his/her own work, then to set up further goals through such a reflection. It may also help to review the previous efforts, and compare them with the actions afterward, for better understanding of his/her improvements or growth.
6. Individual: portfolio is a personal learning and growing record based on individual ways of choices and organization. Consequently, it
reflects personal contents and style in students' personal portfolio.

7. Interactive: a learner may share with his/her teachers and peers through personal portfolio, and thus seeking guidance and suggestions. In this way the development and establishment of portfolio may be regarded as the process of cooperative interactions.

Other than that, portfolio also possesses the characteristics of self-regulated learning and self-directed learning (Fischer & King, 1995; Smith & Tillema, 1998), this is due to the fact that a portfolio allows the learner to self-determine his/her learning goals, strategies, and contents and then records them. Thus the role of scholars is merely to assist and provide feedbacks. That is why it would encourage a learner to become an independent, self-directed person through the development of personal portfolio.

The Web-Based Learning Portfolio (WBLP) that has been structured through web interface and also has gone through the different stages of analysis, design, development, and test is now being established. The effects of the WBLP in students' learning are the issue worthy of our analysis and investigation. With the above pre-requisite in mind, this research hopes to achieve the following goals:
1. To assess the perceived effects of the WBLP, and analyze its impact on students' learning process.
2. To propose the suggestions for future research direction based on the results of evaluation.

Web-Based Learning Portfolio

This WBLP is mainly used to provide students with a web-based user environment. It would help students to complete their individual portfolios through simple, easy-to-use interface for necessary guidance. It also allows the teachers and students to browse their classmates' portfolios, and to give their feedback or assessment opinions. The contents of this WBLP include the following seven major items: the basic information of students, the learning goals of students, the works of students in a course, the records of students' self-reflection or self-assessment, records of teachers' feedback and assessment, records of peer feedback and assessment, personal web page of students. In addition to the above-mentioned, in order to support students to create and browse the portfolios, as well as to facilitate and meet the needs for teachers to inspect and evaluate students' portfolios, the functional areas of WBLP system consists of the following eight major items: Portfolio Browse, Portfolio Creation, Portfolio Guide, Portfolio Discussion Board, Portfolio Bulletin Board, Portfolio Suggestion Board, Student Data Maintenance, System Management (Chang, 2000; Chang, 2001). These functional areas mainly provide the following functions to the portfolio (as shown on Figure 1):
1. The function for students to conduct the various productions of portfolio contents.
2. The function for teachers and students to browse the portfolios of other students or peers.
3. The feedback and assessments of teachers as well as the feedback and mutual assessment mechanism among students themselves.
4. The on-line guidance and illustration for students to create portfolio contents.
5. The searching and management function of students' personal information.
6. The asynchronous discussion channel of portfolio creation process.
7. The opinion feedback channel for students in using the system.
8. The updated system announcement or course information concerned.
9. The function for teachers to manage student information and announcement information.

Design of the Research

We use an established Web-Based Learning Portfolio (WBLP) on an undergraduate course in university. Through practical teaching process, we may evaluate if the WBLP helps students to grasp the learning process, if its enhances learning outcomes. The evaluation consists of user evaluation, user in-depth interviews, and expert evaluation. The evaluation also helps to understand the difficulties and problems of this system in its application and its possible impact on students' learning.

The user evaluation method had been conducted one and half month after the WBLP system implementation. It was carried out through the evaluation questionnaire designed by the researcher. The questionnaire was distributed in several copies to a class of 35 students who were taking the course of "Computer and Instruction" in a Pre-service Teacher Education Program. This research has designed its own questionnaire for evaluation (as shown on Table 3). The questionnaire primarily asked the questions of the WBLP impact on the learning process. The contents of this questionnaire are based on relevant literatures and discussions of scholars and experts. They have gone through the process of examination for validity and reliability. The questions have been presented based on Likert's five-point scaling method. That means the choice for answer is: strongly agree, agree, average, disagree, and strongly disagree.

In order to understand the WBLP impacts on students' learning in depth, so we supplement the study through the researcher self-designed "Questions Listing of User In-Depth Interviews" after the completion of user evaluation questionnaire analysis. Interviews in-depth would then follow up to get to know the opinions and suggestions of the users concerning the unresolved answers and controversial issues that could never be revealed through the previous questionnaire. Targeting for the unresolved questions and the controversial issues of the previous questionnaire of user evaluation, in-depth interviews were then conducted on 5 students selected randomly after the completion of questionnaire analysis work in order to deeply understand the users' opinions and suggestions.

Three experts were being invited to conduct the expert evaluation (including the course instructor, a portfolio assessment expert, and a web technology expert) to use this WBLP on-line. The evaluation work was then conducted through interview method after one week. In terms of expert evaluation, interviews were conducted based on the researcher's self-designed "Questions Listing of Expert Interviews". In this way that we got to understand the expert opinions in regarding the WBLP impact on learning and teaching.
Validity and Reliability of Questionnaire

Validity refers to whether a tool for measurement/survey that may achieve its intended functions or purpose. The questionnaire of user evaluation in this research has gone through the processes of pre-test and pilot-study to verify the validity of the questionnaire.

For attaining the goal of questionnaire validity, it was necessary to consult two expert/scholars of portfolio assessment and web technology, and one teacher who instructed the course after the completion of the questionnaires for their opinions on revising the framework of said contents, words and expressions relating to the issues, etc. The suggestions for revising the questionnaire include: increasing the contents of the questionnaire, more articulate in the expressions of questions, word polishing, etc. Then could the contents of the questionnaire be able to attain the goal originally intended for the effectiveness in its measurement/survey. Through the implementation of such a method, this research meets the needs of measurement/survey tool efficiency. The above process involved is the so-called expert validity.

We may achieve more complete validity verification through the further process of pilot-study. We picked up 5 students randomly for the purpose of this research at that time to conduct pilot-study based on the rough draft of the questionnaire. We hoped to go through such a pilot-test and render the results to the researcher to get to know if the questionnaire could effectively measure/survey the purpose intended for this research, and to revise any inappropriate whatever necessary. The opinions or feedback for revision include the clarification of some questions and word polishing, etc., so as to present the questions in the way better understood by students who were answering the questionnaire.

Reliability refers to being consistent and steady in terms of measurement/survey method. In this way we could understand the extent or degree of reliability for measurement/survey instruments. In order to attain the reliability goal of this questionnaire, we conducted the reliability test of Cronbach's alpha coefficient by using the contents of the above retrieval questionnaires. The extent or degree of consistency within the questionnaires could thus be determined. Then we could determine if the research measurement tool possessed certain degree of reliability. The Cronbach's alpha coefficient of formal questionnaire after revision is equal to 0.8346 (n = 35). This shows that the reliability level of this research has attained a rather reliable level.

Results and Discussions

User Evaluation

User evaluation consists of survey and interviews. Tables 1 list the statistics results of each evaluation item within the questionnaire. Among the 25 evaluation items of Table 1, other than the later debut of the Discussion Board (came out only about one week prior to the evaluation) that has led to the insufficient understanding and use of its function, and thus resulted in the mean of this two items both lower than 4 (3.83 & 3.87 respectively) for Item 16 -- the articles of Portfolio Discussion Board enhance my growth in learning and Item 17 -- the feedback on the Portfolio Suggestion Board have been helpful for me to overcome the difficulty in producing personal portfolio. As for the other 23 items of survey, the degree of agreeability mean is higher than 4, and most users are either agree with the statement or very much agree with it. The means of 6 items (Item, 12, 18, 19, 20, 24, 25) are even higher than 4.5, and 90% of the users regard them very helpful for their learning.

From the survey results, it appears to be that most of the users are rather agreeable that this system has been helpful for their learning process or learning outcomes, and thus have come out with positive appraisal for this system. As for the questions in regarding to whether the browsing of other students' portfolio, learning goals, works, basic information, personal web page, etc. may help them in some way (from Item 6 to Item 14), most students regard that it has been most helpful for them to browse other students' works. The mean for this question is as high as 4.53. As high as 93% of the students regard that the quality of their own work can be improved by such an emulation through the browsing of others' works (Item 12). 94% of the users regard that it helps to understand the merits and shortcomings of other students' learning by browsing other students' portfolio (Item 7). 97% of the users regard that it enhances their own academic growth and improvement by browsing other students' portfolios (Item 8). All these survey results have revealed the fact that the use of portfolio has really helped the users in learning.

| Table 1: Percentages and means of student agreement in WBLP impacts on learning process |
|---|---|---|---|---|---|
| Impacts on Learning Process | Percentages of Agreement (%) | 5 | 4 | 3 | 2 | 1 |
| 1 Set up learning goals may help me with the direction in self-learning | 27 | 53 | 20 | 0 | 0 | 4.07 |
| 2 The uploading and gathering of course works helps to reveal my genuine learning outcomes | 37 | 60 | 3 | 0 | 0 | 4.33 |
| 3 The writing process for self-reflection and assessment records help me to grasp and reflect on genuine learning process | 37 | 53 | 10 | 0 | 0 | 4.27 |
| 4 Teacher feedback helps me to reflect on my merits and shortcomings in learning | 53 | 40 | 4 | 3 | 0 | 4.43 |
| 5 The feedback from peers help me to reflect on my merits and shortcomings in learning | 47 | 43 | 7 | 3 | 0 | 4.40 |
| 6 Browsing classmates' portfolios helps me to reflect on the merits and shortcomings in my learning | 47 | 43 | 7 | 3 | 0 | 4.33 |
Browsing classmates' portfolios helps me to understand the merits and shortcomings of my classmates in learning

Browsing my classmates' portfolios helps me to grow and improve in academic achievements

Browsing my classmates' portfolios helps me to motivate me for the learning of this course.

Browsing classmates' learning goals helps me to understand classmates' work effort, and thus enhances that of my own

Browsing my classmates' works helps to upgrade the quality of my works

Browsing my classmates' basic information helps me to understand my classmates better

Browsing my classmates' personal web page helps me to better understand my classmates and thus enhances relationships with them

The information in Portfolio Bulletin Board helps me to better understand this course

The articles of Portfolio Discussion Board help my academic growth

The message feedback in Portfolio Suggestion Board helps me to solve the problems that I have encountered in portfolio creation

It helps me to know about the learning outcomes of my classmates by using this system

It helps me to know about my teacher feedback and suggestions by using this system

It helps me to know about my classmate feedback and suggestions by using this system

It enhances my interactions and exchanges with my classmates by using this system

It helps me to better understand my growth and improvements in the course by using this system

It helps me to better understand the growth and improvements of other classmates in this course by using this system

It helps me to learn this course by using this system

I hope to use this system in other courses as well

The most positive feedback comes out in terms of the overall benefit in using this system (from Item 18 to Item 24), most of the students agree that by using this system, it helps them to better understand other students' learning achievements (mean = 4.67, Item 18), allowing them to obtain the feedback and suggestions of other students (mean = 4.57, Item 20), and benefit their learning of the course from the portfolio (mean = 4.67, Item 24). 100% of the users regard it useful to utilize the portfolio to get to know the learning achievements of other students (Item 18). 97% of the users regard it helpful to obtain the feedback and suggestions of other students through this system (Item 20). As high as 97% of the users expressed that it helps them to learn the course by using this system (Item 24).

Furthermore, one very interesting phenomenon is when being presented with the question (Item 19 and Item 20) that whether using this system helps them to obtain the feedback from teachers (mean = 4.53) or from the other students (mean = 4.57), the results show that this system has been more useful for them to obtain the feedback from other students than from their teachers. We deduce that one of the reasons may be that students generally hold higher expectation for feedback from teachers. Another reason may be that the contents of teachers' feedback are not as much as that of other students'. Since the teachers have to answer and feedback to all students while the students only need to feedback to a few selected peers. The above survey results reflect the fact that the feedback from other students has been helpful for them and has thus become the necessary component to help them in learning.

On the average, as high as 88.84% of the users feel that the system has been helpful in their learning process and outcome. Only 2.76% a small percentage of the users think otherwise. This shows that the implementation of portfolio truly helps most of the students in academic growth and improvement with great efficiency. Thus it has created positive impact on learning process and outcome. Figure 2 shows the distribution of means for student agreement percentages in WBLP impacts on learning process.

</table>

The above survey results reflect the fact that the feedback from other students has been helpful for them and has thus become the necessary component to help them in learning.
To sum up the results of the above user evaluation, the appraisal for impact on learning process is high (mean = 4.33). To learn from the lesson above, teachers should give much more encouragement to their students, and pay more attention to the difficulties that the students may come across in the implementation process of future portfolio assessment.

User In-Depth Interviews

We conducted in-depth interviews with 5 users (who were chosen randomly from the students who had been taking the course) after the statistics that have come out based on the suggestion items and questionnaire results to deduce or conclude a few important user opinions or suggestions.

In terms of the impact on learning process, most students regard that the overall design of the WBLP system is good. They are able to get to know other students' learning processes, learning experiences, and thus enhance their learning of the course through their browsing. This WBLP system provides the gathering and browsing to access to other students' works, and thus allows one to get to know better about his/her merits and shortcomings. Then one can improve accordingly in learning. Some students regard that to set up learning goals may allow themselves to be ready for individual learning direction. However, there seems to be no direct evidence reflected through our assessment standard to support the assumption that such a learning goal set up may help them in terms of assessing their final learning results. Hence, its real purpose and function seems to be ambiguous. In addition, introspection and self-assessment help to review the process in students' learning or producing their works. It would allow the students to discover the areas that they may improve. As a result, it enhances learning for maintaining such a reviewing process.

Expert Evaluation

Upon the completion of this system establishment, we had invited 3 experts (including a portfolio assessment expert, an Internet technology expert, and the course instructor) to use this system. The researcher was then interviewing them one week later. In this way we have obtained the valuable opinions and suggestions of these experts.

These experts also answer the following questions, such as: "whether this system has been helpful for students' learning and teachers' teaching?" "Is it possible to provide an effective and appropriate portfolio production and browsing environment in order to allow both the teachers and the students to better understand the genuine learning processes and results of students?" Some experts regard that this WBLP system provides the opportunity for gathering students' works for emulation among the peers. Consequently, the practice will surely enhance students' learning result. The introspection and self-assessment records of students would allow the teacher to better understand students' prerequisite ability as well as the practical issues or problems that students have encountered, and also students' achievements in learning. This will help to attain the goal of being more objective in student assessments, and it will also help the teacher to adjust his or her teaching method in the future. Some experts point out that the works that students have presented via this WBLP system are mainly the final completed works of students, but the processes of such productions in terms of gathering and demonstration shall also be incorporated as well. Hence, the production processes or the on-going works shall be demonstrated as well. Finally, the system has to improve its management functions in terms of supporting the teachers to perform on-line assessments for students' works, and to track the status of students' using the services of this system through on-line records and statistics.

Summaries and Conclusions

The characteristics of the WBLP is meant to allow the teacher and students' genuine understanding of the individual learner learning process and outcome, and thus to enhance the feedback and interactions among teachers and students. Furthermore, it helps students to get to know the merits and shortcoming in his/her own learning, also the difficulties and problems involved, thus to pro-
mote the integration of teaching, learning, and assessment.

As high as 88.84% of the users regard the electronic portfolio system has benefited their learning. As high as 93% of the students regard that the quality of their own work can be improved by the emulation through the browsing of others' works (Item 12). 94% of the users regard that it helps to understand the merits and shortcomings of other students' learning by browsing other students' portfolio. 97% of the users regard that it enhances their own academic growth and improvement by browsing other students' portfolios. The evaluation results also show that this WBLP system has been more useful for them to obtain the feedback from other students than from their teachers. It reflects the fact that the feedback from other students has been helpful for them and has thus become the necessary component to help them in learning.

Whether the use of web-based portfolio system will definitely enhance students' self-regulated learning, self-directed learning, enhancing the ability for self-reflection, encouraging learning motivation, etc. are all the interesting issues worthy of our further research and verification. Therefore, we will conduct the relevant future experiment study in terms of the practical applications in teaching and learning efficiency for web-based portfolio system.

Record desktop activity as streaming videos for asynchronous, video-based collaborative learning

Chih-Kai Chang
Department of Information Management
Da-Yeh University
Chang-Hua 515 Taiwan, R.O.C.
Email: chihkai@mail.dyu.edu.tw

Abstract: As Web-based courses using videos become popular in recent years, the issue of managing audio-visual aids becomes noteworthy. In general, the contents of audio-visual aids may include a lecture, an interview, a featurette, or an experiment etc. Then, the audio-visual aids of Web-based courses are transformed into the streaming format that can make the quality of Internet-based videos acceptable to learners using a limited bandwidth. Although streaming technique enables the learners' accessibility of audio-visual aids over Internet, the usage of audio-visual aids is still totally adhere to instructors' perspectives. In fact, distance learners can contribute ideas not only in text format, but also in audio-visual format. However, previous researches did not consider the feasibility of audio-visual aids contributed from distance learners. The objective of this paper is to argue that the usage of audio-visual aids from distance learners' perspectives should be considered in designing Web-based course. To demonstrate this concept, this paper first introduces a screen camcorder tool, which enables learners to record screen activity as videos in standard format or streaming format. Then, a collaborative learning strategy, called Jigsaw II, is applied to encourage expertise group contribute streaming videos for training other learners. Finally, a preliminary survey of technology acceptance is implemented on 37 learners. Results confirm the feasibility of audio-visual aids contributed from distance learners.

Introduction

As Web-based courses using videos become popular in recent years, the issue of managing audio-visual aids becomes noteworthy. It is not a new idea of using videos for distance learning (Kozma, 1986; Zigerell, 1991; Levne, 1992). For instance, a distance learning course may conventionally transmit videos by videotapes, cable TV, broadcast TV, or VCD. Although researches indicate that the face-to-face (synchronous or asynchronous) situation is not an essential factor of learning performance, some reports show that distance learners prefer video to other media. Hence, a distance learning instructor may often provide teaching video to distance learners by Internet in recent years.

The contents of audio-visual aids may include a lecture, an interview, a featurette, the operation of a machine, or an experiment etc. In fact, the contents of audio-visual aids are discipline-dependent. For instance, the major portion of the video contents for a Physics course may be used to demonstrate an experiment. Anyway, the instructor is the only provider of audio-visual aids in most Web-based courses. Furthermore, very few instructors were involved in planning or designing the teaching videos. Instead, audio-visual aids are considered as replacements of learning activities that can not be implemented in a classroom situation. As Benney said “Most certainly video is a successful medium for taking students into the field to observe facts, processes and emotional events which would otherwise be impossible to see and experience” (Benney, 2001).

To provide teaching video over Internet, the video signals should be transformed into the streaming format that can make the quality of Internet-based videos acceptable to learners in a limited bandwidth. The streaming format means that the requested video signals are stepwise transmitted from server to clients. The most famous commercial products for providing streaming-video functionalities are the Windows media server of Microsoft™ and the realmedia server of RealNetworks™. Consequently, a Web-based course should prepare contents of videos, transform videos into streaming format, and setup a media server to provide teaching videos through Internet.

Existing learning strategies of video-based instruction can be categorized by three types: (1) passive watching, (2) learn/practice while watching, and (3) learn/practice after watching (DeMartino, 2001). The
passive watching strategy means that students do not be engaged in a discussion activity or a learn-by-doing activity. The passive watching strategy generally results in poor long-term outcomes. The learn/practice while watching strategy means that a student or a learning group can pauses, stops, forwards, or rewinds a video clip to self-pace learning by joining a discussion or learn-by-doing activity with learning partners. The learn/practice after watching strategy means that the discussion activity or learn-by-doing activity following a teaching video provides a reflective opportunity to deepen long-term outcomes.

No matter which type of learning strategies for video-based instruction is used, the usage of audio-visual aids is totally adhere to instructors' perspectives. Distance learners are not expected to be able to provide videos to depict an idea or communicate with others. Hence, a distance learning instructor tends to provide BBS, email list, or WBB (Web Bulletin Board) to support asynchronous, collaborative learning after watching an instruction-video (Repenning, Ioannidou, & Phillips, 1999). In fact, distance learners can contribute ideas not only in text format, but also in audio-visual format. However, previous researches did not consider the feasibility of audio-visual aids contributed from distance learners.

The required computer hardwares for videoconferencing, such as video camera, video capture card, and network bandwidth etc., will be a considerable expense for a distance learner. Consequently, most Web-based courses do not implement completely video-based communication environment because of considering distance learners' financial burden. Moreover, video-based instruction is generally regarded as a synchronous communication tool or a passive medium such as recorded lectures. However, a noteworthy idea is that distance learners can contribute audio-visual aids in their own way instead of an instructor's way. In other words, distance learners can record computer screen activity as video and oral explanation as audio in a video-based communication environment without additional computer hardware. Consequently, distance learners can join the process of asynchronous, video-based instruction to ease the general problem, that is instructors tend to spend too much time lecturing, of video-based instruction.

To demonstrate this idea, the following section first introduces a screen camcorder tool, which enables learners to record screen activity as videos in standard format or streaming format. Then, a collaborative learning strategy (Jigsaw II), which was proposed by Elliot Aronson (Slavin, 1995; Aronson & Patnoe, 1997), is applied to encourage expert group contribute streaming videos for training other learners. Finally, a preliminary survey of technology acceptance was investigated and results are shown and discussed.

Computer Desktop Camcorder

Many commercial products can record computer desktop activity and voice from a microphone as videos in standard AVI formats, for instance Lotus™ ScreenCam[1], TechSmith™ Camtasia[2], and Hyperionics™ HyperCam[3] so on. Computer "desktop activity" means that learners' every action, such as open a file, execute a program, show slides for a lecture, use browser, and even all mouse-pointer movements so on, will be recorded as a video Furthermore, learners' explanations during the aforementioned interval of actions can be recorded as the audio track of a teaching video through the microphone of a computer. Because computer desktop or screen is like the viewfinder of a video recorder, aforementioned softwares are called desktop camcorder or screen camera.

Originally, desktop camcorder tools are used to train users for new software by an kind of active style. Hence, most desktop camcorder tools includes the following features:

(1) Users (here it means learners) can determine the video capture area.
(2) Users can use zoom effects to zoom in or zoom out during capture.
(3) Users can annotate a caption on the captured video.
(4) Users can use a microphone to input audio during capture.

To get an overview of computer desktop camcorder, TechSmith™ Camtasia is used for demonstration. Figure 1 illustrates use TechSmith™ Camtasia to capture slides, mouse movement, audio from microphone input as teaching videos. Instructors can press the capture hotkey or click on the record button (the red one) on the toolbar to start recording. During recording, Camtasia recorder can be minimized to avoid obstructing learners' lines of sight. Instructors can stop the capture by a hotkey and save the captured video to a file.

---

In general, the captured videos are produced in standard AVI formats. However, the captured videos can be easily transformed into proper streaming formats that depend on the technology for streaming media services, i.e., the Windows Media Server of Microsoft® or the RealMedia Server of RealNetworks®. Both companies provide freeware to transform videos of standard AVI formats into proper formats. Fortunately, TechSmith® Camtasia tools can support both transformations. Consequently, users can easily produce streaming videos no matter which technology for streaming media services is used.

Collaborative learning strategy

The elements for a collaborative learning strategy include heterogeneous grouping, interdependence, individual accountability, and group processing (Warschauer, 1997). Those elements are used to make sure learners will try to help each other. Some researches developed learning environment for implementing collaborative learning strategy (Brandon & Hollingshead, 1999; Persico & Manca, 2000). However, there is not any collaborative learning environment based on streaming, asynchronous, and video-based technique instead of Web-based or videoconferencing techniques. Furthermore, collaborative learning strategies are also required to promote learning motivation and learning performance when we apply the novel technique to distance learners.

Before developing prototype system, another question arises from 'which one of collaborative learning strategies in literature is more suitable for computer desktop camcorder technique than others'. It is difficult to prove that a collaborative learning strategy is more suitable than others are because no literature reports using computer desktop camcorder technique in collaborative learning activities. Furthermore, the selected collaborative learning strategy should be able to encourage distance learners contributing instructional videos to training learning partners from distance learners' perspectives. In consideration of those issues, the Jigsaw II collaborative learning strategy is chosen because the expertise groups mechanism of Jigsaw II can support distance learners to master a learning topic. Then, we can encourage members of an expertise group to sharing their knowledge in streaming video style.

It is assumed that an instructor would like to construct a collaborative learning strategy, for example Jigsaw II, on Web. In general, there are three steps in the Jigsaw II collaborative learning strategy. First, distance learners are heterogeneously assigned to groups according their cultures, mother tongues, and grade point averages so on. Hence, the groups of first step are called heterogeneous groups or jigsaw groups. Then, every distance learner of a heterogeneous group is respectively assigned to a study group for mastering a specific learning topic. Distance learners collaboratively study an expertise or learning topic to support each other.
becoming an "expert" of a topic in a study group. Consequently, the study groups of step two are called expertise groups. Finally, every member of an expertise group will return to his/her own heterogeneous group. After distance learners return to heterogeneous groups, every member of a heterogeneous group is accountable for teaching a learning topic, which he/she learned in an expertise group, to the other members. In other words, each student should present a well-organized report to teaching a learning topic when he/she comes back to his/her heterogeneous group.

The required processes, heterogeneous groups, and expertise group for Jigsaw II collaborative learning are illustrated in Figure 2. From the perspective of a distance learner, computer desktop camcorder can support him/her to tutor learning partners in a heterogeneous group by video-based instruction. To apply video-based instruction, a distance learning instructor should setup a media server as a streaming video provider. Then, distance learners of an expertise group should not only study a learning topic, but also plan a teaching video. Finally, distance learners of an expertise group can produce a teaching video by computer desktop camcorder and upload the teaching video to a media server. Consequently, video-based instruction in a heterogeneous group becomes feasible. The refining part of Jigsaw II collaborative learning is depicted in the right part of Figure 2.

![Diagram of Jigsaw II collaborative learning with video-based instruction](image)

**Figure 2.** Integrating video-based instruction by a desktop camcorder supports Jigsaw II collaborative learning

**Analysis of Preliminary Evaluation**

The evaluation presented in this section attempts to analyze distance learners' technology acceptances of using desktop camcorder for collaborative learning. This experiment was carried out in Da Yeh University and a sample of 37 students (18 females and 19 males) was chosen from a class of information management department. The objective was to figure out how useful and ease of use the distance learners think desktop camcorder is.

A questionnaire, used in Davis’s technology acceptance model (TAM), was chosen as an evaluation tool (Davis, 1989). Davis’s TAM can support managers to understand the process of adopting new technology. One can realize the importance of TAM from this description: "(TAM)...are widely accepted among the MIS research community as tools for evaluating information system applications and predicting usage" (Doll, Hendrickson, &
Deng, 1998) In other words, the results of TAM can provide evidence to be weigh for or against the application of adopting desktop camcorder in collaborative learning. Originally, there are twelve questions classified as two categories (perceived usefulness and perceived ease of use) in Davis’s questionnaire for TAM. In this evaluation, one overall ranking question was added to the original questionnaire. The contents of the questionnaire used in this evaluation are listed as following:

| USEFULNESS | Q1. Using <computer desktop camcorder> in my job would enable me to accomplish tasks more quickly. |
| EASE OF USE | Q2. Using <computer desktop camcorder> would improve my job performance. |
|            | Q3. Using <computer desktop camcorder> in my job would increase my productivity. |
|            | Q4. Using <computer desktop camcorder> would enhance my effectiveness on my job. |
|            | Q5. Using <computer desktop camcorder> would make it easier to do my job. |
|            | Q6. I would find <computer desktop camcorder> useful in my job. |
|            | Q7. Learning to operate <computer desktop camcorder> would be easy for me. |
|            | Q8. I would find it easy to get <computer desktop camcorder> to do what I want it to do. |
|            | Q9. My interaction with <computer desktop camcorder> would be clear and understandable. |
|            | Q10. I would find <computer desktop camcorder> to be flexible to interact with. |
|            | Q11. It would be easy for me to become skillful at using <computer desktop camcorder>. |
|            | Q12. I would find <computer desktop camcorder> easy to use. |
|            | Q13. Overall, I find using <computer desktop camcorder> useful in my job and believe that <computer desktop camcorder> is easy to use. |

Table 1: Contents of the questionnaire for evaluation.

Every question in Table 1 was scored on a 7-point scales, with strongly disagree (1) and strongly agree (7) as the two endpoints. Table 2 depicts descriptive statistics to analyze results of this preliminary evaluation. From the mean of the 13-th question (Q13), most learners agree that computer desktop camcorder is useful and easy to use. Noteworthily, the data show that, on the average, learners' perceived usefulness respondents (Q1~Q6) had relatively lower than learners' perceived ease of use respondents (Q7~Q12). Through an informal interview, students indicate that video-based instruction is not very critical because they are not in a distance learning situation. One student said “it (teaching video) will be very useful in heterogeneous group status if we (learning partners of a heterogeneous group) can not meet one or two times per week”.

Conclusion

Although streaming technique enables the learners' accessibility of educational multimedia over Internet in recent years, the usage of educational multimedia is still totally adhere to instructors’ perspectives. In other words, all teaching videos and audio-visual aids of most instructional website are contributed by instructors or instructional teams. This paper introduces a tool, computer desktop camcorder, to support distance learners contributing teaching videos for collaborative learning. We integrated computer desktop camcorder into a famous collaborative learning strategy, Jigsaw II, as additional supports for heterogeneous group learning. After training distance learners for using desktop camcorder, a preliminary evaluation of technology acceptance is implemented on 37 learners. Results show that most learners agree that computer desktop camcorder is useful for
collaborative learning and easy to use. Most important of all, this paper indicates the feasibility of audio-visual aids contributed from distance learners.

An Interactive Storytelling System for the Pearl of the Desert Exhibit

Computer technology brings flexibility and more interactive into museum exhibition. The characteristic of computer multimedia can present audio, video, graphic, animation as well as text with well-designed program structure. Recently, most of the museums created a multimedia-based learning environment using new computer technology. The goal is to set up new directions of exhibition for visitors to explore, to enjoy, to be inspired as well as to improve their knowledge. This paper proposes an interactive storytelling system which reveals the art collections of the Tunhuang and its historical information based on film theory and computer technology. The collection of visitors’ motion as they interacted with computers is also investigated.

Tunhuang art is one of the most famous artistic works in Central Asia in which Buddha statues are carved and painted. It consists of Tunhuang Grottoes from 4th to the 14th centuries. From the historical view, in the past thousands of years, many stories about these caves in Tunhuang were described in books or magazines. An interesting story as “story about the 17th cave in Tunhuang” would be described briefly as following:

Time: 1900
Place: Tunhuang
Cast: Wang Juan-Lu who is a taoist

Wang Juan-Lu was assigned to take care of the caves in Tunhuang by Chin Dynasty government. His duty was to maintain the painting wall and clean the sandy ground. One day, as he cleaned the 16th caves, the wall crashed suddenly. He found another caves where many important manuscripts of literature, linguistics, philosophy, population, religion, science, medicine, economy, society and so on were collected.

He reported to the Chin Dynasty government. However the officers ignored that with negative attitude. Finally, Wang Juan-Lu traded most of the manuscripts with foreigners under the table.

In order to present the historical information and art collections, National Museum of Natural Science in Taiwan conducts an exhibition called “The pearl of the Desert: The caves of Tunhuang Exhibition” in 1999. This exhibition combines the historical background of Tunhuang with beauty of arts. With the goal of understanding, computer played an important role as an art works presenter, an interpreter as well as a story-teller. The outcome is to entertain the visitors, to enrich the visitors’ knowledge, to inspire their emotion and also to meet their variety needs.

The computer project was well-designed with Interactive storytelling construction. Based on film theory, time, place and cast with animation text were shown on the first scene. Next, the cast Wang Juan-Lu appears and is introduced by himself with speech and animation. The audience are asked to sweep the dust by clicking the mouse on the monitor. The cursor is also
designed to look like a broom. Some incredible feedback such as spiders, rats, and interesting
dialogs appears on the screen as the mouse is clicked. Certainly, the wall would crash as the
audience click certain area on the screen. After the wall crashed, Wang Juan-Lu is moved near
the wall with curiosity and a new cave with lots of manuscripts can be found. After that, he
would ask audience some questions about the information of this new cave in dialog-inquiry
mode. Some manuscripts and art works then can be retrieved in detail with its moving and
zooming images on the computer screen.

Actually, computer not only provides a good solution to preserve the objects in the
exhibition, but also provides the image as clear and real to satisfy individual interests and needs.
A Study of Internet situations with Smileys

Yaowen Chang
Department of Mathematics, Science and Technology
Teachers College, Columbia University
vc371@columbia.edu

Abstract: "Smileys" are part of the Netspeak (Crystal, 2001), which is considered a hybrid of spoken and written languages. Because literacy practices are embedded in contexts (Barton, 1994), online literacy practices should differ depending on the Internet contexts or Internet situations. The current paper intends to validate the conceptualization of "Internet situations". It also aims to refute Crystal's lumping of asynchronous discussion board and synchronous chat as one type of Net situation. Comparisons were made of the frequencies of smileys in three online communication media: instant massager, email, and discussion boards. Findings indicate that "time" and "personal" dimensions to be useful parameters of Internet situations.

Introduction

The prevalence of "faceless" computer-mediated communication (CMC) (Voiskounsky, 1998) has resulted in the development of "smileys" or "emoticons". Smileys are signs meant to mimic the human facial expressions that reflect an individual's emotional state. It has been postulated that the online use of smileys is on the order of compensation for the lack of emotional richness in electronic communication (Crystal, 2001; Voiskounsky, 1998). Crystal (2001) further stressed the essential role of smileys in the emergent "Netspeak."

A discussion of Netspeak – the language of Internet communications – could not do without the context of “spoken” and “written” languages because Netspeak is the meeting point of the two (Crystal, 2001). In an analysis of Netspeak based on seven criteria that differentiate written and spoken languages, Crystal found that Netspeak is closer to written than to spoken language.

Since the development of language and literacy are inseparable from contexts (Barton, 1994), the diversity of possible Net discourse contexts infers the inherent heterogeneity in literacy practices via Internet media. Crystal (2001) proposed four categories of social situations in which Netspeak occurs, calling them "Internet situations." By comparing discourse patterns among different Internet situations to those of spoken and written languages, Crystal concluded that the degree of similarity between Netspeak and written or spoken language is dependent on the context. For instance, it was found that language used in chatroom discourse is closer to spoken language than is that used in Web-page presentation.

As part of Netspeak, the evolution of smileys has also been influenced by social and cultural contexts. Observations on the development of smileys (as well as Netspeak, itself) indicate an emerging divergence – as opposed to convergence – in Net-linguistic evolution. A comparison of the English and Japanese smileys indicates that the differences are deeper than in the "face" value (i.e., the form); variation in socio-cultural values is also evident. For instance, since it is impolite for a Japanese lady to show her teeth while smiling or laughing, a female smile is presented as ‘^_^’ rather than ‘^_^’. Given that the users and the environment are the developmental outcome of the social and cultural contexts, the development of Japanese smileys provides a good example for the social construction of language and literacy practices. While the aforementioned example points out the impact of the cultural context on online literacy practices, the following section examines the role of online situations on the occurrence of literacy events and the defining dimensions of these situations.

Since literacy practices are situation-dependent (Barton, 1994), practices involving the use of smileys should also vary in accordance to the situation. Crystal (2001) lumped the synchronous chat and asynchronous discussion into one Internet situation. Because the lag between messages is one major difference between spoken and written languages, the time factor should play an essential part in the ecology of online communications. Thus, given its asynchronous nature, online discussion would share a higher degree of similarity with e-mail than with online chat. Moreover, discussion board postings are viewed by the public and aim to communicate facts and ideas. When compared to discussion postings, e-mails are more likely to be used for social and unplanned discourse. Thus, given the degree of "personal" involvement, there should be a higher degree of similarity between e-mail and chatroom than between discussion board and chatroom. Furthermore,
spoken languages are enriched by emotional signals, like facial expressions, of which written languages are deprived. Given that the introduction of smileys aims to compensate for the lack of emotional richness, it is postulated that there will be a higher degree of smiley usage in those Internet situations most similar to spoken discourse. Thus, when comparing the usage of smileys in chat, e-mail, and discussion situations, the highest degree of smiley usage would be expected to occur in the chatroom and the lowest on the discussion board.

Method

100 recent postings in discussion boards for three distance learning courses; 100 e-mails for both business and personal purposes; and 100 instant messages were collected. While 18 e-mails and 57 instant messages contain at least one smiley face, smiley faces appear on 15 of the discussion board postings. T-tests were performed to examine whether there are significant differences in the occurrences of smileys across Internet situations. While no significant differences were found between the e-mail and discussion board situations, smileys appeared significant more frequently in instant messages when comparing to the e-mail (t=6.40, df=198) and the discussion board (t=6.85, df=198) situations. Similar findings have been reported in a previous study (Af Segerstad & Ljungstrand, 2002).

Findings

The large smiley difference between chat and discussion implies an inherent difference between the two forms of discourse, which contradicts Crystal’s (2001) categorization. The current findings imply that, while there is a large difference between the chat situation (i.e., instant message) and the other two, that between the e-mail and discussion situations is not as salient. Such findings imply a “time” dimension for Internet situations because, while the use of instant messaging is mostly associated with synchronous CMC, e-mailing and postings in discussion boards are media for asynchronous CMC. Moreover, in the current study, the instant messaging was for personal purposes, while the use of discussion forums was for public purposes (e.g., delivering facts and ideas). Serving both personal and business purposes puts e-mailing in the middle situation between discussion and chat. Such observation further insinuates a “personal” dimension for Internet situations.

The current paper rests on the assumptions that the emergent “Netspeak” exists and that smileys are a sub-component of Netspeak (Crystal, 2001). One major purpose of the study was to validate the conceptualization of “Internet situations” by conducting a case study about the usage of smileys. While findings seem to support the notion of such conceptualization, discussions also point out that the “time” and “personal” dimensions might be two useful parameters to describe Internet situations. It is suggested that future research should focus on refining the conceptualization of Internet situations and their defining parameters. Such efforts would be useful in establishing a conceptual framework, which could aid in untangling the topic of “Internet literacy.” It should be noted that the current study was based on data collected from only 1 subject, which cast doubts on the generalizability of the results. A larger sample will be required to establish the generalizability of the given findings.

Problem-Based Learning in an On-Line Biotechnology Course

J. D. Cheaney, Department of Zoology and Genetics, Iowa State University, Ames, IA, USA jcheaney@iastate.edu

T. S. Ingebritsen, Department of Zoology and Genetics, Iowa State University, Ames, IA, USA tsingebr@iastate.edu

Abstract: Biotechnology in Agriculture, Food, and Human Health is a World Wide Web course developed by Project BIO, a program to develop and share Internet biology education resources, at Iowa State University. This course has been utilizing problem-based learning as a mode of instruction in a unit dealing with pre-symptomatic DNA testing for a genetic disease. Problem-based learning is the use of a "real world" problem or situation as a context for learning. Quantitative and qualitative assessments of student gains in critical thinking, improvements in ability to solve real-world problems, acquisition of knowledge, development of the ability to work productively as a team member, and development of skills supporting life-long learning were analyzed. The current study indicates that problem-based learning is a valid and efficient means of expanding student learning in on-line courses.

Problem-based learning (PBL) is an increasingly integral part of education reform around the world. The essence of PBL can be summarized as the use of a "real world" problem or situation as a context for learning (Duch, 1995). The purpose of PBL is to increase education's relevance to the perceived needs of the professional community, and to increase the problem-solving abilities of graduates, by having design problems presented in class that resemble reality (Cowdroy, 1994). Learning objectives in PBL situations include the development of critical thinking skills, development of a high professional competency, development of problem solving abilities, acquisition of knowledge, development of the ability to work productively as a team member and make decisions in unfamiliar situations, and acquisition of skills that support self-directed life-long learning, self-evaluation, and adaptation to change (Albanese and Mitchell, 1993; Ryan and Quinn, 1994). The student learns in the context of a real-world problem, which may lead to a desire to successfully solve the problem because the student has internalized the problem (Schmidt, 1993). PBL has traditionally been conducted in cooperative learning groups in a face-to-face setting. Less is known about its use in the virtual environment (Camp, 1996).

A problem-based learning approach is being tested in an on-line course entitled "Biotechnology in Agriculture, Food and Human Health" offered by Iowa State University. This is a three-credit survey course that covers biotechnology and its applications as well as associated ethical, legal and social issues. The biotechnology course consists of on-line audio-visual lectures that are modeled after lectures in a face-to-face classroom, experiential learning assignments and reading assignments. About 50% of the grade in the course is based on experiential learning activities and the other 50% is from on-line exams based on content in the on-line lectures and reading material.

Design of the Problem-based Learning Unit and Assessment

In the unit, students assume the role of a 29 year-old man whose mother died of a genetic disease called Huntington's disease. The ultimate objective of the activity is to make a decision about whether the man should undergo pre-symptomatic DNA testing for the genetic disease.

Two versions of the PBL unit were tested. Version 1 had three assignments (Defining the Issues, Gathering Information, and Solving the Problem), which served as guiding problems for the unit. All of the assignments were done as cooperative learning activities involving groups of 2 or 3 students.

A problem with the first version of the PBL unit was the narrow focus on just one genetic disease. Because of this the unit was revised by replacing the Gathering Information assignment with two other assignments, Genetic Diseases and Genetic Testing, which gave the students a broader view of the subject. The other two assignments, Defining the Issues and Solving the Problem, were used unchanged in Version 2 of the PBL unit.
Evaluation of the Problem-based Learning Unit

Students using PBL Version 1 took a non-credit pre-module exam containing questions from the same test bank (thus, the same difficulty) as the for-credit post-module exam. Results indicated that students experienced a significant gain in factual knowledge about genetic testing during the unit.

We also compared student performance on the post-module exam with the performance of students who took the course prior to developing the PBL unit. The Genetic Diseases module was initially taught using an instructor-centered approach. The exam scores for students taking either version of the PBL unit were not significantly different from those of students taking the module in the instructor-centered mode (pre-PBL). This suggests that teaching the module in a problem-based mode does not compromise the acquisition of factual knowledge.

Average grades for the Genetic Diseases, Genetic Testing and Solving the Problem assignments were 90%, 91% and 92%, respectively. This indicates that significant higher order processing of the fact-based information was occurring.

Student evaluations of the PBL unit were positive when asked to evaluate the accomplishment of learning objectives. Student attitudes toward the two PBL versions were similar in both quantitative and qualitative measures. The cooperative learning aspect of the PBL offered students experience in time management, schedule coordination, and division of labor. However, some students expressed concerns about scheduling difficulties for synchronous electronic meetings with their cooperative groups, and the technical difficulties inherent in an on-line setting (such as Internet lag, computer crashes, or bandwidth or browser problems). In addition, group activities decrease some of the temporal and geographic flexibility advantages that asynchronous on-line courses offer.

Conclusions

Learning objectives in PBL situations include the development of critical thinking skills, professional competency, problem-solving abilities, the acquisition of knowledge, the ability to work productively as a team member, and the acquisition of skills supporting life-long learning (Albanese and Mitchell, 1993; Ryan and Quinn, 1994). The assignments and exams for the PBL were designed to evaluate the achievement of the first four of these objectives, while student evaluations allowed us to evaluate the achievement of the final two. The reports by the student groups indicate a high level of internalization, synthesis, and discursive construction of knowledge, integrating their learning of material from this course with their individual background and experiences, fused to a common consensus within the student groups. Evaluation of exam scores indicates that significant factual knowledge is acquired through the PBL format. While PBL did not increase factual learning over the non-PBL format, it did not appear to negatively compromise factual learning, either. Student evaluations of this unit indicated that the final two objectives were met in a realistic fashion. Although students did note a few difficulties with the PBL format in the on-line setting, we feel with student performance on this unit that the advantages of the cooperative PBL format balance the disadvantages experienced by certain students and student groups. Our experience indicates that PBL is a valid means of expanding student learning in on-line classes.

The Design of a Web-Based Calculus Learning Environment

Ching Hui Alice Chen, Achen@mcu.edu.tw
Department of Computer and Communication Engineering
Mei-Chen Chu, mcchu@mcu.edu.tw
Yu-Hua Pai, yhpai@mcu.edu.tw
Department of Information Management
Chia-Hui Ho, chho@mcu.edu.tw
Department of Computer Engineering
Ming Chuan University
Taipei, Taiwan.

Background

For most students in the department of Information Management, “calculus” has always been one of the most difficult courses to study. The largest part of reason for their problems results in their previous educational experiences. For the past educational system in Taiwan, students have to pass the entry exam in order to enter colleges. Therefore, students know how to take tests without understanding the underlying concepts of the test items. Although calculus teachers often use visual aids to demonstrate concepts, students usually do not have the ability or enough information to understand. As a result, more and more students fail calculus course, and have to take it repeatedly. It has always been the major concern for the calculus teachers to find a way to solve the problem.

Web-based learning environments have been the main trend for education in the last few years. The unique function of web-based learning environment provides teachers a space to upload their teaching materials, a location to interact with individual student, and to trace students’ learning progress without time constraint. Web-based learning environment also offers students the opportunity to interact with others, to review learning materials whenever they needed, and to share their thoughts with fellow students and teacher. Due to the promising multimedia and web technology, calculus teachers will be able to demonstrate abstract concepts in an understandable manner, to provide step by step guiding on how to solve calculus problems, and to monitor students’ problem solving pattern in problem solving activities.

The purpose of this study is to design a web-based calculus learning environment to supplement the traditional classroom teaching, and to examine the effectiveness of this web-enhanced learning environment on calculus learning. It is hoped that through detailed investigation, this study will contribute additional information to the design of web-based learning environment, and provide guideline for teachers and instructional designers to construct better environment for procedure knowledge learning.

Theoretical Framework

In the learning process, failures to access and use potentially relevant information result in failure to transfer (Bransford, et al., 1990). A few studies suggested that when information is introduced in a problem-solving context, it is more likely to be used in new context (Adams, et al., 1988; Lockhart, Lamon, & Gick, 1988; Perkins & Salomon, 1989). Many research have found that working on projects or problems is an engaging activity with potential for facilitating learning (Blumenfeld et al., 1991; Katz, 1994; Moursund, 1999).

Constructivist theories support the development of open-ended learning environments, and tend to favor problem-solving activities that are linked to student interests, that have some attributes of real-world problems, and that are meaningful and satisfying for students to solve. From the constructivist perspective, interest is the fuel of the constructive process. Without interest, the learners will never make the constructive effort to make sense out of experience (DeVries, 1993). Learning should be an active, constructive process whereby learners generate meaning for information by accessing and applying existing knowledge (Jonassen, 1988). The majority of learning theories guiding web-based instruction are based on the constructivist principles.

The design of web-based instruction should integrate the constructivist principles, instructional implications and the Web features, such as hyperlink, multimedia, and synchronous and asynchronous communication (Khan, 1997). Hyperlink structure enables learners to build their own representation of knowledge, and control content sequencing. Multimedia material provides a variety of presentation of learning materials. Different modes of communication support collaboration learning that enables learners to construct knowledge (Miller, & Miller, 2000). How to design a web-based learning environment that presents learning materials meaningfully, that provides authentic problem-solving activities, that implements the unique web technology in the learning activities, that offers teachers and students a space to convey information and construct knowledge is a big challenge for educators and instructional designers.
Web-Enhanced Learning Environment

The content of the web-enhanced learning environment focused on the differential calculus. There are seven sections in the web environment:

1. Learning Material Bank:
   This section uses hypertext and multimedia to present information and to demonstrate concepts. Due to the nature of the calculus concepts, many animation clips were designed to provide additional information channels on problem solving process. Real-world situations were connected to more difficult and abstract concepts that were demonstrated by interactive multimedia segments.

2. Test Bank:
   This test-item database provides three different levels of test items. Based on their ability, students can select the appropriate level of tests to evaluate their understanding on learning materials. After the test, the program will provide a test report that will indicate the test items missed by the students. This report also has hyperlink linking the missed test item to the relevant learning section. This test bank can also be used as on-line tests during the class.

3. Guided-problem-solving section:
   This section, based on the scaffolding principles, provides step-by-step guiding in solving problems. The problems presented in this section are also related to students' daily life experience. Students can solve problems directly or choose guiding whenever they encounter problems.

4. Problem-based learning section:
   This section requires cooperative learning in groups. The problems are real world situations that involve students in problem-solving, decision making, give students the opportunity to work autonomously over extended periods of time with group members; and to present the solutions. Students can use e-mail or chat room or discussion center to communicate and interact with each other. All the discussion and problem solving process will be stored as log file for further investigation.

5. Mathematical place:
   The history of mathematics, mathematicians and web links are presented in this section, giving students additional knowledge on mathematics.

6. Record tracking:
   Students’ learning paths, test record, and discussion will be stored in the tracking database. Teachers will be able to track down individual student, or groups to monitor their learning progress.

7. Idea sharing:
   Students use this section to share their ideas, thoughts, or new problem-solving skills with other students and teacher, and to express their feeling about the course or learning materials. It also gives teachers the opportunity to understand students' thinking and comprehension of the course.

The effectiveness of this learning environment will be evaluated in the next school year.

Introduction. In this paper, we propose using aglets, a specific type of Java-based mobile agents, to enhance distance education. The Internet has become a ubiquitous environment for students, researchers, and educators to share resources, exchange information, distribute reports, and collect data since the creation of the World Wide Web (WWW). Among the many factors that have contributed to the unquestionable success of the Internet, the wide availability and ease of use of computer software programs have played an important role, in addition to the increasing bandwidth of the communication networks. Most of the software programs currently in use on the Internet, however, are either stationary or reactive, meaning that during the execution of a task the code stays in a given host until the task is completed. Although the code of the agent can be transported from one host to another, it is transferred without carrying any state. On the other hand, mobile agents are software programs that can be instructed to halt its execution on a given host, travel with the current state to other participating hosts across a network and continue execution there. They can also be retracted back to its original host if necessary. Mobile agents offer certain capabilities that are not readily available with stationary agents.

What Are Aglets. An aglet is a software agent implemented with Java using the IBM Aglets Workbench, developed at the IBM Tokyo Research Laboratory [LaOs98, URL01]. The term aglet is really a combination of two words: agent and applet. An agent is in general referred to as an autonomous software program that acts as a representative of some user, and an applet is a Java class (a piece of Java code) that can be transported, at the user’s request, from a web server to a web client and then executes on the client machine as a thread within a browser. Although aglets can be stationary, the main objective of the Aglets Workbench is to allow users to develop mobile agents and the majority of aglets are indeed mobile agents. For this reason, aglets are often referred to as Java-based mobile agents. Aglets have three important properties: behavior, state, and location. They differ from applets in that applets, once downloaded and instantiated, begin execution in the client machine until all specified tasks are completed, while aglets can travel (either reactively or proactively) with their current state from a participating host to another participating host across a network, including possibly returning to its origin and distribute their tasks among all the hosts in the itinerary. Aglets also differ from servlets in that the latter are uploaded from a client, or from some host in the network, to a Java-enabled web server and get executed in the server during their entire lifetime. The relationship between a web browser and a web server is basically a client-server model. Each running aglet server, however, is a peer-to-peer process.

Specific Aglets for Educational Enhancement. There are many good reasons for using mobile agents. Seven of them are presented in [LaOs99], including the potential for reducing network traffic and overcoming network latency, the ability to encapsulate protocols, execute asynchronously, and adapt dynamically, and the capability of lending themselves to heterogeneous, robust, and fault-tolerant processing. Since aglets in general mobile agents, they enjoy most of the benefits that can be offered by mobile agents. It should be mentioned, however, that very few problems, if any, that can be handled using aglets cannot be solved using traditional stationary agents or mobile code such as applets and servlets. The question of which type of software should be used certainly depends on several factors: the nature of the application, the latency of the network, the connectivity of the host, the relative size of code transfer vs. data transfer, and the frequency of such transfer, just to name a few. Mobile aglets have many applications on the Internet [KiZi97, KoGr99]. In the following, we briefly describe some specific aglets that need to be developed in order to achieve our goal to enhance distance

* The first author was supported in part by the Army Research Laboratory under grant DAAL01-98-2-0065
education. These include a message broadcast aglet, homework assignment distribution aglet, homework assignment collection aglet, grade report aglet, progress monitoring aglet, file transfer aglet, and communication aglet with textual, graphical, audio and video support.

The message broadcast aglet is for the instructor to deliver notices, announcements, and/or other urgent messages to all students simultaneously in a timely fashion, one aglet for each student. Upon receiving such an aglet, the student should respond to the aglet indicating the receipt of such a message. This aglet then carries the response back to its originating host and stores the response information in a log file to let the instructor know if all students have received such a message. The homework assignment distribution aglet works in a way similar to the message broadcast aglet, except that the aglet carries the assignment to the student’s host in a form of files and store the assignment to a file or files. The announcement of the assignment can be sent using the message broadcast aglet at any convenient time. The homework assignment collection aglet is sent to the student’s host to automatically collect the assignment conducted by the student when the assignment is due, instead of asking the student to submit their assignments to some specified server. One way of making this automatic collection possible is to specify the use of a unified filename. In other words, all students should perform their work or store their finished work in a file and use the same filename for a given assignment. At the instructor’s host, a directory can be created for each student and for each assignment. This directory is used to store the work collected from the student. The communication aglet is for message exchanges among students and between students and the instructor. To initiate communications, the user must have one of such aglets ready for use at his/her own host. It is not required, however, that the responding party pre install that aglet beforehand since the aglet that initiates the communication can carry the necessary functionality to the other party. Therefore, each student can have his/her own favorite communication aglet, if one available to them. This is an obvious advantage over the current communication systems such as NetMeeting, ICQ, or Messenger because the use of them requires pre-installation of the same software by each participating user before a conversation can begin. The tradeoff here is the initial transfer of the aglet itself over the network at each initiation of the conversation. A prototype communication aglet that allows for textual and handwriting message exchanges has been developed in [ChTu01]. In addition to the aglets mentioned above, a grade report aglet and a progress monitor aglet can also be designed to allow students to obtain their grades at the end of the semester and to allow the instructor to monitor the progress of the student during each homework assignment, respectively.

Conclusion. The Internet has become a ubiquitous environment for resource sharing, data collection, data distribution, information exchange, and global communications nowadays. Most of the software agents currently in use on the Internet, however, are stationary. In this paper, we proposed using aglets to enhance distance learning and administration. Several specific aglets for educational use have been addressed. These aglets offer certain capabilities that are not readily available with stationary agents.

South China Normal University
GuangZhou, China
pinde@snu.edu.cn likd@snu.edu.cn

Abstract: Web-based education systems are becoming increasingly popular in recent years; however, most of the systems developed so far use static hypermedia as the manner of representing contents. It's a challenge to develop advanced Web-based education applications that can offer both adaptivity and intelligence. This paper will review some related works in this area and present a design of advanced Web based learning system that support adaptive presentation, adaptive navigation and adaptive help.

Keywords: adaptive hypermedia, adaptive presentation, adaptive navigation, adaptive help, User Model

1 Introduction

Advantages of web-based education systems which are becoming increasingly popular in recent years have been discussed in many papers. Learning resources are becoming unprecedented abundance in the web. This is just the start and the trend is going to last for a long time.

In spite of all the popularities, the uses of web-base educational applications are still at a very low level. According to the authors of [1], web-based education systems can be classified into three levels: Base level, State-of-the-art level and Research level. The majority of education systems currently being used are either base level or State-of-the-art level; multimedia resources, structured contents and multiple navigating ways are the distinct features of these systems. In these systems, however, contents are presented using static hypermedia. The advanced web-based educational systems, which are in research level, inherit some merits from intelligent tutoring system (ITS), hypermedia system and adaptive system. Their distinct features are adaptivity and intelligence. In this article, we refer the former as the first generation web-based education systems and the later as the next generation systems. In fact, researches on web-based instruction theory, instruction model and advanced instruction tools or platforms lagged the progress of the Internet technologies.

Most of web-based education systems in research level have not yet found their way to real-world virtual classroom. There are only a few being used in relatively small classes. There have been many researchers actively involved in this challenging area since 1996. In [2], adaptive and intelligent technologies applied in Web-based education systems were reviewed and grouped by its origin as follows.

- ITS technologies in Web-based education curriculum sequencing, problem solving support technologies.
- Adaptive hypermedia technologies in web-based education: adaptive presentation and adaptive navigation support.
- Web-inspired technologies in Web-based education: these technologies had little use in educational systems before the Internet age. In [2], such technology is called student model matching because the essence of this technology is the ability to analyze and match student models among many students at the same time. Two examples of student model matching were identified, which were called adaptive collaboration support and intelligent class monitoring.

Intelligent problem solving support technologies use AI extensively. These technologies are closely related to application domains and are difficult to generalize, thus they will stay on research level for a long time. On the other hand, adaptive presentation, adaptive navigation support and model matching technologies are relatively easy to implement in web, and general authoring tools can be developed and deployed in large mount of education systems.

This paper is organized as follows: Section 2 gives a brief review of previous researches on adaptive
presentation, adaptive navigation support and model matching in web-based education systems. Section 3 introduces some function zones in web-base course pages. Section 4 describes the design procedure of web-based course which utilize the above technologies. These procedures can be generalized and be made into software tools used in all web-based courses.

2 Quick Review of Related Work

The first comprehensive review on adaptive hypermedia system can be found in [3]. In [4],[5], the author continued tracing research progress in this area. In [3], Brusilovsky distinguished two adaptive methods in hypermedia systems: adaptive presentation and adaptive navigation support.

The following techniques for adaptive presentation were mentioned:
- Conditional text
- Stretch text
- Fragment variants
- Page variants
- Frame-based techniques

The techniques for adaptive navigation support listed in [Brusilovsky 1996] [De Bra 1998] are as follows:
- Direct guidance
- Link sorting
- Link hiding, link disabling, link removal
- Link annotation
- Map adaptation (provide personalized overview)

Most of adaptive hypermedia are education hypermedia, such as [6],[7],[8],[9],[10], which demonstrate some of the technologies mentioned above.

Research on general model of AHS and its formal descriptions can be found in [11],[12]. In [11]], An adaptive hypermedia application is defined as a 4-tuple <DM, UM, TM, AE> where DM is a domain model, UM is a User Model, TM is a teaching model, and AE is an adaptive engine.

Some AHS authoring tools such as Interbook [13], AHA[14] and NetCoach[15] have been developed in recent years. InterBook is a tool for authoring and delivering adaptive electronic textbooks on the World Wide Web. The main feature of InterBookis that it provides a technology for developing electronic textbooks from a plain text to a specially annotated HTML. AHA is an open Adaptive Hypermedia Architecture whose core is an engine that maintains a user-model based on knowledge about concepts. The content of a page can be adapted by means of fragment variants. The links are annotated by changing the color of the link anchor. NetCoach is designed to enable authors to develop adaptive learning courses without programming knowledge. It provides web-based tools for the teacher to author course structure, exercises and to customize user interface.

As for adaptive collaboration support, an example in this area can be found in [16]. This paper reported an Intelligent Helpdesk system which integrated two cognitive tools: CPR (Cooperative Peer Response)[17] and Phelps(Peer Help System). The former is a discussion forum collaboration tool that is customizable to a particular course, providing peer help and FAQ facilities via the web. Every entry in the discussion forum and FAQ were indexed by a class-specific category or topic. Phelps supports student as they are learning, offers assistance in finding peer helpers by model matching when required, and mediates communication on related topics.

In this paper we will analyze learning environment in web-based course systematically, then propose a design scheme, which integrate adaptive content and adaptive help.

3 Function zones in web-based course

In perspective of function, a page in the most of web-based course can be divided into three zones:
- Function zone: most of learning tools are shown in this zone. It looks like menu or tool bar in application software. The content in this area is almost the same in all pages of this course.
- Navigation zone: it helps users to learn about the structure of the web-based course or to guide them through it. Usually it consists of structuring index table and some navigation buttons.
• Content zone: It comprises material (content, examples, exercises etc.), which is main part of a page. Some navigation buttons are also included.

These zones are separate in frames, and every zone is an independent html file. They can also appear in a single html file with table to separate them.

In the above adaptive hypermedia, the adaptivity is mainly embodied in navigation zone and content zone. For example, in Interbook, adaptive navigation support lies in annotation in index table and direct guidance button in content zone. In AHA, adaptive presentation is shown in content zone hyperlinks in content zone also included.

Besides, we should see that tools in function zone are important parts of the web-based course environment. These tools can be content table, search tool, bookmark, help tool, communication tool, etc. Actually, many other tools can be easily added to the function zone. Most of them are independent and can be designed and implemented individually. When needed, they can be linked into function zone. So, in this paper, we will not discuss design of such tools. What we concerned is only adaptive help tools that share the same User Model and domain model with adaptive hypermedia.

4 Designs.

Our schema is a user-model centered integrated learning system feature adaptive presentation, adaptive navigation support and adaptive help. When a course is delivered via the net, the system structure can be shown as Fig.1.

The following are design steps of an online course for a teacher:

1. Extract set of concepts (SCs) from the given domain; set of goals (SGs) and set of background knowledge (SB) are also specified by the teacher.

2. Design curriculum structure. Usually, each curriculum is divided into chapters, sections and points of knowledge; these elements are grouped in a tree structure. Each node of the tree has a corresponding page. These pages are called “virtual pages (VPs)” since they are not real html files, but only comprise structure description of a page.

3. Construct knowledge fragments (KFs). They can be done using web page authoring tools. These fragments can contain all kinds of media as well as hyperlinks. They can be explanations of concepts or examples; each concept can be presented by different explanations and different
examples. Every fragment has a set of attributes (concept, role, object etc.).

4. Virtual Page (VP) consists of knowledge fragments (KFs). In order to make these pages show different contents to different user, construction rules must be applied to these pages. These rules will make sure that different user with different background or different learning goal will see different contents.

5. Each virtual page will have its own sets of prerequisite concepts and output concepts. This information will be used to implement adaptive annotation and direct navigation.

6. There will be one set of tests (STs) for each of the virtual page. These tests will be used to analyze the mastering state of users on these concepts.

The data parts of web based learning system are made up of SCs, SGs/SB, VPs, KFs, STs and User Model. User Model consists of user's knowledge level, learning goals as well as their background. User's knowledge level is an overlay model. For each domain model concept, an individual overlay model stores some value which is an estimation of the user knowledge level of this concept. This can be just a binary value (known-not known), a qualitative measure (good-average-poor), or a quantitative measure, such as a probability that the user knows the concept. An overlay model of user knowledge can be represented as a set of pairs “concept-value”, one pair for each domain concept[3].

An adaptive engine will be used to generate web page dynamically based on values in the User Model and other data listed above when the curriculum is delivered via web; the pages demonstrate the features of adaptive content and adaptive navigation. When a user access a virtual page (VP), an adaptive engine will act as following:

Generation of content zone:
1. Generate contents of page (P1): Content of a page consists of KFs. The ways to combine these KFs are decided by page construction rule. Goal value and background in User Model will be used as rule is executed.

2. Analyze hyperlinks in P1; generate a new page (P2) using appropriate annotation. Knowledge level in the User Model will be used in this step to decide how hyperlinks are displayed. For example, if a user is not prepared to visit a page, the link for that page will be hidden or marked in red color; Links to mastered contents will be gray out; Links to accessible pages will be displayed in green.

Generation of navigation zone:
Every page in VPs has a set of prerequisite concepts and output concepts; this makes it easy to mark the index table of curriculum contents separately based on the knowledge level in User Model. User can set the way of marking index table. Index table can be marked in different colors or different icons. It's a good practice to keep the style of index table annotation in line with the marking of hyperlinks in the content zone. The button for next step (direct navigation indicator) can be generated based on information in the User Mode, also.

The final page a user can see is generated after the processing of all information mentioned above.

Maintenances of User Model

The User Model can be maintained based on the way user browsing the pages (including pause time) as well as scores of tests on these contents. The later will be reliable source for judging user's mastering of related concept.

Adaptive help

Information of this kind of Domain Model and User Model can be used to generate adaptive help as well as make class contents and navigation adaptive. Help system is a tool which resides in the function zone (on a page). The help system is a discussion forum; each topic of the forum is indexed by concepts in Domain Model. When user wants to submit a question, the user must select one or more concepts (from the list). The system can use the user input to make sure that all FAQ and contents of discussion forum are correspond to the (user selected) concepts. This approach makes help system more adaptive. When a user click the help button while viewing a page, the help system will act as following:

The system know the page from which the help is required, and then it will know the concepts referred to on that page. The system can generate a help page based on that information.
The indexes of prerequisite knowledge for these concepts are displayed on top of the generated help page. User can visit that prerequisite knowledge by clicking those links.

Answers to questions on the concepts are also displayed on the help page. These answers are extracted from FAQ and discussion forum.

User can resubmit question if the desired help information is not found on the returned page.

Help information from this help system is generated according to the position of current question as well as knowledge level of the User Model. The system utilizes entries indexed by concepts of Domain Model and User Model to generate personalized help information.

Based on what we presented above, there are a lot of works need to be done to design Web based adaptive learning systems. Our goal is to design a set of tools that can be used by teachers to fulfill all those steps mentioned above. These tools include:

- Tools of define domain concepts, learning goal and background knowledge
- Tools of define class structure
- Tools of define rules of page construction
- Tools of define prerequisite concepts and output concepts
- Tools of create exercises
- Adaptive engine
- Help engine
- Discussion group on indexes for domain concepts

The procedures and tools mentioned above are general purpose, they can be used on all kind of online course design and implementation.

5 Progress of the work

There have being more than thirty online universities in China, and thousands of curriculums are offered on line. There are more than fifty online curriculums being constructed in our university. The purpose of our work is to formalize the creation of online curriculums and to improve online education to a higher level. The distinguish feature of our system is adaptive and adaptable. Our work is still in the early phase; we believe that our work will be beneficial to distance education.

1. Introduction

In 21st century, information and knowledge are the motive power changing our society and the foundation of our country's competitive power. Information-using ability becomes a criterion to decide the competitive power, and the quality of knowledge and information which human and society possess determines the quality of human life. Accordingly, the Ministry of Education and Human resources development decided on the use of ICT (Information and Communication Technology) in education for students to obtain and practically use the fundamental knowledge about information making, processing, treating, analyzing, exploring, etc. Therefore, the Ministry encouraged every school to use 10% of class time at least to teach the knowledge about information in an instruction & learning procedure. Consequently, schools try to reform the classes according to the request of the Ministry and it produces a change of educational environment. As one of these efforts, various instruction-learning procedure ideas are being developed in schools at present.

Many contents about education are constructed with web-based type, but the lesson plans have been written out with Word-processor. The Ministry recommends teachers to make a lesson plan using a Powerpoint. It is true that many lesson plans have been made and uploaded with board-type, so they are not saved in database in accord with educational curriculum. For these reasons, in this study, teaching-learning plans were designed as a form using ICT in education and developed as web-based electronic teaching-learning unit system that is available to prepare and use in web.

The contents and methods are following: First, the electronic teaching-learning unit using ICT was designed based on the existing various types of plans. Second, the system which teachers can form the teaching-learning plans in a web-based online situation was reflected to the total construction of this system. Third, according to the 7th educational curriculum and the type of the teaching-learning plans using ICT, the database system was developed for an effective use of ICT materials when one draws out the procedure plans with an electronic teaching-learning unit system. Finally, new electronic teaching-learning unit system was applied in real school fields and through the questionnaire analyses, the effects and improving points of this system were found.

2. Web-based Electronic Teaching-Learning Unit Systems

Design

The whole structure of the electronic teaching-learning unit system was constructed as database to make out the lesson plan and a module to manage the completed lesson plans. The database for making a lesson plan was designed as 3 parts, curriculum DB, ICT lesson plan DB and ICT materials DB. Organically related 3 Databases composed of RDBMS. A Client is managed by dividing the electronic teaching-learning unit system and a storehouse of ICT materials and these 2 systems are managed with organic relationship.

[Figure 1] System architecture

Implementation
To realize this system, Linux server and MySQL were used and in a system driving method, PHP and JAVA script were utilized based on HTML. This shows that many useful programs can be made with GNU Software suggested by GNU Project and utilized in real fields. The system is composed of the ICT electronic teaching-learning unit system and a storehouse of ICT materials. The first screen is following. The teaching-learning unit system and the storehouse system have an interactive and cooperative relationship.

![Figure 2] ICT electronic teaching plan  ![Figure 3] ICT materials

The completed lesson plan using this system is like below. The special point of this teaching plan is to make out a lesson plan on the web easily and that there is a list of ICT materials that are supposed to use during the class. These multi-media materials are linked so that teachers can make use of directly. In addition, all materials linked in a lesson plan are stored in database, so they can use only materials and it is easy to share and search them.

![Figure 4] Example of completed ICT electronic teaching plan

3. Advantages
Some elementary school teachers living in Inchon, Korea actually used this electronic teaching unit system to make out their lesson plans. After using this system in the class time, most of teachers showed positive responses.

The result of application of this system is as follows.

The effect of making electronic teaching-learning plan
1) Web-based system of the electronic teaching-learning plan improved convenience to make the lesson plan through making database of current educational curriculum of an elementary school
2) Making the lesson plan and using ICT materials by using this electronic teaching-learning unit system are much easier than by using a word-processor or powerpoint. The system maximized the variety and utilization of ICT materials necessary to make a lesson plan
3) As all teachers made out the lesson plans by themselves using the electronic teaching-learning unit system, ICT application ability in education was improved and a lesson model using ICT was established
The effect of utilizing electronic teaching-learning unit system.
1) The electronic lesson plan is stored at database in server, so it makes possible to accumulate different types of ICT using lesson plans though they are same lesson. Additionally, it makes available to explore ICT-using lesson plans according to the keyword, chapter and the ICT-using type.
2) By considering both circumstances of teachers' study of teaching aids and actual lesson situation, they can select either 'watching the lesson plan' or 'doing lesson' modes when they use electronic teaching-learning unit system.
3) It is a good try for "Doing lesson" but it needs improvement of interface.

The effect of contents library
1) It is possible to link and upload the various ICT materials and it can accumulate the huge amount of ICT materials.
2) ICT referential materials are not fixed but every new material is added automatically. So, lesson plans and a storehouse of materials were interactively related to make this system.

4. Discussions
The followings are some suggestions for the growth of this system that was developed for activation of ICT-using education in Korea:
1) This system will be shared by many schools so that more lesson plans can be provided as well as continuously be updated new lesson plans.
2) This system will be modified for teachers to change the procedure steps from 3 fixed steps, introduction, development and adjustment into more 3 steps as well as the names of steps according to the characteristics of each subject.
3) When the actual lessons proceed, teachers will be able to choose the time that they want to show ICT materials; therefore they will designate the time in "Doing lesson" module of this system when they make out the lesson plan.
4) By using FLASH not the JAVA SCRIPT for a tool of making a "Doing lesson" module, more polished interfaces will be needed and the "Doing lesson" module will have not one frame but different and various frames of module according to each subject.
5) This system will be modified in English and become a package to use in education practically.

5. Conclusion
Developed web-based system of an electronic teaching-learning unit is practically used in school fields now. It is worth an alternative proposal of the PowerPoint-type plans that the Ministry suggests. The results after the application of this system are following.
Web-based system of an electronic teaching-learning unit is designed to use database in web considering accumulation and use of the data and convenience. It is managed through database not only all learning of 7th educational curriculum, but also ICT materials which are the most necessary to the class, so it is convenient to control the procedure plans easily.
To form the procedure plans easily for users, a module was devised and to make a continually developing system, the materials and the teaching-learning units were organically connected. The development of this system realized the maximization of the teaching-learning plans' share, practical use and storage. In addition, it will be generalized in real school fields and contribute the informatization of school.

Abstract: With the advance in Internet technology, "e-learning" becomes an active research topic. To make e-learning an effective learning mode, both technology and pedagogy are equally important. However, existing e-learning platforms and tools usually focus on the technology aspect without much investigation on the pedagogical issues. In fact, there is still a big gap between pedagogy and technology. The SPACE Online Universal Learning (SOUL) platform is designed to fill this gap and provide an effective e-Learning platform for e-course providers. In particular, the content engineering agent of the platform is designed for e-course development, which is based on the Task-Based Learning (TBL) curriculum development framework. In this paper, we discuss the details of this content engineering agent with the main focus on the Task-Based Learning framework. As a remark, the content engineering agent has already been integrated in the SOUL platform, which is being used by more than 17,000 students.

1. Introduction

With the growth in Internet and the advance in Internet technology, "e-learning" provides an alternative learning model for teachers and students other than traditional classroom teaching and distance learning. And Clearing has become the focus of research by education professionals (Leadbeater, 1999). A lot of e-learning platforms, such as BlackBoard (Blackboard, 2002) and (WebCT, 2002), have been developed by different researchers and vendors (see also Gertner & VanLehn, 2000, Zhou et al, 1996). However, these existing platforms usually focus on the technology aspect without paying much attention to other issues such as pedagogical concerns and quality control. These issues are, in fact, critical in the success of e-learning (Harasim, 1999, Furnell et al, 2001). The following summarizes some of the drawbacks of the existing platforms:

- Big gap between technology and teaching pedagogy: Existing platforms seldom emphasize on this aspect. Consequently, the lack of pedagogy makes these platforms perform like repositories of course materials. They just allow students to retrieve materials from the platform. As a result, they are still far away from traditional face-to-face teaching, not to mention replacing it in the near future.
- Quality control: Existing platforms usually do not have quality control in e-course curriculum development and have poor feedback mechanism to evaluate the effectiveness of the course materials.
- Poor personalization: Truly personalization of individual student's learning path based on individual's studying pace and knowledge background is not implemented in existing platforms. Specific advice for individual students regarding personal learning problems are missing.
- User-friendliness (usability): Teachers are required to take a long time to learn to use the platform and usually a team of technical support staff is necessary for ensuring smooth operations performed by the teachers. And communicating the instructional requirements between teachers and technical teams is the bottleneck of e-course development provided the communication is possible at all.

In order to address these issues, the School of Professional and Continuing Education (SPACE) of the University of Hong Kong set up a team, called the SPACE Online Universal Learning (SOUL) Project team, in 1998. The
aim of the project is to provide online support for educational purposes; to develop SPACE online support courses in both Hong Kong and the Mainland China; and to carry out researches related to online learning. The SOUL platform is the major product of the project group.

The SOUL platform is based on the system architecture, called the PowerEdBuilder, which will be described in the next section. Different components of PowerEdBuilder will tackle different issues regarding online learning and will work together as a single platform to provide a comfortable and user-friendly environment to teachers, students and administrators. In particular, the Content Engineering Agent together with the Smart Tutor component, of the PowerEdBuilder are designed to provide pedagogical support for teachers to create a course as well as tailor-made personalization for students to learn the material. For descriptions of different components of the PowerEdBuilder, one can refer to the publications of the SOUL project team [7]. In this paper, we will focus on the Content Engineering Agent and describe the Task-based Learning framework of this component.

The rest of the paper is organized as follows. Section 2 provides an overview on the SOUL platform. The details of the Content Engineering Agent, with focus on the Task-based Learning framework, will be given in Section 3. Section 4 will contain the discussion and conclusion.

As a remark, SPACE is one of the leading adult education providers in Hong Kong providing life-long learning for the public. The number of students registered with SPACE programs is more than 60,000 and the number is expected to grow in a tremendous rate. The SOUL platform has already been put in production while improvement and enhancement are being made continuously. Currently, more than 17,000 students and teachers are using the platform. We are collecting feedback from the users in different aspects which will be used to further improve the platform. These evaluation results will be published in another report once available. We hope that our experience can help the community to build a better e-learning environment for students, teachers, and administrators.

2. The SOUL Platform

The SOUL platform, developed by the SOUL project team, is an online learning platform especially for teachers, students, administrators, as well as alumni of SPACE. Although the platform is tailor-made for SPACE users, the design is general and flexible enough to be adopted by other e-learning institutes. The system architecture, called the PowerEdBuilder, of the SOUL platform is shown in Figure 1.

The Secure e-Course exchange (eCX) component provides a secure layer for protecting the copyrighted course materials (Yau et al, 2002). The Communication and Searching Infrastructure (CSI) provides efficient communication channels among administrators, teachers, and students. The Content Engineering Agent (CEA) is mainly used by instructors to create online course materials and launch online courses. The e-Institute is the administration center of the platform. Finally, the e-Learning platform is where students will interact for studying and downloading relevant learning materials. Smart Tutor is one of the major components inside the e-Learning platform (Zhang et al, 2001). Smart Tutor is an intelligent software that can provide guidance to students like a human tutor and is mainly used by students. Expert personalized advice and learning path are given to the student based on student profile maintained. All these functions are the results of application of latest development in the field of artificial intelligent.

Each component in the PowerEdBuilder contains different technologies and is the result from a series of research studies. In this paper, we focus on the Content Engineering Agent and we will mainly describe the Task-based Learning framework of the Agent which helps to fill the gap between the technology and pedagogy.
3. The Content Engineering Agent

Content Engineering Agent is designed to bridge the gap between technology and pedagogy based on a common teaching and learning framework called Task Based Learning (TBL) (Fenstermacher, 1998, Raggatt et al, 1996, Willis, 2000). We will briefly describe the three stages of learning based on the TBL framework in Section 3.1 and show how the Content Engineering Agent incorporate TBL framework in the design in Section 3.2.

3.1 Three Stages of Learning

The Task Based Learning (TBL) framework consists of three stages, namely Pre-task, Task Cycle and Post-task. In our domain, that is, the preparation and development of e-course, pre-task is to define the course aims, the course structure, the relationships among chapters and concepts, and to create the course contents including the Question bank. The task cycle will define the tests and examinations by linking the concepts, course materials, and the question banks, define the weightings of these tests as well as the passing criteria for the task. The actual generation of tests and examinations using the Question bank is done by the Smart Tutor of the e-Learning platform. In the post-task stage, the Content Engineering Agent helps to collect feedback from students and provide analysis of performance of students to teachers in order to identify problems in course materials, students, questions, as well as course structure.

3.2 Details of Content Engineering Agent

Tables 1, 2, and 3 show the summary of activities performed by the Content Engineering Agent as well as the Smart Tutor (for completeness, readers can refer to (Zhang et al, 2001) for details of Smart Tutor) in the pre-task, task cycle, and post-task stage, respectively. Due to the space limitation, we will not give the details of each activity in the pre-task and the task cycle stages, readers can refer to (Cheung & Kwok, 2001) for more information.

</tr>
</tbody>
</table>

Table 2: Activities of Smart Tutor and Content Engineering in Task Cycle Stage
Make decision on whether the learner could proceed

3.3 Advise the learner whether he could proceed

3.1 Refine passing criteria for the course

Evaluate the course in different aspects such as course structure, examination difficulty level etc.

3.2 Provide the following information:
- Questionnaire & Written feedback
- Group statistics on overall students' performance
- Analysis of difficulty level of test, concepts and the failure pattern of students
- Identify problematic clusters in course structure
- Correlation results on the materials, course structure and students' performance

Table 3: Activities of Smart Tutor and Content Engineering in Post-task Stage

The post-task stage generates useful information which enables the Content Engineering Agent to help the teachers to make decisions on how to further improve the e-course. Besides the useful group statistics on overall students' performance and written feedback, the Agent will analyze and correlate the failure patterns of students against the course materials, the course structure, the difficulty level of test questions. As an example, the Agent will identify clusters of problems/concepts using an rule-based inference engine and data mining technique (see Figure 2 for a sample output). The agent will then help teachers to relate concepts, chapters, sessions that might be missing currently.

4. Conclusion

The SOUL platform depicted in this paper is a joint effort from the SOUL project team and e-learning practitioners (teachers, administrators etc.) of the HKU SPACE. In particular, the integration of TBL pedagogy into the Content Engineering Agent provides teachers with a comfortable and user-friendly environment to develop high-quality online courses. The first phase implementation of Content Engineering Agent has been completed. Evaluation on the usefulness and effectiveness of the Agent is being conducted. The evaluation result will be analyzed and used as a guideline for further enhancement of the Agent.

Interested readers can refer to the web site (SOUL, 2002) and other publications of the project group for more information and other technologies used in other components of PowerEdBuilder. We hope that our experience in building these components can help other e-learning researchers.

Abstract
In this contribution animated pedagogical agents are looked at from an instructional design perspective. A 'support-typology' was constructed based on different dimensions on which support can be described and different roles instructional agents can assume. This typology is used to analyze current available pedagogical agents. This analysis indicates that current pedagogical agents are designed to provide support on content and problem solving aspects of the task and that they are capable of adapting their support to learning paths. The review of research on the relation between pedagogical agents and learning indicates that, although only limited research has been done, certain agent characteristics are relevant to take into account in further research on the effect of agents on learning. It can be concluded that pedagogical agents offer opportunities to be grasped in open learning environments.

Introduction
Open learning environments with a high level of learner control have been argued to foster the acquisition of complex problem solving skills (Jonassen, 1997). However, research indicates that students do not optimally use these support tools (e.g., Clarebout, et al., 2000; Land, 2000). It is wondered in this contribution whether pedagogical agents might be able to enhance the optimal use of support devices in open learning environments.

Pedagogical agents are animated characters designed to operate in educational settings for supporting learning. They can provide non-verbal feedback through means of facial expressions and gestures (Johnson, et al., 2000).

Adapting support to the need of individual learners is an important issue in designing learning environment, since providing either too many or too less support may be detrimental for learning (Clark, 1991). In order to explore different ways in which pedagogical agents can adapt support to learning needs and enhance the use of support devices, currently available agents were analyzed, using a 'support' typology. After presenting this typology, the analysis of the pedagogical agents is discussed in the second part. A final part presents an overview of research with respect to pedagogical agents and learning. This part gives insight in the extent pedagogical agents have been proved to be beneficial to learning. The discussion and conclusion summarizes the results of the analysis and tries to provide an answer to the question whether these agents might enable to enhance the optimal use of support devices in open learning environments.

Support typology for pedagogical agents
Elen (1995) proposed a scheme with five dimensions to describe support initiatives: amount, formal object, topical object, delivery system and timing of support. This scheme was adapted and elaborated to construct the support typology for pedagogical agents. The support typology has 6 dimensions that look as follows (see Figure 1):

- **Object of support:** support can be directed to different aspects involved in solving complex problems (see also Hill & Hannafin, 2001): content of the task, problem solving steps, metacognitive strategies and handling the technology.

- **Learner control with respect to support:** open learning environments imply by definition a great deal of learning control (Hannafin, 1995). However, since students seem not always capable of making adequate choices with respect to their learning process (e.g., Large, 1996) and given that reviews on learner control do not reveal a consistent positive effect (see for example Niemic, et al., 1996) this aspect requires further investigation. Pedagogical agents can initiate support delivery, students may request support or decisions about support provision can be shared.

- **Adaptability of support:** learners differ with respect to the amount of support needed, depending on their prior knowledge (Ross, et al., 1980) and other learner characteristics such as aptitude and metacognitive skills (Clark, 1990). However, not only the amount of support might be adapted, also the object of support. Learners might need support on the level of the content of the task or on a more metacognitive level. Change in quantity and object of support can be determined by the agent and / or the learner.

- **Delivery modalities:** Pedagogical agents can entail different delivery modalities, which might affect their effect (Moreno, et al., 2000). Pedagogical agents can communicate verbally or non-verbally. Reeves and Nass (1996)
indicate that students view the interaction with a computer (c.q. pedagogical agent) as a social interaction in which three features are essential, namely: image, voice, and personalized language. Pedagogical agents have by definition an image. Hence, this distinction is not included in the typology. The other two features are. A distinction will be made between pedagogical agents using verbal (text or speech) and / or non-verbal language (head nods, gestures, facial expressions). Pedagogical agents can also communicate in a personal way, engaging in a dialogue, or in a more formal way, through a monologue.

- **Timing of support**: support can be delivered at different moments during the learning process. van Merriënboer (1997) distinguishes between information relevant to recurrent aspects (rules, procedures, prerequisites) and to non-recurrent aspects (system, approaches, heuristics). Support for recurrent aspects should consist of just-in-time information and immediate feedback on the quality of the performance. Support for non-recurrent aspects should consist of both information presented up front and delayed. A pedagogical agent can deliver support either up front, just-in-time or delayed.

- **Support style**: this dimension refers to different roles and modalities instructional agents, in this case pedagogical agents, can assume. Literature suggests six typical roles for instructional agents:
  - supplanting: instructional agents take over the tasks and perform them for the learners. The learners observe the instructional agents (e.g. Salomon, 1994);
  - scaffolding: instructional agents perform those parts of the task that the learners are not yet able to perform independently (e.g., Jonassen, 1996);
  - demonstrating: instructional agents show how a task if performed after which they observe how the learner performs the task (e.g. Merrill, 1994);
  - modeling: instructional agents show how a task is performed while revealing and explaining their reasoning process. They solve a task while they articulate how problems are solved, what strategies are used and what mental models are necessary to understand the task (e.g., Jonassen, 1996);
  - coaching: instructional agents provide hints and feedback, activate learners when they perform the task. Instructional agents observe the learners and provide guidance when they experience difficulties (e.g., Barab & Duffy, 2000), and
  - testing: instructional agents tests the learners’ knowledge about certain aspects of the task in order to guide the learning process (e.g., Martens & Dochy, 1997).

These roles can be characterized by (a combination of) four analytical modalities: executing, showing, explaining and questioning. For instance, if the role of the instructional agents is coaching, support can consist of a combination of explaining and questioning. Executing means that an instructional agent performs the task for the learner. Learners observe the instructional agent but do not perform the task themselves. Showing involves the demonstration of the task by an instructional agent after which the learners perform the task themselves. Explaining involves an instructional agent who clarifies the task while the learner performs it. Questioning means asking questions about the task to the learner.

These different modalities may involve the task or part of it and instructional agents may shift between different roles for different parts of a task.

Analysis of different pedagogical agents

Methodology
To identify current available pedagogical agents, ERIC, PSYCINFO and the Internet (using the Google-search engine) were searched. Reference lists in texts generated through these searches were also used to find more information (snowball-method). This resulted in the agents presented in Table 1. Key words used to find information on these agents were 'pedagogical agent', 'animated agent', 'agent and virtual reality', 'agent and multimedia', 'personal digital agent'. Only agents used in educational setting were selected. Previous reviews of pedagogical agents have been presented by Johnson et al. (2000, 2001). They came to a similar list, although their review was not restricted to agents operating in educational settings and was focussed on the technological aspects of these agents. In the following a short description is provided of the different agents, the actual analysis is presented in Table 1.

Description of the different pedagogical agents

**Adele** (Shaw et al., 1999; Ganeshan, et al. 2000): Adele supports distance learning in the domain of medicine and dentistry. She exists in three different interaction modes. In the advisor mode, she observes the students when performing an action. She interrupts and makes suggestions when there is an inconsistency with the standard practice. In the practice mode, Adele provides advice only on request of the student. A final mode is the examination mode where she provides only an evaluation after the students have finished. Recent developments made Adele more focussed on guiding students in their problem solving process.

**Steve** (Johnson et al., 2000): Steve is an acronym for Soar Training Expert for Virtual Environments. He demonstrates 'skills' involved in a specific task. The student can walk around in the environment while Steve demonstrates part of the tasks and explains what he is actually doing (modeling). The student can interrupt the agent and ask to finish the task.

**Herman the Bug** (Lester, et al., 1999a): Herman is an alien with human-like movements and facial expressions. He inhabits a learning environment called 'design-a-plant' for the domain of botanical anatomy and physiology. Herman gives advice, encourages students and provides feedback.

**Cosmo** (Lester, et al., 1999b): Cosmo inhabits the Internet Advisor learning environment for the domain of Internet packet routing. Cosmo provides advice to learners and explains content and problem solving related issues.

**WhizLow** (Johnson et al., 2000; Grégoire, et al., 1999): WhizLow inhabits CPU City, a three dimensional learning environment representing a motherboard. Students are given programming tasks. WhizLow carries out instructions given by the students and traces misconceptions of students that are corrected by providing advice.

**PPPersona** (André et al., 1999): The PPPersona agent, is an animated agent for presenting on-line instruction. The agent guides learners through web-based materials, he demonstrates the information.

**Jacob** (Evers & Nijholt, 2000): Jacob instructs and assists users performing a task in a virtual environment (e.g. tower of Hanoi). Jacob gives feedback on the user performance and can demonstrate the task if necessary.

**Gandalf** (Cassell, & Thorisson, 1999): Gandalf is an expert in the solar system and the user can ask him questions about specific planets. Gandalf will virtually travel to these planets when a question is asked and give an explanation when the student asks for it.

**Autotutor** (Graesser, et al., 1999): Autotutor is designed to assist college students in learning the fundamentals of hardware, operating systems and the Internet. Autotutor presents questions to the students to test their knowledge.

In Table 1 the analysis of these different agents is presented following the support typology.

The analysis reveals different aspects:
Research results

The analysis of pedagogical agents reveals that agents are already used in learning environments to support learning. In this part an overview is presented of empirical research about the relationship between learning and pedagogical agents. Lester, et al. (1997) performed a study to measure agents' affective effects on learning. Five 'clones' of Herman the bug were studied: 1) a fully expressive one, giving principle-based animated advice as well as task-specific audio-advice, 2) one who gave only principle-based animated advice, 3) a clone who gave principle based but only verbal advice, 4) one giving task-specific verbal advice, and 5) a mute one. All other features remained identical. Results show that all students performed significantly better on the posttest. The smallest and highest increase in performance was for the students in the 'mute' and the fully expressive condition respectively. Results on an assessment questionnaire show significantly higher scores for the personal assessment of the agent (utility of the advice and feedback of the agent). Given also the increase on the post-test for the 'mute' condition, Lester et al. conclude that there exists a persona-effect. The merely presence of an agent increases the scores. This persona-effect however was not found by André et al. (1999), who created two versions of their learning environment, one with PPPersona and one without. Moreno, et al. (2000) compared two groups of students working in a discovery learning environment. One group had a pedagogical agent (Herman the Bug), while the other received text-based information. No significant difference was found for retention. For a transfer test a significant difference was found in favor for the group with the pedagogical agent. This group showed also a greater interest and motivation. In a follow up study Moreno et al. (2000) experimented with pedagogical agents varying on the three features of social interaction mentioned by Reeves and Nass (1996): image, voice, and personalized language. The studies indicated that the condition in which an agent with voice was used instead of text resulted in better results for retention and transfer. The sheer presence of an image of the pedagogical agent had no effect. The kind of communication (dialogue versus monologue) influenced the results for the retention test in favor of the dialogue mode (see also Moreno & Mayer, 2000). In other experiments, Moreno et al. (2001) experimented with the type of image. The image of Herman was compared to a video-based image of a real person. No effects were found for this variable on retention and transfer.

In addition to these quasi-experimental studies two, more informal, evaluation studies can be mentioned. The first one relates to an evaluation of Steve (Johnson, et al., 1998). It suggests that interacting with agents in a virtual environment be perceived as more natural than using conventional text-based tutoring interfaces. The second study deals with Adele (Shaw et al., 1999). Students indicated in a survey to appreciate the support provided by Adele. Moreover, students preferred to hear a rationale only when they asked for it (practice mode). Nevertheless experience suggests that students do not ask for advice when given the choice.

Discussion and conclusion

An analysis was made of current available pedagogical agents. To do this analysis, first a support-typology was constructed. This typology provides a common framework to describe and discuss pedagogical agents. The analysis reveals that most pedagogical agents act as coaches and provide support on the level of the content and problem solving. Most of the pedagogical agents are capable of adapting quantity and object of support to learners' action. It can be concluded that pedagogical agents are capable of adapting support to the needs of the learner by reacting to the learning path followed. However, none of these pedagogical agents provide metacognitive support, while such support has been recognized as important (Hannafin, 1995, Shuell, 1992). This might be explained by the origin of pedagogical agents. Pedagogical agents evolved from research on intelligent tutoring systems (Shaw et al., 1999), which are systems focussing strongly on the acquisition of domain specific knowledge (Shute & Psotka, 1996). These tutoring systems were developed, starting from teaching goals and aiming at how to replace a human tutor by an intelligent tutoring system (Derry & Lajoie, 1993) and mostly work with well-structured problems for which one solution exists. The analysis of pedagogical agents demonstrates that, even now, most agents are used in situations that do not require students to solve complex problems but rather procedural tasks for which an optimal solution exists (e.g. Jacob, PPPersona). So, the answer to the question "where do we stand?" would be that pedagogical agents provide a more sophisticated intelligent tutoring system. However, to develop pedagogical agents able to operate in open learning environments in which students have

1. Most agents are designed to act as a coach. The agent provides hints and feedback while the learner solves a problem. Sometimes demonstration of parts of the task is also included (e.g. Steve).
2. Explaining is most frequently used as a modality, complemented by questioning.
3. For all agents, except for Jacob, the main object of support is the content. Some of the agents also provide support on the level of problem solving. Jacob for example provides only support on the level of problem solving. Steve and Adele also support the use of the environment.
4. All agents are technologically able to communicate both verbally and non-verbally. Most agents use speech. Some use both speech and text. Dialogue as communication is mostly used.
5. Just-in-time support is used frequently.
control over their learning and work on a complex task, a different perspective might be indicated. Rather than starting from a teacher-oriented perspective (how to model a good tutor), a student-oriented perspective might be advocated. Rather than starting from focussing on the acquisition of domain specific knowledge, and representing a complete domain-model, metacognitive processes could be focussed upon to enable students to monitor their own learning process.

Pedagogical agents operating in open learning environments and delivering support on a metacognitive level might encourage learners to make more ample and deliberate use of support in open learning environments. Hill and Hannafin (2001) for example argue that students lack the necessary skills to monitor their learning and to make appropriate choices with respect to support devices in the learning environment.

Research on intelligent tutoring systems focussed on whether these systems were a ‘good’ replacement of a human tutor (e.g., Schofield, et al., 1994), research on pedagogical agent should focus on the influence of these agents on (aspects of) the learning process, considering research findings with respect to agent characteristics (Lester et al., 1997; Moreno et al., 2000) and learner variables (Shaw et al., 1999).

Taking a more learner-oriented perspective into account in the development of pedagogical agents and focussing on supporting students on the level of their metacognitive skills could result in pedagogical agents able to enhance the (optimal) use of available support devices in open learning environments.

Clark, R. E. (1990). *The contributions of cognitive psychology to the design of technology supported powerful learning environments.* California: University of Southern California.

Abstract: Computer-based simulations have the potential to enhance the transfer of learning by providing students with surrogate learning environments. However, the success of simulations to a certain degree depend on their designs. In order to ensure learning, simulations should be constructed based on instructional design principles. As Clark (1985) points out, effective learning depends on the design strategies implemented in a delivery system rather than on the system itself. Although different designers have different perspectives when making design decisions (Goosen, 2001), there are common issues faced by designers at large. Serving to provide recommendations for practitioners who will engage in designing and developing effective educational simulations, this paper surveys examples of simulations, examines design issues concerned with computer-based simulations and synthesizes design guidelines suggested in literature.

Introduction

Designing and developing simulations can be complex and costly, and thus it is crucial to consider thoroughly beforehand if simulations should be used for particular educational purposes. Once it is determined that simulations can help to reach specific learning objectives, to better represent the selected phenomena, and to fit the instructional level of the target students, the next step is to consider the design aspects. Although different designers have different perspectives when making design decisions (Goosen, 2001), there are common issues faced by designers at large. In this paper, major design considerations affecting the nature and the effectiveness of simulations are discussed. The considerations include the advantages of simulations over other instructional alternatives, fidelity levels, and student support.

Simulations vs. Other Instructional Alternatives

Simulations can be used when there is no better alternative method to approach a significant learning objective. Simulations offer opportunities for students to understand phenomena which are otherwise inaccessible because of the costs, dangers, or time constraints involved in reality (Dennis & Kansky, 1984). For example, by participating in a financial management simulation, students learn how to invest money and discover the consequences of their actions in a short time. They do not need to raise fund for the investment, take the risk of losing their capital, nor wait for months or even years to figure out the results.

The advantages of simulations over tutorials and drills include: (a) better transfer of learning, (b) opportunities for active exploration, and (c) motivational appeal (Alessi & Trollip, 1991; de Jong, 1991). Simulations teach skills or knowledge in an environment similar to the real situation to which the skills or knowledge can apply. Moreover, in simulations students can actively explore the content domain and therefore as active participants they become more motivated. Once a simulation is chosen as the appropriate instructional mode, designers need to consider two major aspects of simulation design: fidelity and student support.

Fidelity

Fidelity is concerned with to what degree a simulation replicates reality (Alessi, 1988). Unlike the scientific models in which high fidelity is always desirable, in instructional simulations high fidelity is not always a better choice.
over low fidelity (Levin & Waugh, 1988). Theoretically, the relationship of fidelity and learning should be linear. That is, the closer a simulation is to the situation being simulated, the more learning transfer would occur in reality. However, research findings indicate that high fidelity does not always enhance learning for two reasons: (a) high fidelity demands more memory load and cognitive abilities of students, and (b) instructional techniques which are beneficial to novices usually decrease fidelity (Alessi, 1988). Details of more realistic simulations might distract students' attention or generate memory overload, especially when students are in the initial stages of learning.

Nevertheless, the claim that high fidelity is not always desirable in instructional simulations does not imply that simulation design should aim for low fidelity. Rather, the claim indicates that different levels of fidelity are needed in the design. Furthermore, the fidelity concern is about when and how these fidelity levels should be adjusted. Alessi (1988) suggests that the level should increase appropriately as students progress from novices towards experts. Levin and Waugh (1988) propose that a range of fidelities be provided in a simulation in which a content domain is divided into different sections. These sections can be on the same or different difficulty levels. As students progress, they deal with more sections of the same difficulty level or with more challenging aspects of the domain.

**Student Support**

A simulation must include appropriate support in order to guide students to reach specific learning goals (Steinberg, 1991). Without the support, students are not likely to learn the concepts or principles embedded in the simulation when they freely explore on their own. They might ignore more important aspects intended for them to learn and focus on rather insignificant details. They might not be able to find solution paths and thus the benefit they obtain from the simulation is minimized. Moreover, for a simulation that has high cognitive demands to be effective, appropriate support is a must. Although the support is sometimes offered by an instructor, it can be included in the simulation program itself as well (de Jong, 1991).

Two types of support could be helpful to students: (a) directions about how to interact with the simulation, and (b) guidance about how to learn from the simulation (Steinberg, 1991). For the quantity of support available to students, Levin and Waugh (1988) suggest that the notion of “dynamic support” be applied to simulation design. As students advance from novices towards experts, the amount of support they need decreases. Therefore, the amount of support provided by a simulation program should be varied according to students' instructional levels. In the initial level, the program should offer more extensive support. As the students become more experienced in the content domain of the simulation, the support can be gradually reduced.

**Summary**

Drawing upon research findings and examples of educational simulations, this paper synthesizes simulation design guidelines including fidelity and student support. In contrast to other modes of computer-based instruction (e.g., tutorials and drills), simulation environments are much more complex in terms of design and use. However, well-designed simulations can assuredly minimize the complexity of use and enhance their educational effectiveness. The design considerations can assist designers in planning and constructing simulations that facilitate learning.

The Effect of Elaboration Strategies in a Hypertext Environment on Learning

Wei-Fan Chen
Instructional Systems
The Pennsylvania State University
United States
weifan@psu.edu

Abstract: This study investigated Charles Reigeluth's Elaboration Theory in a hypertext environment. An Elaboration-Theory-Based hypertext was designed to compare with a linear hypertext that does not employ any instructional design theories and principles. Thirty-three college students in a large U.S. university participated in the study. The research results showed statistically significant differences between the control group and the experimental group in terms of students' achievements on learning facts and concepts. Further research agenda is proposed according to the results of item analysis in the test.

Introduction

While creating hypermedia environments is becoming part of the mainstream in the implementation of educational media in most of educational settings, the design and development of hypermedia materials are still heavily based on technical issues or simply designed by intuition (Chen & Dwyer, in press). One of the most referred and applied instructional theories, Charles Reigeluth's Elaboration Theory (ET), is the target of investigation in this study. According to Reigeluth (1987), Elaboration Theory prescribes a macro level of instruction by sequencing information in a simple-to-complex approach. More specifically, the theory prescribes that instruction starts with an epitome that teaches a few simple, general ideas in order to link to learner's prior knowledge (or experience). The remainder of the instruction presents progressively more complex ideas in order to elaborate on the ones previously presented. The purpose of this study is to investigate whether Elaboration Theory strategies are still able to serve as effective guidelines for designing hypermedia materials with the latest emerging technologies.

The study is primarily designed to compare an Elaboration-Theory-Based hypertext with a linear hypertext that does not employ any instructional theories and principles. The investigated instructional treatment is to design a unit of hypertext materials by using one of the major elaboration strategies proposed by Reigeluth (1987): sequencing the instructional materials using a simple-to-complex format. In compliance with the purpose of the study, this research study is to determine whether the Elaboration-Theory-Based hypertext, designed by using Reigeluth's instructional strategies, more effective than a non-theory hypertext in facilitating student achievement of different educational objectives.

Instructional Treatments: The instructional content used for designing the instructional treatments is the 2000-word heart content module developed by Dwyer and Lamberski (2000).

1. Control Group: Linear hypertext as a control group

In this design of treatment, the original heart content was converted into HTML format and put onto the World Wide Web. Learners determined their own learning paces by dragging the scrolling bar up and down on the right side of the browser.

2. Experimental Group: Elaboration-Theory-Based hypertext

This treatment employed one of the major elaboration strategies: sequencing the instructional materials by using a simple-to-complex format. The first frame (lesson) of the instruction was designed to represent central theme of the instruction. One epitome was created to serve as an advanced organizer to provide learners
with the most relevant and inclusive introductory materials. The subsequent frames (lessons) were designed to elaborate on different parts of the epitome.

Research Design

The research design in the study is a randomized posttest with a control group design. The independent variable is the type of hypertext. The dependent variables are three criterion tests: terminology test, identification test and comprehension test that are given immediately after the students finish reading the online instructional treatments. A t-test statistics measure is used to analyze collected data.

Procedure and Data Analysis

Thirty-three college students participated in this study. Sixteen of them were randomly assigned to the control group, seventeen in the experimental group. The results of the study (see Table 1) indicate statistically significant differences between the control group and the experimental group. That is, treatment designed by using elaboration theory, was superior to the control treatment (non-theory and linear hypertext) for the identification and terminology tests, but not for the comprehension test.

Concluding Comments

According to the above results, the Elaboration-Theory-Based hypertext indeed improved students' learning achievements in terms of identification and terminology tests. However, it did not enhance students' comprehension capabilities. To investigate potential solutions to the aforementioned problem, item analysis for the comprehension test was conducted. The results indicated the item difficulties of 11 out of 20 items were not desirable (less than 0.5). Therefore, a more thorough unit of hypertext instruction designed by using more elaboration strategies should be further investigated to improve those identified comprehension items.

Abstract: This paper will discuss Computer Based Virtual Field Trips that use technologies commonly found in public schools in the United States. The discussion will focus on the advantages of both using and creating these field trips for an instructional situation. A virtual field trip to Cumberland Island National Seashore, St. Marys, GA will be used as a point of discussion for the technologies involved and the value of their use for instruction in a science classroom. While this field trip is being used as a discussion point, the techniques and advantages identified can be applied over a P-16 grade range in all subject areas. If the decision is made by an instructor to create a virtual field trip, the technologies used can be as simple as using digital pictures and text in Microsoft PowerPoint or Hyperstudio or as complex as using digital video and panoramas in Macromedia Director. The level of complexity will depend on the technology available and skills of the developers.

Virtual field trips are a hot buzzword for integrating technology into the curriculum. If one does a web search using “Virtual Field Trip” as a key phase, hundreds of sites will be identified. These sites are overwhelmingly web based and provide an abundance of pictures with limited information about locations that are deemed to have educational value. Krupnick, states that, “The Web is now crowded with sites that are considered ‘Virtual Field Trips’ and they vary a great deal in content and usefulness.” She further states that, “For teachers who already have a curricular unit assembled and are looking for online enhancements, these are adequate. But for teachers who are looking for a source of new and exciting curriculum such sites are only a starting point. In order to make them useful, an instructor would need to develop curriculum.” (2000, p. 43)

The approach taken in this paper is that a virtual field trip is much more than a web-based presentation of a location. Our focus is to show how to design a field trip based on curriculum content that allows the student to "learn" from the field trip in a way that is similar to actually taking the field trip. Coulter states, “The key is for (instruction) to drive the technology implementation and not vice versa, despite pressures to integrate technology into the classroom... virtual field trips ... enable students to refine and extend their growing understanding as they explore other parts of the world.” (2000, p. 49)
In educational situations actual field trips need to be more than “just a day away from school,” with limited tangential educational purpose. They should be as real a connection to the “real world” as possible. A normal day field trip does not offer sufficient time to take full advantage of all a site has to offer. Bellan and Sheurman (1998) discuss ideas about actual and virtual field trips and state pitfalls of both. Their article outlines the teacher involvement necessary to alleviate some of the pitfalls. Among these are a teacher visiting both the actual and virtual sites, the teacher’s plan for student use of a virtual site, student use of the virtual site before visiting actual sites, and follow up instruction using both the virtual and actual trip experiences. Taking the field trip on the computer does not eliminate all the concerns about how field trips are used. The virtual field trip is usually not sufficient by itself. Pre-planning the trip and the follow-up experiences should be addressed as part of the teacher’s curriculum. In addition we suggest a virtual field trip should be developed by the teacher to be used in connection with an actual field trip to the site.

**Definition of a Virtual Field Trip**

Virtual field trips as referred to in this paper, are computer-based simulations of an actual field trip, which allows the user to vicariously experience the environment of the intended location. They provide the teacher and learner the opportunity to explore aspects of an actual trip without leaving the classroom. They should include all elements of a well-designed field trip and provide the student with experiences that are beyond those that could be obtained from a pamphlet about or a photo display of the location. Stainfield, Fisher, et. al. (2000) feel that virtual refers to “digital alternative representations of reality” and that a virtual field trip is not an attempt to create a virtual reality.

**The Power of Instructor Designed Virtual Field Trips**

Instructors can create their own virtual field trip with their students by using a digital camera. By planning what they would like to include, the field trip can be designed to meet the objectives of the specific instructional situation. The site used for the virtual trip can be one that is within the student’s local community. Choosing a site that can be visited by the class or a student’s family will vastly increase the educational value of the experience. This requires that teachers must have control in creating the trip to meet their curricular needs. Student involvement in the creation of the virtual field trip can give power to the experience. This can take the form of; collecting information at school, using aspects of the technology in the construction of the product, taking the actual field trip and gathering the images and information that is presented in the virtual field trip. This type of involvement focuses student’s attention and learning on the intricate aspects of the content presented. In addition it provides ownership by the students of the project and focuses their learning of the curricular content. Last, but not least, it provides opportunities for students to use the technology in a real world situation, which addresses the NETS standards by preparing them to function in a technology rich information society.

**Advantages of Creating a Virtual Field Trip**

The main advantage of a virtual field trip is that it can be used to meet the objectives of the curriculum and the needs and ability levels of the students. Other advantages include:

- providing opportunities for repeated visitations to the site for continued study.
- allowing the teacher to focus on one specific aspect of the trip at a time.
- providing for the presentation of a wider variety of experiences than may be possible on one trip.
- illustrating time sensitive issues that could not be viewed on a single actual trip.
- allowing classes in a different geological location to visit and compare with resources in their own area.
- providing integration of the multiple aspects of the field trip into a number of different curriculum areas.
- allowing for commonality of experiences by all participants.
- allowing students to take a closer look at areas that could not be fully explored during an actual field trip.
- using for assessment purposes.
- sharing with colleagues and parents.
- using repeatedly by the teacher year after year.

When teachers use a virtual field trip in conjunction with an actual field trip to the same site, a virtual trip can serve as a motivator for the trip, or as an advanced organizer for the day’s activities. It also encourages learners to plan and prepare for activities to be carried out on the trip or can provide a simulation for students who may not have been able to attend the actual field trip.

**Limitations of a Virtual Field Trip**

There are two major limitations to using a virtual field trip. The first is the availability of a field trip that meets the objectives of the curriculum. Commercially available and Web based field trips are designed for a large audience and may need to be adapted to meet an individual instructor's curriculum needs. The second limitation focuses on the designer's expertise in the content area and appropriate pedagogy for the field trip.

**Barriers, and the Paths over Them**

The main limitation in creating a virtual field trip is the time needed to create the experience. The teacher who wants to create a virtual field trip needs to find ways of involving others such as; colleagues, community members, students and parents. If the teacher views the design of the field trip as dynamic, constantly evolving, construction of both the actual and virtual field trips will grow over time.

Because curriculum design requires content expertise, another limitation is the creator's knowledge of the content area of the field trip and the curricular objectives. As teachers become involved with the design they often need to extend their content knowledge, thus increasing the time necessary to design the experience. On the positive side, they can get so involved that their personal knowledge increases and it becomes a professional development experience.

A third limitation is the availability of the technology. However with the increasing availability of technology in the schools, homes and work places this is becoming less of a barrier. Coupled with the availability of the technology is the teacher's ability to use the technology effectively. Again this can become a learning situation and thus increases the time to create the product. This limitation can be minimized by the involvement of colleagues, community members, students and parents.

**Creating a Virtual Field Trip**

The general steps for creating a virtual field are:

1. **Examine objectives of the course and choose a field trip that includes experiences that fit within the realm of the objectives and enhances learning.**

   The purpose of a virtual field trip may meet multiple objectives: to learn specific content, to experience a new venue, or to develop skills in documenting experiences and using technology.

2. **Create a concept map of the experiences to be included in the field trip.**

   A concept map provides an overview of all the elements to be included in the virtual field trip and acts as an organizing framework to build upon in construction of the final product. The concept map should not be considered the final blueprint for the field trip; rather it should be seen as a dynamic overview and a starting point from which the product evolves.

3. **Select the appropriate technology to be used based on the content and the curricular objectives of the trip.** The technology includes the organizing program and tools for collecting and presenting data.
The equipment and software used will depend on the complexity of the trip and the grade level of the students. Virtual field trips can vary in their complexity based upon the experience of the creator with the technology available.

4. Collect and organize materials to be included based on the curriculum objectives to be accomplished and the concept map.

Examples of desired materials might be: a) still pictures, both digital and photographs; b) videos; c. text; d) databases and graphs; and e) sound clips.

As materials are collected and organized decisions must be made. For example, panoramic videos can be used to give an overview of the location. If panoramas are to be used, decisions will have to be made beforehand as to the location and the concept to be illustrated.

5. Convert all materials to digital format.

When converting materials to digital format the question of designing for dual platforms (Windows and Mac OS) must be considered. While designing for dual platforms is not more difficult or time consuming, the decisions made about the format of the individual parts (pictures and text) must be considered to insure that they are appropriate for the platform(s) chosen. Making these decision early eliminates converting work later. Materials not in digital format need to be digitized.

6. Assemble all elements in the organizing program based on the concept map.

Here decisions on the format that the field trip will be presented in must be made. Will it be one stand-alone program presentation or a series of parts that can be accessed separately? Also, before assembling the materials one must consider the platforms that can present the materials. Will the field trip best meet the needs of the teacher if it is dual platform or is one platform sufficient? These decisions along with the assembler’s knowledge of presentation programs will determine if Macromedia Director, Hyperstudio, Power Point or any of the other available authoring programs meet the needs of the designed field trip. The choice of the authoring program used is often the assembler’s personal choice based on familiarity and skill with the program.

7. Evaluate the finished product to be sure it meets the objectives.

In a teacher created product, evaluation should be formative in nature, providing a continuously changing and evolving product. There will always be questions of; how could we do this better? what can be added to it? what are the differing needs of the learners using it? and how can each learner group add to the information presented?

When evaluating the effectiveness of a virtual field trip one should consider both the appropriateness and the effectiveness of the technology used in the presentation of the content. Children frequently experience learning situations indirectly thought technology by the use of pictures, time-lapse photography and interactive non-linear experiences that allow the learner to follow their interest and to revisit locations in the program as their interest grows. Technology should not be seen as a replacement for experiences but as an enhancement of these experiences. Technology can be used to enhance the senses, build interest and excitement or to review and analyze experiences. Digital cameras provide the technology necessary to; record experiences for later analysis without damaging the environment, document cause and effect relationships, record changes over time, document unique events, record images that give historical perspectives, open vistas of limited access to all learners, and reviewing and analyzing experiences.

We chose to illustrate the process of creating a virtual field trip within a course for Middle Grades pre-service teachers. Its objectives are to prepare the pre-service teachers to; 1) design and use field trips effectively in their classrooms, 2) effectively develop technology use and skills in their students and 3) illustrate an integrated curriculum approach to learning.
The Cumberland Island National Seashore: Virtual Field Trip (Clark, et al, 2002) has been effective in motivating our middle school pre-service teachers in several ways. The students actually look forward to getting up at 5 a.m. for a 6 a.m. departure and walking in the sun/rain/wind/heat/cold for twelve or more hours before returning home. The students are more attuned to the sites they will see and participate in activities on the island. For example;

- upon reaching the beach instead of thinking of swimming, they look for live buried shells.
- they have thought about the mathematics of figuring out a tree's canopy coverage, or a fountain's volume, and proceed with the task.
- they know what plants and animals are to be found and set about searching for them.
- they know how to use the digital camera to document necessary aspects of an unknown phenomena for later study or life form for later identification in their field manuals.
- they look for signs of man's influence on the environment and history of the area.
- they look for signs of the destructive effects of the feral horse and hog population on the environment.
- in the marsh and bogs they look more closely at the smaller forms of wildlife.
- they have a stronger awareness of what goes into a quality learning experience.
- upon returning from the actual trip they note what they saw, what they did not see, and organize their data and experience into a technology enriched presentation.

Conclusion

We feel that a virtual field trip that resides on a storage medium and not on the WWW has advantages in its effectiveness. The program is not dependent on access to or the vagaries of the Web, it runs faster, it is always accessible, and it focuses the student’s attention on the task at hand.

This paper uses the terms teacher created, creator, and assembler in an apparently interchangeable manner. This is due to the principle that while the teacher is the driving force in the design and creation of the virtual field trip; the tasks can be done in conjunction with students, parents, interested community members and colleagues. The technologies used to develop and create virtual field trips are commonly found in public schools today. This process of creating virtual field trips can be as simple as using digital pictures and text in Microsoft Power Point or Hyperstudio or as complex as using digital video and panoramas in Macro Media Director. The technology skills necessary in the creation of the field trip all are within the scope of the National Educational Technology Standards (NETS) for Teachers, and many are within the scope of the NETS for students.

A Typology for Identifying Teachers’ Progress in ICT uptake

Barney Clarkson, Edith Cowan University, Multimedia Department, Australia
b.clarkson@ecu.edu.au

Ron Oliver, Edith Cowan University, Multimedia Department, Australia
r.oliver@ecu.edu.au

Abstract: This paper describes the design of an instrument to help identify teachers' level of ICT uptake. The instrument takes the form of a typology matrix comprising four stages in ICT uptake across a continuum describing teachers’ levels of dependence. Identification of teachers’ positions in the typology matrix is determined by their affective, cognitive and demonstrated states of ICT application and use. The paper describes the process of determining the position of two elementary school teachers within the typology and discusses the reliability and validity of the instrument and the placement process.

Introduction

Schools and teachers are in midst of massive changes since the pressure to use information and communication technologies (ICT) began in the late 1980s. Addressing teachers' needs has become an important element for many school and educational systems around the Western world (Elmore, 1992). Unfortunately educational institutions under pressure to utilise ICT, have often found it easier to see the technology issues rather than the human ones (eg. Hodas, 1993; McClintock, 1988; Papert, 1998). The resulting outcomes have tended to be applications of ICT based on motives and directions that often fail to capitalise on the opportunities and affordances the new technologies can bring to teaching and learning.

The Need For a Scale of ICT Uptake

Much of the professional development for educators to aid in their ICT uptake has not had the expected effect, even though there have been many attempts at providing support for teachers during their ICT progression and many attempts at describing various ICT diffusion or uptake processes (Cheung, 1999; Christensen, 1997; Mahajan & Peterson, 1985; Marcinkiewicz, 1994; Russell, 1995; Sandholtz, Ringstaff, & Dwyer, 1992). Holloway (1996) suggests the processes may be too techno-centric and need to consider a more humanist perspective.

Writers concerned with change in education argue that most effective approaches to professional development consider both the whole system, and the people in it (eg. Fullan, 1999). Part of the challenge of orchestrating any significant and sustained change in educational systems is that these entities have significant natural inertia, and much of the change is illusory and confused with movement —the never-ending and sometimes chaotic movement that is characteristic of large organizations (Huberman, 1992). Teachers need to learn and adapt in such an environment. In fact Fullan (1999) argues “that learning occurs on the edge of chaos, where a delicate balance must be maintained between too much and too little structure” (p.ix). This makes the argument that improving the balance between individual teachers needs and their professional development is important, since the divergence of an individual’s circumstances, pressures, resources and abilities could be vast.

One of the problems that often faces professional development for ICT uptake is that teachers come to the programs with vastly differing backgrounds and predispositions to learning. Their previous experiences and existing expertise plays a large part in influencing the form of professional development they need. Currently it is difficult to know how to differentiate among the teachers so that appropriate learning settings may be contrived (eg. Knowles, Holton, & Swanson, 1998). A number of researchers have discussed the training needs of teachers looking to use ICT as aids to their teaching and described strategies that can take teachers beyond their current zones of comfort (eg. Schrum, 1998). Within much of this discussion is an implicit understanding
of the need to be able to identify teachers' current development level with respect to ICT uptake along some
typology. It was this need that provided impetus to the project described in this paper which sought to develop
and validate such a typology.

**The Research Setting and The Model**
The principal aim of the research reported in this paper was to develop a framework by which teachers' pedagogies and capabilities with ICT could be mapped onto some multi-stepped scale as part of assessing their ICT uptake. The study was undertaken with interested teachers in two metropolitan elementary schools in Western Australia, over the second semester of their school year. This paper reports the four-stage typology of ICT uptake which was developed.
The typology was derived from a series of models of learning described by Brundage (1980) and Boud (1988) and with considerable input from studies of teachers and their teaching practices with ICT. In this sense it was grounded in the teachers' data as well as reliant on previous research. The model describes four stages: Dependence, Counter-Dependence, Independence and Interdependence (shown as Figure 1). These stages reflect typical phases through which all learners pass through as they achieve mastery on a new topic. ICT is simply another topic for learners to master, in this less techno-centric conception of ICT uptake as a learning issue.

![Figure 1: The four stages for learning new material (from Boud, 1988) and adapted to this model of ICT uptake](image)

Within each stage of the model, the relevant literature provides descriptions that can help to identify how teachers feel and react. Through these descriptions it would seem possible to allocate any teacher to a location on the scale. To improve triangulation and to ensure consistency of reaction from teachers, descriptions for the typology were further developed to provide a more sensitive means to identify teachers' positions. Three domains were developed for each of the stages to enable different aspects of teachers' experiences and predispositions to inform their placement. These three domains are described as: feelings, understandings and behaviours. The domains were chosen to match the domains of human activity proposed by Bloom in the 1950s and still a useful distinction (Krathwohl, Anderson, & Bloom, 2001). The stages describe teachers' affective states, their cognitive states and the ways these are manifest in their actual teaching. If these stages were truly distinct and credible, then it was expected in developing the typology that teachers would be located at one stage, with their ratings for feelings, understandings and behaviours falling roughly into roughly the same stage.

Following this line of reasoning, the typology seemed to promise a means by which, in theory, ICT uptake could be measured by progress along the four stages and within the three domains simultaneously. The typology was presented as a 4x3 matrix (Figure 2) with cells defining the basic layout. It was named the ADL uptake model in an attempt to capture the role of Autonomy, Dependence and Learning in the ICT uptake process.

![Figure 2: Four stages of ICT uptake proposed as the ADL model](image)

To enable the typology to be applied within general settings, distinct and unique descriptions for each of the cells were developed. These descriptions needed to provide ways to describe teachers across the 4 stages within the 3 domains. Fig. 3 demonstrates Descriptors taken from the Understandings row across the 4 stages.

![Figure 3: Example of Descriptors for the four stage model, in this case over the domain 'Understandings'](image)

Each cell of the 4x3 table was further elaborated with Pointers that are representative of that stage and domain. For example at Dependence, the teachers' Understanding might typically include some but probably not all of...
these: Wary of ICT’s flexibility, instability; questions own role; cannot yet comprehend ways to use ICT broadly; believes ICT is an object to be examined, learned, taught about; seeks explicit even unequivocal standards, regards explicit step-by-step guidance as critical; prefers single solutions.

These Descriptors and Pointers are not indicative of fixed immutable steps that every learner passes through but general and overall predictable patterns to their feelings, thoughts and behaviours, which are representative of each stage. Some will pass through them more quickly than others for example, but the distinctions are, in Brundage & MacKeracher’s terms, “an aid to analysis and ... not meant to reflect universal, absolute differences” (1980, p. 11).

Mapping the Data—Two Teachers’ Records

To test the utility and efficacy of the typology, a number of elementary teachers were interviewed and observed whilst teaching as a means to discover their understandings, feeling and behaviours in relation to their use of ICT in the classroom. The teachers were then mapped into the various cells of the typology and their positions investigated.

Using the data obtained for each of the teachers in the study, the ADL matrix was completed and teachers’ positions noted. It was a relatively simple process to fit the teachers into the four-stage ICT uptake scale and thus to give them some form of quantitative index that could be compared at a later date to ascertain if progress in terms of advancing their positions could be determined.

The findings indicated that credible roles like novice through to sustained ICT user were categories that could be identified for teachers fitted to this typology, although it was decided to avoid using role names as the interest was on classifying their current location or stage, and allowing them to move stages as they needed and as they progressed.

It was found that the quickest way to rate the teachers was to review their data record from interviews, notes etc and decide which cells represented them best. For validation purposes in the study, the teachers were mailed a copy of the completed table and each was asked to circle positions on the table which they felt were relevant and descriptive of themselves. Positions where the teachers marked multiple pointers provided sufficient evidence to suggest that they perceived themselves to be ‘in’ that cell. Remarkable commonality between the researchers’ predicted and teachers’ own ADL matrices was found.

Teachers’ positions within the typology were indicated on summary charts in which the cells that represented their status were shaded grey. For example a novice might have a chart (called their ADL location chart) with all the left column shaded, and nothing else (see Fig. 4).

Using The Typology

The following sections describe several teachers who were investigated and whose ICT uptake was judged and located on the ICT uptake location chart.

Teacher A: Paula.

At the end of the research period Paula was very much in control of her learning environment. She had realised a few years earlier that she was becoming irrelevant, and decided that she wasn’t prepared to continue unchanged in her teaching. When asked if the advent of the computer lab in her school had put extra pressure on her, she replied:

PAULA: I can only speak for me but it should have put pressure on everybody. It did to an extent, but on myself...because of my age... I wanted to last the distance, and I saw a lot of people {here at school} that I didn't want to be like. I didn't want to have their attitude, and I knew that I haven't perfected the craft of teaching because it is always changing... according to the demands of society. A lot of them haven't noticed that!  

This became the impetus for her to rethink her whole approach to teaching. She started telling her students that school was their job, not hers. She began to attend professional development courses that were going to help her change the way she thought and taught, and it had a kick-back effect on her usage of ICT:
INT: So you agreed to a plan that put a block of computers into a lab first, and class machines later? And you thought that was a good idea, but then...?

PAULA: It still is, but it is frustrating having to wait. With the way I think, and maybe a few others think, as subjects become more integrated and we go that way, and we bring aboard thinking skills, allow the kids to learn how to think, to set their goals and so on. Whatever. It means that they have to work more independently, they need to be more self-motivated, and given the opportunity to set their own goals. This is as opposed to someone playing entertainer, and pulling surprises out of a hat for the students each day. As kids set their own goals they learn to start saying I want to search on the Internet for something, I want to scan this picture in for this project, takes some digital photos and so on. Now, over three years we have gone from *a* lesson in the computer lab -- and it was really my lesson I was the one on the learning journey -- and now it's them telling me what they are doing and planning. {Intl :line86}

By the time Paula assembled her ICT uptake location chart, she was not only making use of ICT as a learning tool in her class, but she was also encouraging her students to do the same. In fact some of her Year 4 students were the school experts on various pieces of ICT:

PAULA: In my class there was a handful who were experts at taking photos, printing and down-loading. Another little kid decided he was interested in scanning. Now I haven't got a clue how to do those... I know they're not hard... but why should I bother? So I handed over to them. It's more of, me standing back, getting time to understand and observe {while they do the work}. The kids know that I can't down-load pictures. It might take me just five minutes to learn, but it's not as important to me as it is to them. When I get my own digital camera then it will be. So the kids don't come along [to school] to watch me work, instead I stand back and watch them. They are more in control of what they do. {Intl:line 212}

Although she could be described as highly student-centric in her approach, she had become a competent user of ICT; and it was harder still to fault her use of it in her teaching. She was willing to share ideas with others, was a mentor to Nora, the adjacent Year 3 teacher, and they left the room divider open permanently, so that they could share students, ideas and support. Her ICT planning and usage had become second nature to her, and she was focussed on her students' performance not her own. Her use of the Internet and e-mail as tools were indications that she had become not only Independent but also Interdependent in her ICT usage. Her ICT uptake location chart was very predictable (see Figure 5).

![Figure 5: Final ICT uptake location chart for Paula](image-url)

Very few of the teachers chose pointers in more than two columns, and very few did not choose all the cells in a column either. These facts provided support for the principle that there was some underlying pattern to the categorisations. Nevertheless, this did not explain all the charts. Some teachers' charts did clearly cover two columns—perhaps Paula's chart, Figure 5, was an example of this—and it was felt that there could be an explanation for this. Teachers who straddled multiple categories along the scale, it was decided, might be in the process of transition between categories. Support for this notion was strengthened by the observation that teachers rarely straddled more than two stages when they completed their chart. In Paula's case she may be showing evidence that she was covering two categories, or stages, but the fact that she was performing at the upper of the two stages (in other words, she had circled sufficient pointers in her Interdependence behaviours cell, the one at the bottom right of her chart) was good reason to allow her this categorisation. David was a better example of someone in transition.

Teacher B: David

Although he was negative about ICT, David bought a computer during the research period and began to make use of it at home. His interest levels were higher than his performance levels, as he found them initially confusing and was unwilling to try any but the most mundane activities with his students. He believed that the school and the Department of Education (his employer) expected him to teach students about ICT, and that they had never provided enough support to help him even start the process. He admitted that his usage was unsystematic, and felt that he was expected to show high levels of skill with computers all the time:
DAVID: Oh, I'm quite sure that I'm required to have every kid completely computer literate, and doing very complex computer type things, I'm sure that's happening here.  

Not only does he have unrealistic expectations of his own use, he puts pressure on himself as well. When one parent offered to help on Fridays, he was pleased and pressured in equal measures:

DAVID: .... I had the head of the P & C in my classroom, an absolutely wonderful person called Jacques, very very computer literate, and he's actually been in the classroom on Friday mornings, taking loads of kids doing word processing...

*INT: I saw your thanks to him in the newsletter.

DAVID: yes, but, I can see in his eyes, that he knows I don't know what the hell I'm doing. He's done extra things like buying a set of headphones, brought in a few CDs; and every Friday morning I wonder what the hell am I going to get Jacques to do on computers. So I feel pressurised there, I feel anxious and worried...  

It is apparent that David feels that he must provide all the direction when it comes to computer use. It is a focus of his attention and not a tool or a conduit to a learning purpose. These are the characteristics of a Dependent person on the ICT uptake typology. At the same time he admits that computers definitely have a place in schools, and that he would like to improve. He doesn't know how he will become an adopter of computers in his class, but he has some ideas which seem to simultaneously guide and stress him:

*INT: So how will you become this person moving from considering to adopting?

DAVID: ... I don't know. I don't have a clear idea in my head, or goal, of how the computer can be used in the classroom. To me it's always been a token gesture. Where you're rostering a child on a computer, and we were seen to be doing some something, but I can't see how it's integrated into the learning environment. I do actually like the idea very much of using it for remedial purposes, like teaching phonics, that sort of stuff. And I like the idea of using the Internet in the classroom.... ahhh, open-ended research type stuff; and I like the idea of being able to network with other teachers through the Internet.

David, with no clear idea of how computers can be used, and who regards their usage as part of a 'token gesture', is relatively low on the typology of ICT uptake. In summary he perceives it as a novelty or even a threat, is defensive about his lack of progress and seems unlikely to make any progress without specific and localised support. His understanding is limited, but as well as views about ICT as a teaching tool, he also envisages some more flexible and open-ended uses of ICT which suggests that his thinking at least is a little more towards Counter-Dependence than either his Feelings or his Behaviours. Hence his chart has a peak as shown in Figure 6.

![Figure 6: David's Initial ICT uptake location chart](image)

**Discussion**

The placement of the teachers on the chart provided a number of interesting findings which merit some discussion. In the first instance, the typology was found to provide quite consistent descriptions for the participating teachers. The teachers' positions in the table tended to be within the discrete stages across the 3 domains being used. There was a high degree of consistency in this suggesting that the typology was able to reliably place teachers in a stable position.

Furthermore there was a high degree of consistency between the positions which the researchers placed the teachers and where they placed themselves. This consistency provided some sense of triangulation of the data and provided some assurance that the typology could accurately place teachers.

In a number of instances teachers were found to sit in one stage but to have some connection with a cell in an adjacent stage. These instances tended to suggest teachers whose position on the typology was not stable and was indicative of a teacher who was perhaps moving along the typology to an advanced level of ICT uptake. This finding was confirmed on several occasions when such teachers were found to have moved positions along the typology to stages indicative of greater levels of ICT use and uptake.
Summary

This paper has described the design of an instrument to help identify teachers' level of ICT uptake. It was less techno-centric than many previous versions, and was shown to have some utility. Two aspects of describing a teacher's location were evident. Some fitted easily to the three domains of a category suggesting that they were characterised by that stage and some stability; others tended to straddle two (but rarely more) stages, suggesting that they were in the process of change.

All the possibilities for placement on the scale were expected to describe people with very different needs about ICT and expectations about ICT training. In fact it was evident that these teachers with their diverse views and different ratings on the ICT uptake typology, had quite different support needs and diverse professional development services. Thus the typology could be applied more widely. A useful next step could be the development of an instrument or questionnaire to investigate an alternative way to finetune the placement of people onto the grid, as the current one might provide too many cues to users who had seen it before.

The typology appears to provide a reliable and valid way to determine teachers' positions as users of ICT in their teaching and learning. Further study will be carried out to ensure the typology can be used effectively in mainstream settings. If and when this is possible, the typology would appear to provide considerable assistance as a means to helping to ensure that professional development programs can be targeted in meaningful ways to the recipients based on their needs and their current capabilities as users of ICT in their teaching.

Abstract: Action learning is effective learning and development through the use of real
life context based problems, applications, and solutions. At Grant MacEwan College, in
Edmonton, Alberta, Canada, emphasis in faculty instruction is on practical, real life
situations that faculty encounter in their classrooms and in teaching. Moving from a
program of presentations and passive participation, professional development at Grant
MacEwan now incorporates practical, hands-on experiences that reflect the current needs
of faculty through action learning. This new directive for professional development
focuses on making changes to the learning environment rather than forcing a personal
change in the faculty members teaching style.

Action Learning began in the corporate sector as a method for solving real life problems in a creative
and practical manner. It moved into educational settings, fitting well into graduate level programs that
based their course activities on constructivist and situated cognition learning theory (Ritland-Bannan,
1999). Similarly, it fit well with educators attempting to implement changes to their teaching methodology
(Beaty, 1999: Gold, 2001). Action learning is based on a team approach whose function it is to solve real
problems by trying various solutions, reflecting upon the impact of those solutions, and creating
improvements to those solutions.

If action learning can help companies solve problems, students learn through practical experience, and
teachers try new learning methodologies, can it help college instructors learn new ways of teaching with
technology? Grant MacEwan College educational technology designers thought it could.

Formerly a program of occasional one or two day presentations and passive participation, faculty
training in using technology for teaching and learning now focuses on practical, hands-on experiences that
reflect current needs of faculty. Using principles of action learning, college, program, and individual
faculty needs are addressed through continuous workshops and individual consultations that incorporate (a)
Context-based learning, (b) team support, (c) reflective questioning and (d) action based solutions.

A key concept in action learning is that of working on real problems with real people, in real situations
(Gallant, 2000). Workshops are marketed as possible solutions to problems faculty may be facing. For
example, the workshop on Web-based discussion forums is described in terms of addressing the problem of
promoting greater interactivity, deeper levels of analysis, more critical thinking, and improved
collaboration in course discussions. Instructors who attend these workshops come in response to a problem
they want to address. Attendance at these workshops is often a response to “just-in time” support required
for a project need. However, faculty members can and do request immediate one-on-one support if the
workshop schedule does fit their needs. This is not only required to meet the immediate need of a project.
It is also desirable because of the many different skill levels found within members of a team. Faculty
members have to feel comfortable asking for remedial as well as advanced skill development in the use of
technical applications (Schifter, 2000). Much of the training that goes on at MacEwan is comprised of
office visits to give immediate support and training to group and individual technology initiatives. Our
motto is “Yes, we make house calls!”

Context-based learning. Training is hands-on. Participants sit down at computers and work with
actual applications, with content they can use in their own teaching projects. The sessions are not
demonstrations but rather a combination of sequential skill building and peer assistance that enables them
to use a certain technology to solve their teaching problems. An illustrated manual is produced for each workshop; however it may or may not be used by all participants. It is not uncommon to see one or two members in each group trying things out by trial and error and ignoring the manual and the facilitator completely. Regardless of learning styles, the goal for all participants is to leave the session with a usable product that they can test, make changes to, and implement in their courses (Baylor, 2000).

Team support. This brings up the concept of teamwork and community. Whether instructors are in the same program or not, the experience of planning new actions to address a problem bind them. One of first activities in a Grant MacEwan workshop is getting to know the people around you in the training room. What program are they in? Where are their offices? What are they doing to solve a common problem? What are they trying? What is working? What is not? How are they using technology to solve this problem? Participants are given a list of the colleagues who attended the workshop so they can go back down the hall a few days later, and ask that person, “How did you do that thing in WebCT to allow your students to post their assignments again?” Forming a supportive network of colleagues is part of the plan in faculty training. When training is given to specific programs, a team approach is used to identify problems and evaluate solutions.

Reflective questioning and action based solutions. Faculty training based on action learning requires a team to constantly think about the results of a decision and how it will impact learning. MacEwan training is based on decisions that programs and instructors make and the actions that are taken as a result of that decision. Furthermore, once an action is implemented, instructors question and reflect upon the effectiveness and efficiency of that decision. Problems and mistakes are shared within workshops as learning opportunities. Because teaching with technology is new and unfamiliar to most faculty members, questions must be raised so that fears and concerns are addressed. Reflection about decisions, and changes to those decisions, are based on questions and consultation with team members. Final decisions, if there ever is such a thing, are made within the context of the instructors’ real situation after questions and reflection about initial actions.

As facilitators and trainers for our faculty, we try to be the contact that instructional teams use for linking to other groups. We try to be the catalyst to move them to evaluate their current mode of teaching. We try to monitor their process to see when and where our intervention can help. We try to set a climate that encourages trust and willingness to try new initiatives. And we try to be coaches who encourage and support faculty to take responsibility for their own professional development in the field of educational technology. This facilitation model (Marquardt, 1999) required by action learning principles helps faculty try new methodologies in teaching....new methodologies that incorporate technology and that are based on action learning.

Promoting Peer-to-Peer Discourse for Collaborative Mathematics in Canadian Grade 7 Classrooms

Jonathan Cohen, James Dai, Michael Wu, Troy Wu and Maria Klawe
E-GEMS Research Lab
University of British Columbia
Canada
egems@cs.ubc.ca

Abstract: Whereas traditional research on collaborative educational systems has primarily focused on how to define better modes of digital interaction, this approach is found lacking when applied to developing collaborative systems for elementary school aged children. It is creatively and collaboratively restrictive to filter the enthusiastic interactions of these excited 12-year-old children through progressively more complicated GUIs. Current E-GEMS research examines design factors of educational systems that recognize and facilitate the social context of the classroom and hopes to encourage peer-to-peer social discussion. By correlating observed interactions in the digital domain with those in the social domain, we hope to shed light on design factors of collaborative systems that can be an integral and exciting part of a child’s mathematical education. This paper describes the vessel of E-GEMS research into socially engaging design factors – the collaborative educational game PrimeClimb.

Introduction

PrimeClimb, as shown in the left image, is a collaborative game in which a pair of children attempt to climb to the top of a mountain of numbers together. In order to reach the top of each mountain, students must collaboratively avoid falling – a feat accomplished by recognizing shared common factors between the numbers on which they stand. Collaboration is reinforced through the fact that in order to reach the goal each player must observe their partner’s number in order to move without falling. There is a tool – the magnifying glass – that can be used to shed light on the factors of any number. Magnifying glasses are hint-giving resources that are limited and shared amongst the two players. Our observation sessions were used to provide feedback in developing the current design factors of the magnifying glass.

The Study

The sessions of the study proceeded as follows: the pairs of children were first given a pre-questionnaire to access their mathematic factorization skills and general attitudes toward collaboration in math and computer games. They then played PrimeClimb together for 20 minutes and the session ended with a post-questionnaire that reassessed their math skills and attitudes. The focus of the PrimeClimb study has been to
analyze the social context of collaboration in a digital environment in terms of verbal and non-verbal interactions. Our data capture and analysis methodology must reflect this focus. Each play session was computer-logged and video-recorded. In order to correlate the digital events in the computer log with social discussion and interactions, an absolute clock was displayed on the game screen at all times. Each video captured a player's upper body along with her game screen; thus two tapes were produced from each session (see the right image, the figure has been blurred to preserve the subject's identity). Captured audio transcripts have proved successful in correlating digital events to facilitate design analysis in ethnography (Suchman, 2000) and math education research (Pirie, 1996). We hope to use our captured video data to correlate the social interactions with the PrimeClimb game events.

The detailed analysis of the PrimeClimb study data is underway. A brief glance already reveals a couple of encouraging signs. Firstly, different categories of social interactions of children playing PrimeClimb are becoming increasingly clear. As in past research from mathematics education, the categorization of peer-to-peer discussion in a mathematical context must take place first and foremost before the analysis of the pedagogical values of those categories can be carried out (Pirie, 1998). A few possible patterns of interactions have emerged that include: a player explaining to the other player why a move is not allowed using mathematical language, a player explaining the reason for a failed move using mathematical knowledge and a player strategizing and logically planning a series of moves. An example of the latter is when a player states that he/she is on a prime number and encouraging her partner to move as high as possible (this is an easy strategy but could prove faulty as multiples of prime numbers share common factors). We hope to apply this categorization and consequent analysis of peer-to-peer discussion about math in our computer supported collaborative environment. Secondly, we have noted that all the children had very little difficulty grasping the interface to the game — a result of multiple prototype sessions that have shaped the game interface. This means PrimeClimb is able to be a stable foundation upon which other research questions about collaboration can be launched. It has been argued that educational games should not be specially designed for girls at the risk of marginalizing them, instead games should be designed non-gender specifically in which the players can seek their own identities through collaborative tackling of the challenge at hand (Cassel 2000). PrimeClimb seems to have succeeded in this respect so far as boys and girls employed a vast array of strategies and were all readily accommodated by the game.

Conclusion

The data collection part of the PrimeClimb study has been completed and the data analysis has begun with promising signs. Our ultimate vision is to build collaborative educational systems that fit seamlessly into and facilitate the social context of the classroom — this study has so far shown that ethnography and math education research have methodologies that can provide valuable insights.

Distance Learning Instruction: A New Model of Assessment  
By Vicki L. Cohen, Fairleigh Dickinson University

Background
Distance learning is rapidly gaining acceptance as a valid means of course delivery in educational institutions across the country. With distance learning becoming an accepted form of instruction, these institutions are struggling to enhance the quality of teaching, learning and scholarship over the Internet while trying to effectively integrate this type of instruction into the curriculum. Increasingly educational institutions are employing this type of learning as part of their course offerings; in addition, many “virtual universities” sponsored by state departments or through commercial endeavors are offering a variety of programs and degrees via computer-mediated distance learning courses. Is this an effective way to offer instruction? What is the best way to assess this type of instruction?

As more and more institutes of higher education start offering computer-mediated distance learning courses, it becomes increasingly important that these courses are evaluated effectively. This new paradigm of learning requires a new model of assessment. This paper presents a model that focuses on six constructs that computer-mediated distance learning courses should examine: Teaching and Learning, Developing a Community of Learners, the Instructor, The Student, Implementation of the Course, and Technology Use. These constructs become important elements in the design and evaluation of distance learning classes.

The Model for Assessing Distance Learning
When looking at the first construct, Teaching and Learning, research supports that students of all ages who are provided easy access to well-crafted computer-mediated distance learning classes generally have a positive experience taking this type of course (Abbott and Faris, 2000; Baron and McKay, 2001; Gagne and Shepherd, 2001; Mitra and Steffensmeier, 2000). However, these studies also point out that an increase in positive attitude is directly related to instructional approaches used, meaningful assignments required, supportive faculty, and involvement in meaningful discussion groups (Abbott and Faris, 2000). As Baron and McKay (2001) point out, having the requisite computer proficiency also affected students’ perceptions of the course.

Research also suggests that distance learning can provide the same level of academic excellence as courses taught in traditional modes. Moore and Thompson (1990, 1997) reviewed much of the research from the 1980’s and 1990’s on the effectiveness of distance learning, which included not only computer-mediated learning, but two-way interactive video and a variety of other technologies, as well. They concluded that distance education was considered effective when measured by the achievement of learning, by the attitudes of students and teachers, and by return on investment.

Developing a Community of Learners is the second construct to consider when assessing distance learning instruction. Educators are increasingly emphasizing the importance of electronic communities in distance learning courses as a key to effective implementation (Creed, 1996; Herrmann, 1998; Illinois Online Network, 2000; MacKinnon, 2000; Palloff
and Pratt, 1999; Poole, 2000). As Palloff and Pratt (1999) say: “In distance education, attention needs to be paid to the developing sense of community within the group of participants in order for the learning process to be successful” (p.29). The role of the community is an essential component for the success of any distance learning class.

When considering the third construct, The Instructor, in an online distance learning course, the role of the instructor needs to be examined. The instructor no longer stands in front of the room imparting information, directing all interaction, and facilitating activities. Instead, instructors must take advantage of the constructivist online course and create an environment that is learner-centered, collaborative, and egalitarian in approach. The governing principle is that learning is an active process in which learners construct rather than acquire knowledge and the instructor’s role is to support that construction rather than impart knowledge (Grossman and Wagner, 2000). Palloff and Pratt (1999) categorize the various tasks and roles required of an online instructor into four general areas: pedagogical, social, managerial, and technical. In the pedagogical area, the instructor must know how to design and implement an effective hands-on course and create an environment, which promotes interaction and exchange between all involved. In the social area, the instructor must direct all social intercourse that occurs online and ensure that communication is not just between instructor-student but is a multifaceted pattern, involving student-student-instructor. In the managerial area, the instructor must know how to manage a multitude of tasks and organize a multitude of files. Oftentimes, the managerial function can become overwhelming and an effective instructor utilizes organizational skills and timesaving techniques. Lastly, in the technical area, the instructor must be technically proficient so that the course runs smoothly. The instructor must provide technical feedback to students on basic requirements for exchanging and reading files, and using software, browsers, and operating systems. In a distance learning course, the role of the instructor changes dramatically.

In reviewing the next construct, The Student, the role of the student also changes significantly in a distance learning course. Many students will find the transition to this new type of online learning to be difficult, especially if they are used to a more traditional course where they are “fed” knowledge and evaluated using a test. Students in an online course must be active and engaged in knowledge generation. They cannot sit passively and expect the course to be given to them by the instructor. Palloff and Pratt (1999) categorize the role of the learner in an online course into three areas: knowledge generation, collaboration, and process management. In knowledge generation the student must learn how to construct and generate his/her own knowledge base. In collaboration, the student must learn how to collaborate electronically with other students via e-mail and discussion forums. In process management the student must take the responsibility for managing his/her time, as well as taking the initiative for researching topics and concepts. The student must learn how to manage the process of learning in a constructivist online course. This is an important construct to consider in assessing distance learning courses due to the low completion rate of students enrolled in computer-mediated distance learning courses.
One of the more important aspects of computer-mediated distance learning is effective implementation of the course which in the fourth construct, *Implementation*. This covers the basic instructional design of the course, the infrastructure available to support the course, the quality of the access to the course, and the level of technical support available. These factors affect each student’s ability to access and successfully complete an online course.

The last construct, *Technology Use*, looks at how often students use various components of the course, and find each component useful. It is highly recommended that different aspects of the course be assessed for frequency of use and degree of usefulness. Such aspects that could be assessed are: the Discussion Forum, the Announcement Feature, the chat room, the white board, the Student Drop Box (where assignments are uploaded), the learning links, the lecture notes, the schedule of assignments, the syllabus, and the e-mail feature. This information will be very useful in the revision and implementation of the course.

**Discussion**

Computer-mediated distance learning involves a whole new array of factors to consider in the teaching-learning process. However, although distance learning courses involve various new factors to consider in their design and assessment, distance learning courses are fundamentally the same as any other course offered to students-- the basic denominator is effective instruction. The modality of delivering the course may change, but the basic tenants of good pedagogical theory remain the same. Although we are transforming education into a 21st century enterprise that utilizes the latest technological advances, the basic issues remain constant: what is effective instruction and how can we best teach to students who possess different learning styles and different competencies? How can we better prepare instructors to be effective? These are the questions we need to keep in mind as we conduct further research into the field of distance learning. In terms of effective course design, distance learning continues to represent one point along a continuum of design options, one other mode of delivery to consider.

The constructs outlined in this paper are those that should be considered in all courses; they are applied in somewhat different contexts within a distance learning course. As we move forward technologically, our theories of learning and instruction need to be applied consistently and persistently to the development of all courses, and our attention needs to be on the quality of the instruction, not on the modality of delivery. This “new” paradigm of learning needs to be grounded in time-tested and research-based theories of learning to ensure that our students receive the quality instruction they deserve.

**Overview of This Session**

The session at Ed-Media will present this new model of assessment by examining what the research recommends for each construct. A visual model will be presented and each construct will be reviewed according to what is recommended to assess this area. The session will demonstrate an assessment form that has been developed to assess the author’s distance learning class, Literacy and Technology Across the Curriculum, that is
being offered at Fairleigh Dickinson University. The assessment form will be examined and copies will be distributed to participants. Preliminary data collected from the course will be presented. Specific examples of how this model helped the author to design and implement this course will be demonstrated. Questions and discussion on assessment in distance learning instruction will conclude this session.

Learning and Retention in Data Structures: A Comparison of Visualization, Text, and Combined Methods

Vikrant Colaso, Ajeaaz Kamal, Purvi Saraiya, Chris North, Scott McCrickard, and Clifford A. Shaffer
Department of Computer Science
Virginia Polytechnic Institute and State University
Blacksburg, VA 24061 USA
http://infovis.cs.vt.edu/

Abstract: Numerous studies have been conducted to evaluate the effect of animated visualizations on students learning data structures, but few have attempted to evaluate the retention of information gained from visualizations. Our work focuses on comparing different media used for teaching data structures, particularly as they affect the learning process over time. Results from our empirical studies suggest that a combination of text and visualization helps students retain knowledge better than either approach alone.

Introduction
In computer science education, algorithms and data structures are complex topics and difficult for students to learn. Animated visualizations that graphically depict the processing steps of data structure operations are frequently developed as instructional media to help students learn. Many studies have been conducted to evaluate the effectiveness of these visualizations for learning (see Hundhausen 2002 or Wilson 1996 for a review). However, results have generally been negative, typically showing no significant difference between visualizations and traditional teaching methods. Minor design features seem to have major impact on effectiveness. Furthermore, few studies have attempted to evaluate students' long-term retention of information gained from data structure visualizations, the ultimate goal of education. A related study (Palmiter 1991) found that animated demonstrations to teach software user interfaces improved student performance over a textual manual in the short term, but did not maintain performance in the long term. It is possible that students merely mimicked the steps of the animations at first without actually understanding the steps as required for long term retention. We present a series of studies aimed to examine these issues.

Results
The goal of the first study was to compare different interaction strategies of data structure visualizations. 60 undergraduate CS students studied the AVL Tree data structure for 15 minutes using one of 3 methods: (1) a textual material derived from Shaffer’s textbook (2001), (2) the Arsen visualization (Gogeshvili 2001) which simply animates the tree operations initiated by users, or (3) the BinaryTreesome visualization (Gustafson 1998) which quizzes students to perform the operation steps themselves while providing hints. Students then answered a 15-minute closed-book test containing 3 procedural questions about the ‘insert’, ‘delete’, and ‘find’ tree operations, and 2 conceptual questions about higher-level concepts.

The data (table 1) indicate that all 3 methods resulted in similar student performance on the test questions, except for the ‘delete’ operation question which had significantly better scores from the students who used the text material (p<0.05). This may be due to the open-ended nature of the visualization tools, which required users to discover and explore their full functionality to learn all the AVL tree operations. Many students simply may have forgotten to explore the ‘delete’ operation in the visualizations or ran out of time, whereas the text ensured coverage of the material and helped students to pace themselves. This indicates that open-ended visualizations should be accompanied by guidance material, and led to our examination of a combined text and visualization approach in the next study. The Arsen visualization received significantly better subjective satisfaction ratings from students than the other two methods (p<0.05) and a weak effect over BinaryTreesome on the ‘delete’ question (p<0.1), indicating some advantage of the simple animated visualization method.

Table 1: Mean scores and ratings, 1st study.
The goal of the second study was to examine the effect of data structure visualization on longer-term knowledge retention. 49 undergraduate CS students studied the Depth-First and Breadth-First Search graph traversals for 20 minutes using one of 3 methods: (1) a textual material from Shaffer's textbook, (2) Saraiya's visualization (Saraiya 2001) which lets users step through the operations, or (3) the combination of (1) and (2). Students then answered a 10-minute closed-book test containing 3 procedural and 2 conceptual questions. After a period of 15 days, students again answered a second, similar test without reviewing the study material.

Overall, students scored similarly on the first test across all methods (table 2). Significant effects between methods were not found on either test. However, on average, students' scores decreased on the second test by 21% with the text method, by 11% with the visualization method, and by only 7% with the combined method. The 15-day waiting period had a significant effect on test scores (p<0.05). It had a significant detrimental effect on the text users (p<0.01) and a weak effect on the visualization users (p<0.1). No effect was detected for the combined method users. This data indicates a non-significant trend towards the combined method providing better retention. In future work, student tests should contain many more questions to enable higher resolution scores and more conclusive statistics. Strangely, on one conceptual analysis question, students' scores actually increased remarkably by 25% on average for the visualization and combined methods, while the text method scores remained constant. In subjective satisfaction ratings, the text method was the clear loser (p<0.01). On average, students most preferred the combined method.

Conclusions and Future Work

For teaching data structures, we recommend a learning method that combines visualization and text. Students are clearly dissatisfied with usual text materials, but visualization alone can lead to gaps in knowledge. Since subjects perceive that visualizations are very helpful, visualizations will stimulate and motivate them to learn new topics. Visualizations can help to drive concepts into long-term memory. Accompanying text will ensure adequate coverage of the concepts. This approach simultaneously enables focus as well as open-ended exploration by students. Even in time pressure learning periods, students were able to juggle both learning methods to produce good performance, including taking time to learn the visualization tool itself.

Current research in algorithm visualizations suggests that actively engaging students while they are watching visualizations can increase their effectiveness (Hundhausen et al. 2002). This would support our hypothesis that the visualizations in the first experiment failed because students were not guided to study the 'delete' operation. One approach to active engagement is to supply guide questions to be answered while the visualization is being studied. In addition to active engagement, we believe that there is an identifiable set of key features that are incorporated into nearly all successful visualizations. We currently hypothesize that this feature set includes: User control of the pace of the visualization animation; the ability to test hypotheses by allowing users to enter input; display of both logical and physical views of a data structure; the ability to backup the animation to replay critical steps; and a pseudocode display of the algorithm, keyed to the steps being visualized. We are presently conducting studies to measure the magnitude of the contribution of each of these features using a controlled visualization toolset.

New Pedagogies and Re-Usable Learning Objects: 
Toward a Different Role for an LMS

Betty Collis & Allard Strijker
University of Twente, The Netherlands
Collis@edtce.utwente.nl, strijker@edtce.utwente.nl

Abstract While the idea of reusing objects in digital learning environments is not new, continual strides are being made toward improving the prospects of reusability. A major trend in company training settings is to think of reusability in terms of a LMS (learning management systems), but where instructor use and pedagogies are little considered. We describe an approach to re-use based on a pedagogical model that puts learner interaction and contribution in the driving role and which sees LMSs and LCMSs as tools for the instructor or learner.

LMSs, LCMSs: Where is the Instructor?

There is currently much attention in the business world to the re-use of learning objects. Frequently this occurs in the context of the introduction of "e-learning" where the latter runs separately from "classroom courses". E-learning is typically seen as being instructor-free or -neutral, in order to capitalize on an "any time, anywhere" motivation. Complex systems, called learning management systems (LMSs) and learning content management systems (LCMSs), are proliferating, generally based on the underlying assumption that the system itself will select and deliver the learning experience, based on some level of sophisticated user modelling. LMSs are defined as systems "to manage learners, keeping track of their progress and performance across all types of learning activities" while LCMSs manage content or learning objects to "serve up to the right learner at the right time" (Chapman & Hall, 2001, p. 11). LCMSs typically include content-development tools, being in effect a new iteration of the long series of attempts to bring authoring tools into mainstream use for computer-supported learning. "Content assembly" and "publish learning" into different "output formats" are key tasks of LCMSs (Chapman & Hall, p. 16).

Meanwhile at the same time as commercial LCMSs and LMSs are being taken up for "e-learning" in company training settings, the use of Web-based course-management systems, also called online educational delivery systems (Landon, http://www.c2t2.ca/landonline/), continues to grow in importance particularly in support of instructor-led courses with or without a classroom component. Course-management systems (CMSs, not to be confused with content-management systems, also sometimes called CMSs) integrate content delivery, communication, learner activities, collaborative work support, feedback, testing, portfolio development, groupware tools, and administrative tools for the instructor. Selection of content objects is only part of the use of an online educational delivery system, and in many cases a minor part.

The relationship of LMSs and LCMSs to instructor-led classroom or blended learning is not yet much studied. Partially this is because the use of LMSs and LCMSs is still new, and most companies making these major purchases are still in the phasing-in stages. More fundamentally, it is because those responsible for LMS and LCMS use in the organization tend to operate separate from the "business as usual" instructor-led courses which are typically the candidates for extension via an online delivery system. The fundamental issue is: Where is the heart of the learning process? In the delivery of pre-made learning objects or in the support of learning activities involving human interaction and problem solving in workplace contexts making use of in-house experience? We believe that in a company learning context the emphasis should be on the latter (Collis, 2001; Collis & Winnips, 2001). When we start with a pedagogy based on the solving of real workplace problems ("authentic learning", Harrington, Reeves, & Oliver, 2001) where the interaction with others is critical we
come to a different view on reusability, and the technologies that support it. This relationship is part of a research project involving the Faculty of Educational Science and Technology at the University of Twente and the Shell Learning Centre. This paper will discuss some aspects of the on-going work.

Pedagogical Base: Focus on Contribution Intended for Reuse

What is a pedagogical aim that is highly related to re-use? We offer the proposition that it is not an aim primarily related to finding "instructional" content from elsewhere, but rather one with a strong orientation toward learning from experiences, from one's own and from those of others. This involves a pedagogical shift, away from an emphasis on learning as acquisition of predetermined content, toward a balance that includes or even emphasizes learning as participating and contributing to the learning experience in a way which can be captured and reused by others (Collis & Moonen, 2001; Collis & Strijker, 2002; Sfard, 1998). The basis of this pedagogy is educational (see also for example, Kearsley & Shneiderman, 1998) but it also is based on strategic and practical considerations. By an approach in which participants themselves contribute resources in a way that is intended for use by others during the course itself and in subsequent cycles of the course, a large collection of locally relevant resources is accumulated on an on-going basis based predominately on the work of the participants and thus less on the preliminary work of instructor or learning-object designer. This involves shifting the costs in terms of preparation time, from the content producer or instructor to the participants (Collis & Moonen, 2001). The resources accumulated fit with the style and level of the local participants (avoiding the "not invented here" problem), and in the company setting particularly, the tacit knowledge of the participants is made available to others in the institution (Collis & Winnips, 2001). An important point in this pedagogy is that many of the reusable resources are not to be seen as professionally made self-contained study materials; their creation, use, and reuse comes from the way the instructor or learner sees them as helpful for learning activities based on actual workplace problems.

The reuse of submitted contributions however is not automatic simply because the contributions are available to all in the course environment. Their reuse comes primarily from the pedagogy used by the instructor. As an example, participants can be asked to study one or more of the contributions of others in the current course or previous courses if available for reuse, and as the next activity compare and contrast their own workplace situations with those of their peers. Many such guided activities have been in use at the University of Twente for several years (De Boer & Collis, 2001); in the company context the pedagogical experience is only at the starting point.

For the products of such activities to be reusable as digital resources in other learning settings, the underlying database and system technology as well as the user interface must meet several requirements.

Technology Requirements

The technology required for support of this pedagogy requires an underlying object-oriented database. We suggest that gradually, an experience management architecture (Layton, 1999) will need to integrate the now-familiar course management systems with systems such as LMSs and LCMS as well as others. Figure 1 shows the architecture that we are currently researching.
For contribution-based reusability to grow in an institution, specific technical tools and user interface functionalities are critical. First, there must be a simple way for participants (instructors and learners) to enter new resources into a common database. Figure 2 shows one of the templates we make directly available in the course environments running under our local TeleTOP course-management system.
At the moment that an object is thus submitted into the database, metadata based on SCORM standards can be automatically assigned for some of the SCORM fields. A new document containing a metadata record is created automatically for each submitted item and stored in a metadata database.

In the TeleTOP system, the submitted items can be directly made available to all course participants for re-use in subsequent learning activities. The instructor decides this, and can decide that all participants have direct read and write rights at one extreme, or at another, that only an object chosen by the instructor is re-used in a read-only format at the other extreme.

For the submitted objects to be reused outside of the immediate course context as well as within it, the instructor needs to make a selection of which materials are good candidates for reuse. For these selected objects, the instructor can then add a broader range of metadata to help in the later retrieval process. Figure 3 shows the combination of automatically affixed metadata and the possibilities for local entries.
Figure 3. Metadata supplement template, ready for submission

Note that it is not every item submitted during the course which requires this localizing attention; only the relatively select and small sample that the instructor sees as good candidates for reuse. There is automatic XML representation of metadata documents generated within the TeleTOP system.

Subsequent searches of the objects in the database to look for candidates for reuse are made via the metadata document forms, which are in turn related to the actual submitted objects and can facilitate their being copied into the next desired environment. A simple interface is available to support the search process using any keywords on the metadata documents, and to facilitate the copying process, to move the items selected for reuse into a new course environment. In the instructor-led course, it is the instructor, not a LCMS or LMS, that makes these decisions. The LCMS can help the instructor be aware of resources that are available and the LMS can help the instructor be better attuned to the learning histories of the participants. But, in this sort of contribution approach, it is the instructor (or course manager or facilitator or even the learner) who decides what learning objects are most helpful for the problem-based activities that form the heart of the course.

Through the combination of these sorts of technologies and pedagogies, and in the implementation context of a course as a activity and contribution-oriented setting, a number of the barriers limiting the potential reuse of digital resources can be addressed, particularly those that relate to fit with the local context. In a (multinational) company training setting, the reuse aspect also brings a gradual increase in the sharing of in-house knowledge and experience (Collis & Winnips, 2001).

Fostering Inquiry-based Learning in Technology-rich Learning Environments: The Inquiry Page in the GK12 Fellowship Program

Sharon L. Comstock (scomstoc@uiuc.edu), Bertram C. Bruce (chip@uiuc.edu) University of Illinois at Urbana-Champaign
Delwyn Harnisch (harnish@unl.edu) University of Nebraska at Lincoln
Bharat Mehra (b-mehral@uiuc.edu) University of Illinois at Urbana-Champaign

Abstract: This paper analyzes the uses of the Inquiry Page (www.inquiry.uiuc.edu) in the National Science Foundation GK-12 Fellowship Program*, where scientist-fellows and K-12 teachers partner to integrate the use of computer-based modeling, scientific visualization, and informatics in science and mathematics education. The Inquiry Page is a web-based, knowledge-building tool that facilitates and fosters real-world application of inquiry-based learning. By creating “Inquiry Units” teachers and learners collaboratively engage in the inquiry path, building new knowledge as well as a resource for other teachers and learners. By offering structures for inquiry teaching and learning, asynchronous community-building is occurring with teachers/learners being able to draw upon and share their own applications of inquiry-based teaching. The Inquiry Page, then, becomes the nexus between theory and application. It emerges as a “portal” for the scientist-fellow, teacher, and students in the classroom; facilitates communication between the teacher/scientist team and other educators both at the school and in the larger education community; supports inquiry-based teaching in the real world of the classroom; and nurtures the development and professional growth of the teacher and scientist/fellow by engaging in reflective educational theory and practice.

*The EdGrid GK-12 Fellowship Program supports annual teaching fellowships for graduate student scientists from the University of Illinois, Urbana-Champaign and is administered by the National Center for Supercomputing Applications.

Evaluation methods: The GK-12 Evaluation team is adopting a situated evaluation approach to gathering data at each high school site, using online formative and summative evaluations of students, teachers, and fellows in addition to observation, videotaping, and interviews. Teacher and fellow reflections are thus captured quantitatively and qualitatively. Artifact/products of students, teachers, and fellows are reviewed. Key to the evaluation process is an understanding of and sensitivity to each site’s context and dynamics. Of particular interest for the Inquiry Page is identifying its uses and utility, and this is determined by units created and interviews with teachers/fellows.

Sites: Site 1 is located in a suburb of a large city. It was formed to offer alternative (i.e., vocational) education for students grades 10-12 to supplement their regular high school curriculum. Site 2 has approximately 2,325 students and offers a traditional college-preparatory high school curriculum. It is located in a comparatively wealthy cosmopolitan suburb of a large city. Site 3 has approximately 1600 students and is located in an industrial district. The school offers a diverse curriculum that includes two “academies” specializing in medical science or math/engineering/information technology for accelerated students. Site 4 is located in a twin-city that is home to a large university. It offers a traditional college-preparatory curriculum.

The Inquiry Page: The Inquiry Page (www.inquiry.uiuc.edu) is a five-year-old project developed initially as a supportive tool for teacher development by Dr. Bertram Bruce at the
University of Illinois, Urbana Champaign. It has since evolved into a web-based tool and collaboratory to facilitate inquiry-based learning and teaching within much broader contexts. Evaluators, teachers, and scientist-fellows participating in the GK-12 Program have used the Inquiry Page, identifying its utility for their needs.

Facilitating Inquiry in Teaching/Learning: Each site differed in its adoption of the Inquiry Page. Two of the fellows found it unusable in their specific classrooms: one fellow noted teacher disinterest in learning methodologies or new technology, while another fellow noted a sense of it not being relevant to his/her teachers’ subject/learning context. Each of the other fellows, however, employed the Inquiry Page as (1) a lesson planning tool for teachers, including tutorials, resources, and personal reflections in their role as fellow/teacher in the classroom; (2) an archive for their own work and reflections on their particular GK-12 site, including site-specific resources; and (3) as a way to more deeply understand inquiry-based learning and engage in a “co-learner” relationship with their teacher. The model identified by the fellows in their mid-year evaluation as most successful was one in which the teacher and fellow worked collaboratively in teaching/learning. The Inquiry Page facilitated this type of relationship in and out of the classroom; with units serving as new points of communication with educators both within and outside of the individual district/sites. The GK-12 Evaluation team initially thought the Inquiry Page could be used to document their observations; however, they found that it was more useful as an artifact of the teacher/fellow teams’ evolving teaching models. Unexpectedly, the Inquiry Page has been used as a presentation tool with the units being demonstrated at NSTE, NABT, TeachIT, and various district meetings. Perhaps most interesting is the Inquiry Page’s role in introducing inquiry-based learning to the fellow/scientists and giving a “name” to what teachers were already doing or wanted to do in the classroom. Although all had heard the term, and had an intuitive sense of what it meant, it was during the process of creating units that points of recognition and understanding of real-world application occurred. Essential features of classroom inquiry in the sciences as defined by the National Research Council are identifiable at each of the sites; particularly at one site, where the scientist fellow/teacher/students are generating new research questions that are being incorporated into the scientist-fellow’s dissertation work. The Inquiry Page is bridging the gap between education pedagogy and real-world applications in the classroom, creating a framework for scientists and teachers to collaborate—to the benefit of both.

Abstract: As one of the research university teams participating in the National Science Foundation (NSF) GK-12 Fellowship Program*, site educators and scientists are realizing collaborative, technology-rich learning environments that have implications for teacher development, administrative planning for technology and curriculum, and the professional growth of young scientists. Scientist fellows in biology, chemistry, mathematics, computer and information science are strategically partnering with high school teachers and administrators, integrating the use of problem-based learning (PBL), scientific visualization, and informatics in science and mathematics education. Initial data thus collected by the GK-12 Evaluation Team of six teams at four sites across Illinois offer context and contrast in professional development, support, planning, and implementation. This paper addresses the evolving collaborations between administration strategists, the science and mathematic teachers, and scientist-fellows at these sites and the implications for success.

*The EdGRID GK 12 Fellowship Program supports annual teaching fellowships for graduate student scientists from the University of Illinois, Urbana-Champaign and is administered by the National Center for Supercomputing Applications.

Evaluation methods: The GK-12 Evaluation team is adopting a situated evaluation approach to gathering data at each high school site, using online formative and summative evaluations of students, teachers, and fellows in addition to observation, videotaping, and interviews. Teacher and Fellow reflections are thus captured quantitatively and qualitatively. Artifact/products of students, teachers, and fellows are reviewed. Key to the evaluation process is an understanding of and sensitivity to each site’s context and dynamics.

Sites: Site 1 is located in a suburb of a large city. It was formed to offer alternative (i.e. vocational) education for students grades 10-12 to supplement their regular high school curriculum. Site 2 has approximately 2,325 students and offers a traditional college-preparatory high school curriculum. It is located in a comparatively wealthy cosmopolitan suburb of a large city. Site 3 has approximately 1600 students and is located in an industrial district. The school offers a diverse curriculum that includes two “academies” specializing in medical science or math/engineering/information technology for accelerated students. Site 4 is located in a twin-city that is home to a large university. It offers a traditional college-preparatory curriculum.

Roles and relationships thus identified in the GK-12 Project partnerships that are addressed here are that of the (1) educators and fellows as teachers/learners and (2) administrative decision-makers and their role in planning and support.

Educator and Fellow Relationship: Each site differed in the roles the teachers and the fellows adopted. The model identified by the fellows in their mid-year evaluation as
successful, is one in which the teacher and fellow are peers, collaboratively learning and teaching. This model allows for the educator and fellow to both be learners and teachers; and, in one problem-based learning (PBL) environment, for the students to be "teachers." Initial data indicates that successful partnerships are less rigid, allowing for role boundaries to change and accommodate professional growth. Math and science visualization tools, course-specific technology, and computers were real-world points for collaborative learning by both the teachers and fellows.

**Administration's Role in Planning and Support:** The sites differed drastically in the role that administration has played in both implementing technology in the science curriculum, and the support it offers its educators. For example, at one site, the principal was not aware of who the scientist-fellow was or what s/he was doing there, meeting only once during an eight-month period. This colored the relationship the teacher had with the fellow, and appeared to be a block to introducing new ways to integrate computer-based learning (CBL) and PBL. Another site lacked communication avenues between the teacher, the administration, and the fellow, with the administration adopting a *laissez-faire* approach. This put the responsibility for implementing CBL and PBL in the classroom on the shoulders of the scientist-fellow with little guidance from the administration.

These sites contrast with one site where the administrative team has taken a pro-active role both in district-wide strategic planning and long-term support. The district is invested in learning how the GK-12 program fits into the professional development models that already exist; is growing a teacher-to-teacher mentoring program, building a culture of continued professional growth; sees data gathering as critical to informing the decision-making process; and actively seeks funding to accommodate the needs of a technology-rich science curriculum. The administration genuinely solicits teachers' input, meeting formally and informally with teachers and fellows; and sends teachers to national conferences (i.e., NABT, NSTE, & NCTM). In practical terms, the administration demonstrates their support by arranging schedules to allow teachers "extra" time in order to plan and become comfortable with new digital tools in order to integrate PBL methods.

ABSTRACT
Adaptive Hypermedia Systems are capable of delivering personalized learning content to learners across the WWW. Learning Environments provide interfaces and support services to aid tutors in course construction and aid learners in navigating those courses. However, most Learning Environments deliver content sourced from local repositories. This content tends not to offer adaptive features that Adaptive Hypermedia Systems are capable of delivering. Adaptive Hypermedia Systems, which are generally Web-based, could be viewed as personalized content services, with the capacity to deliver content to many Learning Environments. However, in order to co-ordinate the correct cooperation of the Adaptive Hypermedia Service and the Learning Environment knowledge and information models need to be exchanged, e.g. learner profile, assessment information, pedagogical constraints. There does not exist, however, a standardized mechanism for integrating Adaptive Hypermedia Services with Learning Environments.

In this paper the requirements for the generic integration of Adaptive Hypermedia Services with Open Learning Environments is explored. The main aim of such integration should be to work within a framework that allows for minimal impact on current Adaptive Hypermedia Services and Learning Environment implementations, while allowing for maximum standards-based interworking. This paper proposes an architecture and interface to support the collaboration of Adaptive Hypermedia Service and Learning Environments.

1. INTRODUCTION
In the current educational electronic landscape the most prevalent architecture for delivering content to a learner is via a Learning Environment. These environments (sometimes referred to Learner Management Systems or Courseware Support Systems [13]) holds all the content centrally and delivers it to the learner over the Internet, typically via web browser technology.

Developers and publishers of content must design their content for a particular Learning Environment (LE), restricting the reuse and marketability of that content. Typically this restriction is based on the local repository used by the LE or the content management services offered by the LE, e.g. TopClass, WebCT. Advances are being made in the packaging of content to facilitate reuse and integration of content into different Learning Environments (see Section 4.3 IMS Content Packaging), but these advances are concerned currently with static content. If developers of content wish to produce material with complex play rules or high levels of learner interaction they are restricted to the facilities provided by individual Learning Environments.

An alternative is to produce stand alone Adaptive Hypermedia Services (AHS) which are capable of providing these rich play rules and learner interaction. These services would reside as separate servers on the Internet. The benefit in integrating LEs and AHSs lies in combining the strengths of both systems. LEs provide administration and support facilities, while AHSs provide better quality education, personalization and pedagogical control to learners.

This paper explores how current open specifications may be used to achieve seamless integration between such AHSs and LEs. Section 2 discusses the Learning Environments requirements which an AHS should meet to integrate with the LE. In section 3 Adaptive Hypermedia Services and their information requirements are discussed. Section 4 deals with current standards and specifications which may be utilized and enhanced to enable integration between LEs and AHSs. Section 5 continues to propose an architecture for this integration. In section 6 the implementation of an example system is discussed. Section 7 provides a summary of the aspects discussed in the paper.

2. LEARNING ENVIRONMENTS
Most current Learning Environments [3] integrate and store all content to be delivered to learners into a proprietary data storage format. Publishers of content have to author their content for a particular LEs proprietary format or import it into that format. For many of the LEs the content is static, interspersed with assessments. Some LEs use the learner's performance in the assessment information as a control mechanism to determine the flow of the content. Few LEs, however, modify the flow of content through monitoring the learner's progress through non-assessment material, i.e. they do not generally take time factors or multiple visits to a piece of content into account. Lack of
standardization on how these content flow mechanisms are represented leaves the publisher of content with a problem — they can either author content with complex play rules for a specific LE and risk making it unfeasible to export that content to other LEs or they can author static content that is easily exported between different LEs with no play rules.

This static approach to the content leads to a ‘one size fits all’ approach, where the learner’s are all presented with the same course content and assessments. The main advantage that LEs offer over the classroom situation is that the learner can set a pace that best suits their learning. In academic and commercial learning situations it is rarely preferable that the learner decides the pace at which they digest the material fully, as constraints such as formal examinations, which tend to occur at fixed points in time, dictate when material needs to be learned by.

Some LEs offer facilities to include remote content, i.e. the content resides on a remote (probably HTTP) server. These LE do not, however, offer standards-based mechanisms to the remote server to request or pass information back to the LE. This facility is usually used to include static content from a remote server because for a remote server to provide adapted content requires integration with a proprietary communications protocol.

From a pedagogical perspective LEs do not offer many services to assist the learner in how they learn. They do tend to offer good management facilities to the course coordinator, such as —

- Learner and class management
- Course assembly and publishing
- Learner tracking across courses
- Summative assessment information

The Learning Environment, therefore, can offer learner management facilities to the Adaptive Hypermedia Services.

2.1 Requirements of the Learning Environment

2.1.1 Control Information

The Learning Environment needs to be informed of when the learner pauses their learning within the Adaptive Hypermedia Service. This control information may be used by the LE to determine whether the learner should be launched back into the AHS upon logging into the LE next time. Some LEs operate on a free navigation system, where the learner can browse to any section within the course and the course is only considered complete when the learner has received an assessment for each section.

LEs using a content management API (see 4.4 Content Interworking below), such as that in ADL SCORM v1.1 [15] have access to the required data model element cmi.core.lesson_status to indicate whether the content has been completed. The AHS can cater for learners that have completed the assessment aspects associated with their required objectives and received an assessment score from the AHS, but have not completed their optional objectives yet by setting the value of this data model element to incomplete (which is part of the restricted vocabulary for this element).

2.1.2 Assessment Information

Learning Environments tend to gather assessment information on the course section level. As different content may return assessment information in a variety of ways the LE often requires the assessment score to be normalized. The AHS may have to return assessment information in a particular format.

3. ADAPTIVE HYPERMEDIA SERVICES

Adaptive Hypermedia Services allow hypermedia content to be delivered to learners in an adaptive manner. In order to be called a service the AHS must facilitate ease of integration in order that learners are able to seamlessly launch, through any LE, and use the AHSs adaptive content. This process, as far as the learner’s interaction with the LE is concerned, should appear no different from regular static content. It may be the case that the learner is studying content from both static and adaptive sources to achieve a learning objective. The AHS may, therefore, be called as part of a larger course.

3.1 Requirements of an Adaptive Hypermedia Service

AHS information requirements depend on the type of adaptivity it is providing and on whether it insists on gathering this information for itself. The AHS may require learner information and assessment information from the Learning Environment in order to successfully produce content specific to the learner’s and tutor’s requirements.

3.1.1 Objectives

An Adaptive Hypermedia Service may be capable of delivering more content than the tutor requires the learner to study in order to achieve particular learning objectives within a curriculum. It is necessary that the AHS be able to determine what the required learning objectives are before generating a body of content for the learner.

Learners tend to prefer systems where they maintain control of their learning [10]. If learners have total control over their objectives they may ignore elements of the content that are required within the curriculum. To cater for both approaches the AHS could support two levels of objectives – required and optional. When the learner has completed (and been successfully assessed on) all of the required learning objectives set by the tutor they are considered to have completed the AHS courseware. They may have selected optional objectives which are of interest to them, or that they feel aid their learning. They may continue to interact with the AHS until all of these objectives are also completed.

This two-tiered approach to objectives gives the learner control of their learning, while assuring the tutor that they have, at least, covered the core objectives.
3.1.2 Learner Information

There is a large amount of information that could be passed between the Learning Environment and the Adaptive Hypermedia Service regarding the learner. The main difficulty in passing this information is to represent it in a way that all AHSs and LEs can understand. Candidate specifications include PAPI [12] and IMS Learner Information Packaging (LIP). As yet neither of these specifications deal with the representation of pedagogical aspects of the learner, such as learning styles, prior knowledge or life long learning goals (i.e. career path). Even if there was a recognized standard for passing this information there is no common vocabulary to which AHSs could adhere to process the information. Individual AHSs will however have their own mechanisms and vocabularies for storing pertinent learner information.

The primary requirement of the LE with respect to learner information is, therefore, that they can uniquely identify learners within the AHS. Globally unique identifiers of any nature is a non-trivial problem. The approach suggested here is similar to most ‘solutions’ to this problem – if the LE is running from a given URL and has internal identifiers for learners, then the AHS could use a combination of the LE’s URL and internal learner identifier to produce an identifier for internal AHS use. This approach does have one major shortcoming – if the learner is enrolled in a number of LEs the AHS has no mechanism to recognize that the learner may have accessed it from another LE. IMS’s LIP Information Model [9] document discusses this issue concluding that the source of the information record is responsible for the uniqueness of the learner identifier and that the ‘uniqueness of the source (the LE) label is outside of the scope of this specification’.

Another issue with which the AHS may have to contend is whether the learner is already engaged in another course which also utilizes this AHS. If they are the AHS will need to differentiate between the two by asking the LE for a section identifier of some description. This will allow the AHS to use the correct set of objectives required and optional for the learner.

If the LE cannot reasonably be asked to pass pedagogical information about the learner to the AHS then it is the responsibility of the AHS to pre-test the learner to acquire this information. This pre-test is used to determine the learners competencies (e.g. prior knowledge) and learning preferences (e.g. learning styles and display preferences). This is where the importance of identifying the learner comes to the fore. If we can identify the learner then if they re-enter the AHS we do not need to perform a full pre-test as some of the information determined in previous tests is domain independent, such as some learning preferences. Assessment information may also be used to aid the determination of the learner’s competencies.

3.1.3 Assessment Information

As mentioned above in 2.1 Requirements of the Learning Environment LEs generally require summative assessment information from each section of a course. In [14] one of the sixteen design guidelines for courseware is ‘specifying entry level learner competencies’ for the content. Within the Adaptive Hypermedia Service, however, there are no fixed competencies required as the AHS delivers content that best suits the learner’s competencies. The AHS must, first of all, determine these competencies.

The AHS can use assessment information to determine at what level to pitch the competency pre-testing of the learner. If the AHS can ask the LE for the assessment information of both the learner and their peers for sections of the course completed then it is possible for the AHS to determine how the learner is performing in relation to his peers and thus gauge the difficulty of the pre-test. Assessments should not be too difficult at the beginning of the course or they will discourage the learner [6]. It is also undesirable for prior knowledge assessments to be too easy for the learner as the assessing of the learners prior knowledge may take longer, thus increasing the time before the learner feels they are learning new (relevant) material.

The aim of using previous assessment information is to determine the point within a difficulty scale at which the pre-testing should begin. At this point certain assumptions may be made about the learners prior knowledge. The task of the pre-test is to confirm these assumptions and determine if the learner has further (non-assumed) prior knowledge that is pertinent to their objectives and the content the AHS will be presenting. Ideally this start point should be positioned just below where the learner’s competencies actually lie, so as to confirm the learner possesses these competencies and determine where the boundary of their competencies lies.

4. STANDARDS AND SPECIFICATIONS

4.1 IMS Learner Information Package

The IMS Learner Information Package [9] specification addresses interoperability between internet-based learner information systems. Learner information concerns Learners (individual or group) or Producers (creators, providers or vendors). LIP includes facilities for the Learner to determine which aspects of their information are sharable with other systems. LIP has been designed with four basic requirements in mind – Distributed Information, Scalability, Privacy and Data Protection and Flexibility and External References.

The last requirement is described in [9] as Learner information includes many constructs, such as learning objectives and learning history, which are in practice represented by different structures in different contexts. Learner information data models must be flexible enough to accommodate this need. An external reference may, in the future, be used by both Learning Environments and Adaptive Hypermedia Services to share learning objectives and learning style information. IMS LIP v1.0 is currently available as a public draft.

4.2 PAPI

PAPI [12] is the IEEE Public and Private Information Specification which is a standard format for the representation and communication of student profiles. The purpose of the specification is to allow the creation of student records which can be communicated between educational systems over the lifetime of a learner.

The PAPI specification is divided into four areas – Personal Information, Preference Information, Performance Information and Portfolio Information and it also incorporates the Dublin Core metadata element set. The information used to construct the user profile is inferred by the system, directly input by the user or is constructed by the user and system in collaboration. PAPI also intends to address the privacy and security issues involved in the storage and communication of user profile [3].
4.3 IMS Content Packaging
IMS Content Packaging is an interoperability specification to allow content creation tools, learning management systems and run-time environments to share content in a standardized set of structures. Version 1.1 of the specification is focused on defining interoperability between systems that wish to import, export, aggregate, and disaggregate packages of content [8].

The primary goal of the IMS Content Packaging specification is to provide a mechanism which, once implemented by producers and vendors, will allow content to be exported between systems with the minimum of effort. Version 1.1 of this specification is currently available as a public draft.

4.4 Content Interworking
The Content Interworking API was initially developed as part of the AICC CMI, more recently developed as part of ADL SCORM and the University for Industry Content Interworking Specification.

It is proposed that the IMS Content Management group will adopt the Content Interworking API as specified in the AICC CMI specification v3.0.1 and currently under implementation by the ADL [15] and by the University for Industry [16].

4.4.1 Aviation Industry CBT Committee Computer Managed Instruction Guidelines
The AICC guidelines [1] provide a method for seamless data flow between different computer based training (CBT) lessons and Computer Managed Instruction (CMI) systems, between different CMI systems, and from CBT lessons created with different authoring systems to a common data store and off-the-shelf analysis tools.

The driving force behind the development of the AICC CMI was to allow content developed by different authors to be used with any CMI system that supports the guidelines. To this end an API was designed that allowed the content to connect to the CMI system. The API principally facilitates the getting and setting of data in the CMI systems data model.

There are two aspects of the AICC approach to enabling interoperability of CMI systems with different CBT systems –

1. Lesson launch: The CMI should have a standard approach to CBT lesson initiation, and
2. Communication: The CMI should have a standard approach to providing information to the CBT lessons, and receiving information from the CBT lessons.

4.4.2 Advanced Distributed Learning SCORM
ADL SCORM [15] (Sharable Courseware Object Reference Model) is based on the AICC CMI guidelines. ADL was established with the purpose of developing a (US) Department of Defense wide strategy for using learning and information technologies to modernize education and training. Version 1 of SCORM defines a reference model to facilitate the interworking of Learning Management Systems (LMS) and content providers material. (LMS is used in the SCORM documentation in place of CMI). The SCORM is based directly on the runtime environment.

The ADL collaborated with AICC members and participants to develop a common Launch and API specification.

4.4.3 IMS Content Management
The IMS Content Management [7] specification is currently under development. The goal of the IMS Content Management specification is to establish a standard for data interchange and communication between instructional content and run-time environments. This specification should provide cost-effective content interoperability for platform, tool and content developers when implementing the specification in their products.

It is proposed that the Content Interworking API to be used within IMS Content Management will also be based on AICC SME guidelines and ADL SCORM.

5. ARCHITECTURE
The mechanisms required of an open architecture for integrating Adaptive Hypermedia Services with Learning Environments are standards-based approaches to –

- Importing the location of the AHS into the LE
- Launching the AHS from the LE
- Communicating between the AHS and LE

A commonly understood data model is also required to facilitate the communication of learner information, learning objectives and assessment information.

5.1 Importing the AHS location into the LE
IMS Content Packaging will provide a mechanism for static content to be integrated into a Learning Environment. By importing content as part of an IMS Content Packaging archive, with an XML manifest included, it is envisaged that the content can be automatically installed into the LE's content repository.

With Adaptive Hypermedia Services the content is not shipped in discrete units of material. The AHS is a remote service that the LE has an entry point to. As the LE, such as Microsoft's LRN [11], may already have an IMS Content Packaging import facility a reasonable approach would be to utilize this and enhance it to allow for the importing of the location of the AHS as part of an IMS Content Package. This could be imported into a LE in a similar way to static content. The manifest would describe the adaptive service and also contain a URL which the LE would use to launch the service.
Another consideration on the importing of the Content Package is that the learning objectives that the AHS is capable of achieving should also be imported into the LE. Provision should be given to the tutor to specify which learning objectives they would like the learners to achieve within the AHS.

5.2 Launching the AHS from the LE

When the Adaptive Hypermedia Service is launched from the Learning Environment the content it delivers will be coming from a different server than the Learning Environment. The AHS firstly initializes its connection with the LE. The AHS needs to then determine if the learner has been engaged in this course component before. If they have then it can rebuild the adaptive course component for the learner from a snapshot taken prior to the content being paused.

If the learner has not utilized this adaptive course component before then the AHS must determine two things – what the learning objectives are for the learner and whether the learner has been engaged in any course component offered by the AHS before. The learning objectives are used by the AHS to determine the required objectives for the content it is about to deliver. Optional objectives can also be offered based on the required objectives and the learner’s prior knowledge. If the learner has used the AHS before from the launching LE this will alleviate the necessity to determine the learning style and possibly some prior knowledge aspects of the learner. It will still be necessary to pre-test the learner as their assumed prior knowledge may have degraded with time and/or they may have learned further relevant knowledge.

5.3 Communication between the AHS and the LE

Communication between the Adaptive Hypermedia Service and the Learning Environment can be achieved using the SCORM Runtime Communication API as used in SCORM v1.1. A subtle modification to the HTML frame layout is required at the AHS to enable calls to API functions residing on the LE from AHS content. The actual API calls used are the same as those used in SCORM v1.1 as the API is designed to get and set values that are separately defined by an external data model [15].

Figure 1. The AHS accessing the LE data model using the Content Interworking API

The remote AHS calls the Content Interworking API to access the data model on the LE using the following process –

a) The learning content (right browser frame) and JavaScript API (left browser frame, hidden) are delivered to the learner’s browser.

b) An API function, in the left hand API frame, (e.g. LMSGetValue("cmi.core.lesson_status")) is called from the content frame.

c) The API frame communicates the request to the Learning Environment.

d) The Learning Environment returns the value (in this case of cmi.core.lesson_status) to the API Frame.

e) The function returns the value to content frame.

f) The value may be passed back to the Adaptive Hypermedia Service.

5.3.1 Common Data Model

The data model required for AHS/LE interaction is similar to that proposed in SCORM v1.1. The key requirements of the data model for this interaction are –

- Learning Environment identifier (to uniquely identify the LE, possibly it’s URL).
- Learner identifier (to uniquely identify a learner from a LE).
- Section identifier (to determine, using the elements above, whether the student has attempted this content in the AHS before).
- Section status (completed, incomplete, attempted etc.)
- Section objectives (allows the AHS to query the LE for the learning objectives the tutor wishes learners to achieve).
- Score information (across all sections, for the learner and averages for all enrolled students).
- Score range (the LE may not use percentile scoring and the AHS may need to normalize the scores).

The number of SCORM data model elements has been significantly reduced between version 1.0 and version 1.1. This reduction was to aid harmonization between independent developments of the Content Interworking API (see 4.4 Content Interworking), i.e. many groups where using the same API, but had subtly different data models. Many of the optional elements defined in SCORM v1.0 had not been implemented by other consortia. A complete list of the data model changes between SCORM versions is available [15].

Most of the required data model elements for AHS/LE interaction already exist in some guise in the CMI data model used in SCORM v1.1. Learner identifier, section identifier, section status, section objectives and score range all have equivalents. The LE identifier and summative score information is not available within the data model.
6. IMPLEMENTATION
The mechanism for interfacing LEs and AHSs described in this paper has been implemented using Fretwell-Downing Education’s LE [5] and Trinity College, Dublin’s AHS [3] within the European Commission funded EASEL [4] project. The data model used is based on SCORM v1.1 [15] with the addition of LE identifier and summative score elements. Using this model it is possible for the AHS and LE to interact, sharing information about the learner including, but not limited to –

- Learner Identification
- Interface Preferences
- Pedagogical Preferences
- Performance Information

The first piece of information that is requested by the AHS from the LE is the LE identifier. This should be unique, possibly URI based, and allows the AHS to contextualize all further communications. For example, when it asks for the learner’s identification it might assume that this identifier is unique within the LE, but not across other Learning Environments.

Learner identification enables the AHS to ascertain if the learner has visited the service before and if they have determine whether it is necessary to pre-test them. For example, if the learner completed another course within the AHS already then it should have pedagogical information that is sufficient to adapt to the learners requirements and abilities. If the AHS has no information, or no appropriate information about the learner then it is necessary to pre-test.

Prior to administering the pre-test the AHS can query the LE for assessment scores for any material the learner has attempted in the course (assuming the AHS is a component of a larger course) and also request the assessment scores for the learner’s peers in the course. These values are returned in as normalized values in a range specified by the LE. Using this information the AHS can determine the difficulty at which to set the pre-test, if it has multiple pre-tests aimed at increasing levels of knowledge. Such a pre-test can be used to determine the prior knowledge about a domain before generating the personalized course.

Other extensions that may be made to the LEs data model could cater for – Cultural Background, Preferences & Learning Culture, Communication Style and Needs, Cognitive and Learning Style, Prior Knowledge & Expertise, Communication Style & Needs, Learning History and Objectives and Goals.

The primary constraint to adding these complex elements within the data model is that of a commonly understood and accepted vocabulary to describe each extension. This is why the approach taken within EASEL was to allow the Adaptive Hypermedia Service to use a proprietary vocabulary internally, but to return assessment information.

Assessment information is returned to the LE using the normalized range mentioned above. This allows the AHS to inform the LE how the learner has performed in any assessments they have completed, but this is only a summative score for all assessments completed in the AHS.

The IMS Question and Test specification was investigated as a candidate for richer communication of learner assessment results, but the uncertainty as to whether an individual assessment would be present in a personalized course meant the information for different learners might be inconsistent.

7. SUMMARY
This paper has described a mechanism for integrating Adaptive Hypermedia Services and Learning Environments and illustrated this approach with an implementation from the EASEL project. The mechanism described is based in current and emerging learning technology specifications and requires minimal modifications to LEs that utilize these specifications for their intended purposes.

By enabling AHSs to be successfully integrated into LEs this mechanism provides the potential for more learners to avail of the pedagogical benefits possible using customized adaptive content.

8. ACKNOWLEDGMENTS
This research is partially funded by the European Commission under the auspices of the EASEL (Educator Access to Services in the Electronic Landscape) [4] project. The EASEL project’s goal is to explore technologies which can be brought together to offer course constructors an environment in which they can readily combine existing learning objects to create new online educational offerings. Current proprietary Adaptive Hypermedia Services tend to restrict this kind of integration. As part of EASEL the research conducted will be used to integrate Adaptive Hypermedia Systems into Learning Environments which are based on current WWW educational standards.

9. REFERENCES

Abstract: Contemporary humanities students tend to think that human expression occurs in a vacuum. They do not understand that human expression in any given time period is produced by, and remarks, the zeitgeist of that period while at the same time exhibiting characteristics of human nature that have existed since the beginning of human history. Humanities students need connection among disciplines, among cultural forces, with history, and to themselves. This paper illustrates how technology and Internet access can change the roles of instructor and learner alike, as well as improve the pattern of learning behaviors in a classroom. Through online resources students can gain a better sense of zeitgeist in a given culture at a given time; at the same time they can recognize the universality of the human experience. The Internet and Web page design tools also provide opportunities for students to conduct research themselves and to publish their research efforts in new and engaging ways.

Introduction

Because of movements toward specialization and compartmentalization in education through the course of the twentieth century, many of my students have a fragmented view of the world. To some extent, they have been taught art, literature, and music, but they do not understand any historic or contemporary connections among these disciplines, nor do they recognize relationships among these and science, technology, religion, politics, and mathematics. Thus, they tend to think that human expression occurs in a vacuum. They do not understand that human expression in any given time period is produced by, and remarks, the zeitgeist of that time period. Human expression, however, also exhibits those characteristics of human nature that have existed both before and since the beginning of recorded history. Students in the humanities really need connection among disciplines, among cultural forces, with history, and to themselves. With this rationale in mind, and after a brief overview of my evolving pedagogical method, I seek in this presentation to illustrate how technology and Internet access can change the roles of instructor and learner alike, as well as improve the pattern of learning behaviors in a classroom (Dalgaro, 2001). Technology can provide opportunities to interweave resources so that students can gain a better sense of zeitgeist in a given culture at a given time; at the same time they can recognize the universality of the human experience. The Internet and Web page design tools also provide opportunities for students to conduct research themselves and to publish their research efforts in new and engaging ways.

Pedagogical Methods

Before discussing interweaving strategies with an example text, I must comment on my changing method of teaching the course from which the example comes. The course is pre-modern world literature. I used to teach this course in a lecture and class
discussion pattern, but in recent years I have come to recognize that students learn best when they are active collaborative learners (Anstendig, Meyer, & Driver, 1998; Barab, Thomas, & Merrill, 2001; Lu, Zhu, & Stokes, 2000; Scheurman, 1997) and that "[t]he internalization of capabilities that constitutes learning is . . . as much a social as an individual cognitive phenomenon" (Borthick, 2001). Therefore, I first modified the course by having my students do research and oral presentations on works during the course of the semester (Mintz, 1998). However, I realized that this alteration was not sufficient to change the learning patterns in the class and to engage and enable my students on the path to learning. Thus, I decided to have my students prepare for class by reading the assigned text and answering directed questions that I now place on the course calendar in WebCT. The questions relate to structure, themes, archetypes, metaphors, etc., of that text in relation to earlier works as well as to contemporary culture, and they build upon each other through the course of the semester. At the beginning of class, I give a daily quiz to ensure that students have read the work. Then students give their scheduled presentations on that day's text. After these presentations, students break up into groups, physically moving their chairs to face each other and thus altering the monolithic, instructor-centered structure of the classroom. They share their responses to the online questions and decide on the best answers to each question regarding the work. During this time I wander through the classroom, listening to group exchanges, asking more guided questions to help them "flesh out" their better responses, and expanding upon their insights by making reference to historical information or to past texts with which they are now familiar. Finally the class comes together to answer the questions, and, using Internet sources to supplement the discussion, I reinforce those answers with the information that I once imparted through lecture. Frequently, however, students end up telling me what I would have told them in a lecture. In other words, they discover and own the knowledge. Also, quieter students respond very positively to this format because it tends to give them voices; the quiet student learns that if I call on him or her to answer when the class is working together, then I have heard his or her answer and thought it a good one.

As an illustration of effective Internet use, in this presentation I will employ the medieval play, Everyman, as an example. To instill in my students an understanding of the medieval world view vis-à-vis the play, I provide links to sites in both WebCT as an accompaniment to the questions and on the online syllabus that is produced in FrontPage and linked from my home page. For religious, political, economic, and other reasons, the common medieval European was encouraged to think of his station in life as an act of God's will. In his relatively harsh world he was encouraged to focus on the afterlife and on the purgation of sin in this life in order to avoid the harsh judgment of God. To show that medieval architecture reflected this thinking by drawing the eye upward to heaven and to beauty at great heights, I furnish links to the cathedral at Chartres. To illustrate the fact that art production and the transcription of religious texts were considered by many as acts of spiritual devotion and thus were quite elaborate, I provide links to medieval art and to illuminated manuscripts. I also furnish links to audio sources of medieval music including Gregorian chants, as well as to sites that treat medieval quotidian life and demonstrate not only cultural zeitgeist but also how very human and like us the medieval Europeans were. My students view these sites on their own, but by the time we revisit them together in class, students can really begin to grasp how these different means of
expression and cultural behaviors, as well as universal behaviors, are tied together. In
addition, in order to help them to understand the dynamic quality of the English language
especially during the rise of the printing press, I link to an early printing of Everyman, in
which ‘u’ and ‘v’ were used each others’ places when compared to modern usage. This
recognition serves to alter students’ misguided perspectives that English has historically
been static.

Having witnessed the positive effects of Internet use in teaching this world
literature course, I then decided to let my students use the Web to share some aspects of
what they had learned. In lieu of the traditional research assignment, in recent semesters
I have given my students the option of designing research Web sites. Since both
traditional essays and research sites were assessed by Clayton College and State
University’s established writing criteria, those who chose traditional essays were by no
means penalized for their choice. Because of difficulties with hypertext readability, the
only difference in the assignment was that the traditional essays were to be five to seven
pages in length, while online essays were to be approximately five pages in length. As
examples provided during this conference presentation showed, students who made the
research site choice found great benefits in publishing on the Web. Those benefits
included learning to use established criteria for authoritative Web sites; reasoning out for
themselves how interdisciplinary forces were at work in a culture by using visual, audio,
and textual sources; linking directly to sources from their sites and even within the text of
their essays; and using their own creativity in site design. There were also problem areas.
Those included problems with coherence in the multimedia environment and with
transference of text from one application to another. For example, many HTML editors
do not permit or recognize indents, so proper paragraphs and MLA “Works Cited” lists
cannot be composed in them nor pasted into them. Students also ran into problems with
changing or alternative rules for citation of sources on the Internet. In addition, some
students lacked Web design experience, and their sites verified this lack. However, a few
of my novice designers produced the most remarkable sites with well-composed essays.

Conclusion

My methods in this course are still progressing toward a those that facilitate the
best learning for the student, but the rate of student information retention is markedly
higher, as is the positive awareness of learning among students; both superior anecdotal
exam evidence and more positive student responses to questionnaires in my classes
versus those in the traditionally taught courses indicate these improvements. Students
utilize and recognize their knowledge and empowerment.

As I am discovering, from one semester to the next, authoritative sources for the
humanities are appearing at an exponential rate on the Internet. Our use of these sources
with innovative teaching strategies can serve to alter the roles of instructors and learners.
This use can serve to enhance our students’ grasp of a work within its cultural zeitgeist; it
can also illustrate more clearly the universality of human characteristics from the
beginning of recorded history. In short, these resources can reconnect our students to the
world around them in encompassing and interdisciplinary ways. In addition, Web
publishing offers new means for students both to synthesize research information and to
compose innovative hypertext essays. The cyber-age is a breakthrough time for new media and new methods of teaching and learning in the humanities.

Tutoring: A Different Background for the Same Role

Antonella Cossetti
Ctu - Center of Technologies for Learning
Università degli Studi di Milano - Italy -
cosetti@ctu.unimi.it

Abstract: In an online course the role of tutor is fundamental and the choice of people to hold this role is very important. In this speech I shall look in detail at the skills, requirements and criteria used to choose the three tutors for the Metodi 99 project (an online course in Methodology and Techniques of Social Research delivered in 1998/1999 by the Ctu of Milan University and Faculty of Political Science), how this choice was made, what strategies were adopted and what results were obtained.

Context

Metodi 99 was organised in two different environments: a Web site for the publication of teaching materials and communication (forum) among professor tutors and students and a First Class software where participants communicated with each other in five spaces (Technical Aid, Mailbox, Secretary, Student Area and a Project Area limited to the project team). Due to some problems relating to the financing of the project, the confirmation immediately preceded the production phase, making it necessary to find an urgent solution to several very important questions only a few days before the start of the course. All these considerations had great repercussions on the tutoring, first and foremost on the choice of people suitable for assuming this role and, second, on the preparation of an appropriate training programme.

Requirements and Role

In an online environment where there is no verbal and physical language to help the dialogue, interpersonal communication techniques are particularly important. As D. Rowntree says “Tutoring an online course is not an easy option. There is a lot to do”. There are many potential roles for the tutor (pedagogical, social, managerial and technical) in different areas (organisational, structural, social and conceptual). In our course the tutor was halfway between professor and students. In the first place, the tutor had to be an “expert in the subject” to provide students with didactic and methodological support, to give advice on materials and clear up any doubts. Secondly, he or she had to possess good “interpersonal skills” to communicate with students in simple terms choosing a suitable register, and with the professor and project team. Lastly, a “reasonably good training in computer skills” was necessary in order to be at ease with the use of a computer, the network and the hardware and software necessary to follow the course.

The tutor’s main task was to look after a group of about twenty students both from a didactic and an organizational point of view, explaining the activities to be carried out, allocating assignments, sending reminders of deadlines and assisting the professor in deciding grades. In terms of time, the role involved at least one hour online every day including weekends.

Choice and Training

Three young people were chosen: Francesca, Marco and Matteo. None of them had ever had experience of tutoring online but all of them were proficient in their subject. Their backgrounds were substantially different and this in turn had a strong influence on their attitude to their new role. Francesca was a political science student at the end of her university studies and working occasionally for her professor; Marco was a recent graduate hoping to do a doctorate but without didactic experience; Matteo (the oldest) had had several teaching and training experiences in the research methodology field. These different “life experiences” also resulted in a
difference in the amount of time available for the course: Matteo’s work kept him occupied, so that he was more distant, at times absent.

A brief training period was arranged to explain the role of the tutor with some documentation and examples of messages sent by the tutors of the previous courses; a session was also held with the course designer who clarified their role and responsibilities. Compensation for the curtailed training period was provided in the form of a tutor co-ordinator with previous experience as the “observer” of an online course and a good knowledge of the role, particularly from a communicative point of view. Together with the course designer, this figure was of vital importance in helping the three tutors to assume their role.

The experience

Before the start of the course, the tutor co-ordinator made contact through a series of messages of a theoretical nature, soliciting reflection on the role of the tutor. A firm but flexible attitude was advocated, in order to provide students with suggestions and encourage them to reflect on the content. In doing this, the students needed to bear in mind that the learning environment was not a traditional one but based on words, where written communication had a set of different rules, characteristics, advantages and limits compared with spoken communication and these could not be ignored (Ong, 1982). When the course started, the three tutors soon realized that theory was very different from practice and they were obliged to face up to a kind of role crisis, with doubts as to their identity as tutors. A theoretical knowledge of their tasks was insufficient and the standard support outlined in the documentation handed out at the start of the course broke down in practice.

All three tutors experienced the same sense of unease and inadequacy and regretted the lack of a longer training period of a more practical nature. Francesca felt the most disoriented: she was strongly tempted to place herself on a level with the students, as she still felt part of this category, rather than assuming more authority.

Reactions differed: whilst Francesca and Marco attempted to look for support in the project team, Matteo tended to remain outside, limiting himself to observing his own class. This did not imply lack of interest in what was going on but the urge to reflect on his role and question his decisions. Of the three tutors, he was, in fact, the one who revealed the greatest maturity from a professional point of view and best covered his role.

In this initial phase of general disorientation, the advice of the tutor co-ordinator proved to be a great help, since he helped solve specific practical problems, making suggestions as to the style of communication to be adopted.

The tutors’ ways of relating to the students were different: Francesca was always more than ready to help, since she felt closer to them in terms of age and experience, and the style of her messages was very colloquial and informal. Marco gave the impression of being stricter and less willing to intervene by encouraging the students to participate and learn, being aware that at university each of them was responsible for his own learning route.

In his view, the tutor should merely provide the tools and students decide whether to take advantage of them or not. Lastly, Matteo proved to be the most formal and detached; certainly the most thoughtful. From him came the most interesting observations on the difficulties encountered: “assuming your role is different from assuming responsibility,” he told us; “it is essential to compare yourself with other people in order to learn how to behave”.

These comments were inspired by the difference between the role of the traditional university assistant and the role of the online tutor. In conclusion, Metodi 99 taught us a great deal about tutoring: it is not easy to find people for this role; a training course before the start of the course is essential; personal background can have a strong influence both on the way the role is approached and on the style of communication.

Abstract: Data are presented on the effects of Animated Agents on multimedia learning environments with specific concerns of split attention and modality effects. The study was a 3 (agent properties: agent only, agent with gestures, no agent) x 3 (picture features: static picture, sudden onset, animation) factorial design with outcome measures of mental load rating scale, a persona rating scale, multiple-choice questions, a matching test, a retention test, and transfer tests involving creative solutions. Overall, there were no split attention or modality effects found with integrating the agent into the display.

KEYWORDS: animated pedagogical agents, multimedia learning, split attention effects, attentional control

Interest in the use of animated pedagogical agents in instructional design involving multimedia in virtual learning environments has increased recently, as new technologies have made them more accessible (Craig, Hu, Marks, & Graesser, 1999; Johnson, Rickel, & Lester, 2000). An animated pedagogical agent is a computerized character (either humanlike or otherwise) that can interact with a user in order to impart some type of information. Because these agents are relatively new, there has been little research into their proper construction, capabilities, use, or limitations.

Animated agents can be seen as logical extensions of the development and customization of new learning interfaces. A line of research conducted by Byron Reeves and Clifford Nass (1996) provides a context for exploring these interfaces. They put forth the basic principles of what they call the "Media equation theory." This model holds that people naturally interact with various forms of media in the same ways they interact with other people. In this context, media can include anything from written text to television to computer programs.

If people tend to anthropomorphize media such as computers and the programs that run on them, there may be real advantages to implementing pedagogical agents in computer interfaces. First, agents increase the bandwidth of communication by the addition of a direct conversational partner, a partner who is potentially capable of showing varied emotional states and patterns of deixis. Second, agents may increase the computer's ability to engage learners and motivate them. Furthermore, appropriate lifelike behaviors make agents appear knowledgeable, attentive to the learner, and helpful (Johnson et al., 2000).

Animated pedagogical agents would seem to provide a challenge to multimedia environments, given the precepts of the cognitive theory of multimedia learning (Moreno & Mayer, 1999). If the agents are integrated as a part of an illustration or animation, their presence could cause split-attention effects (Sweller & Chandler, 1994), or modality effects (Moreno & Mayer, 1999). Modality effects could result from both the agent and learning materials being presented in the visual modality. Such effects might not be overcome entirely by the integration of spoken text with a picture or animation, because learners might concentrate on the agent and ignore the learning materials. What might be required is to direct attention away from the agent who provides the spoken text and toward the appropriate visual materials, for example gesturing by the agent (Johnson et al., 2000) or attention capture within the animation itself (Yantis & Hillstrom, 1994). There is currently evidence that animated pedagogical agents used in virtual learning environments can promote baseline problem solving skills (Johnson et al., 2000; Moreno, 2001; Moreno, Mayer, Spires, & Lester, 2001). However, it is not clear what role agents play in learning environments (Andre et al., 1999).
One of the first studies (Lester, Voerman et al., 1997; Lester, Towns, Fitzgerald, 1999) of animated agents led to what is called the "Persona effect." The claim is that the presence of a lifelike character in the environment has a positive impact on the learner's interactive experience. The study also revealed that more expressive agents are given higher ratings on clarity and utility than the less expressive. Herman the bug was the agent in the study. Participants gave ratings on how helpful Herman was as an aid to their learning experience. However, it is important to note that the Persona effect is silent on whether participants learn more when interacting with agents (Lester, Voerman et al., 1997). It only states that learners enjoy the experience more.

The present study was designed to investigate issues related to attention by manipulating agent properties and features of the pictorial information. Two possibilities present themselves in this context. First, consider the agent, deictic gesture can be used to direct the learner's attention while integrating the animated agent with a picture or animation. Pointing and gesturing are a natural way in which both adults and children attempt to direct attention (Alibali & DiRusso, 1999; Krauss, 1998). Gestures should occur simultaneously or prior to the onset of the speech act that they signify (Mon-et, & Krauss, 1992). A second option is to capture attention by using parts of a picture or animation itself. According to attention research, an excellent way capture attention is by an abrupt onset and motion (Jonides & Yantis, 1988, Yantis & Hillstrom, 1994).

The design was a 3 (agent properties: agent only, agent with gestures, no agent) x 3 (picture features: static picture, sudden onset, animation) factorial. If the use of an agent leads to split attention effects and if these effects are reduced by agent gesture, then we would expect to see the no agent condition > the agent condition < agent with gesture condition. If there were no split attention effect, then no differences would be seen between agent properties. The cognitive theory of multimedia learning would predict that within the picture features animation > static picture. Also, within the picture features sudden onset > static picture if attention capture is sufficient for learning.

**Methods**

**Participants**

Participants in this experiment were 135 students drawn from an undergraduate psychology students at the University of Memphis who volunteered from a pool of participants. This pool consisted of all students taking either of two levels of introductory psychology courses.

**Materials**

The materials for the experiment were of two kinds: computerized materials and pencil and paper. The computerized materials consisted of the visual and narrative information presentation (training section). The pencil and paper materials consisted of a questionnaire for domain knowledge, a test of spatial ability, a mental load rating scale, a persona rating scale, multiple-choice questions, a matching test, a retention test, and transfer tests involving creative solutions.

The computerized materials were created using three different computer application packages. The agent and voice were created using the Microsoft Agent software package (Microsoft, 1998). The multimedia animations were created using Macromedia Flash 3.0 (Macromedia, 1998). These packages were integrated using a Program called Xtrain (Hu, 1998; Hu & Craig, 2000).

Likert-type scales were used for the Persona test and mental load rating. The persona test ranged from 1 to 6 with 1 being extremely enjoyable and 6 being extremely not enjoyable. The scale was similar to those that were described in previous research literature (Johnson et al., 2000; Lester et al., 1997). The mental load rating ranged from 1 to 6 with 1 being extremely easy and 6 being extremely difficult. This subjective rating has been used in previous research as a measure of the cognitive load of a task (Kalyuga, Chandler, & Sweller, 1999; Paas & Van Merrienboer, 1993, 1994).

Participants also received two pencil and paper tests at the outset of the experiment session. Both of these tests were brief and were given prior to the multimedia information presentation. The tests were for domain knowledge and spatial ability.

The test of domain knowledge was a standard screening test used in related research (Mayer & Moreno, 1998; Moreno & Mayer, 1999). This questionnaire consisted of a seven item activity checklist containing statements concerning weather knowledge, with one point added for each checked item and a five level-self assessment from less than average domain knowledge (1) to very much (5). The cut-off criterion adopted was six (out of a maximum 11) in order to be consistent with related research (Mayer, 1997; Mayer & Moreno, 1998; Moreno & Mayer, 1999). The test of spatial ability was a standard paper-
folding task with scores used as a covariate. In the task, participants were simply given twelve minutes to correctly answer as many questions as they could (Bennet, Seashore, & Wesman, 1972).

The information presentation was concerned with the process of lightning formation. These materials have been shown to be effective for achieving learning gains in previous research (Mayer & Moreno, 1998; Moreno & Mayer, 1999). The scenario presented followed a causal path from how a storm front forms to the creation and display of lightning.

The three remaining tests have been used in previous research (Mayer & Moreno, 1998; Moreno & Mayer, 1999). These involved retention, matching, and transfer. The retention test consisted of one question, "Please write down an explanation of how lightning works" (See Appendix D for example). These tests were collected after five minutes. The matching test consisted of four frames with instructions that ask the participants to circle and label the cool moist air, warmer surface, updraft, freezing level, downdraft, gusts of cool wind, stepped leader, and the return stroke. These were collected after three minutes. The test for creative solutions consists of four questions presented one at a time for three minutes each.

In addition to the tests used by Mayer, participants were also presented with a series of six multiple-choice questions requiring a forced choice among four possibilities, one correct with three other foils. These six questions assessed three categories of knowledge (explicit shallow, explicit deep, and implicit deep). The explicit shallow questions focused on the shallow surface level information from the presentation (e.g., The upper portion of the cloud is made up of what?). The explicit deep questions focus on understanding of the concepts what were presented in the information delivery (e.g., When do downdrafts occur?). The Implicit deep questions focus on the application of the underlying concepts to problems that were not focused on in the information delivery (e.g., Why does it get colder right before it rains?).

**Procedure**

The basic procedure was as follows. When the participants first entered the laboratory, they were issued a packet of materials. This packet contained their informed consent, test of domain knowledge, and the test of spatial ability. After these were completed, those eligible for the study (those scoring under half on the domain knowledge test) received instructions for part two of the experiment. They were presented with the information delivery, which took about three minutes. Afterward, they were given the retention question (5 minutes), the Multiple-choice questions (2 minutes), the matching test (3 minutes), and 4 transfer questions (3 minutes each).

**Results and Discussion**

**Persona effect**

A 3 (agent properties: no agent, agent, agent with gesture) x 3 (picture features: picture, onset, motion) ANOVA was performed on the persona data. There was no evidence for a persona effect in this study. There could be several explanations for this. Participants were only exposed to one condition and thus, they had nothing to make a comparison with. If this is the case, a within subject design would be an accurate measure. Also, the agent was displayed for only 180 seconds and that might not have been long enough to produce an effect. Since the persona effect is based on the agent making the learning experience more enjoyable (Johnson et al., 2000), an agent interaction within the learning environment for 180 seconds was probably not enough to produce an effect.

Even though the persona effect (Andre et al., 1999; Lester, Convors et al., 1997) was not significant, a trend can be seen in the data. In the scale, a lower score indicated a more positive rating. The means ratings for the three groups were $M = 3.44$ for no agent present, $M = 3.42$ for agent present, and $M = 3.07$ for agent with gestures with lower numbers indicating a more positive rating. A Cohen's $f$ effect size was calculated for the persona data. These analyses yielded effect size score of .42 in the agent-with-gestures vs. no-agent comparison, and a score of .02 in the agent-only vs. no-agent comparison. This shows a supportive trend for the persona effect.

**Cognitive Load**

A 3 (agent properties: no agent, agent, agent with gesture) x 3 (picture features: picture, onset, motion) ANOVA was performed on the cognitive load data (Paas & Merrienboer, 1993). It yielded a significant effect between the picture features, $F (2,126) = 3.737, p < .05$. A post hoc test performed on the three picture features groups yielded significant differences in perceived comprehension ratings
between the picture condition ($M = 3.62$) and the motion condition ($M = 3.09$), $p < .05$. This finding is in line with the cognitive theory of multimedia learning. It predicts a decrease in the difficulty of comprehension for the motion condition over the picture condition when synchronization of the display is attained that ensures temporal and spatial contiguity (Moreno & Mayer 1999).

Matching

A 3 (agent properties: no agent, agent, agent with gesture) x 3 (picture features: picture, onset, motion) ANOVA was performed on the matching task data. It yielded a significant effect only for picture features, $F(2,133) = 12.434$, $p < .001$. Tukey contrasts revealed that both onset ($M = 4.42$) and motion ($M = 4.56$) conditions performed significantly better than the picture condition ($M = 3.13$, $p < .001$), but that the onset and motion conditions do not differ from each other.

Although these results differ from previous results that did not find differences in the matching data (Mayer, 1997; Moreno & Mayer, 1999), they support the cognitive theory of multimedia learning. According to this theory, in order for successful learning to occur, there must be an integration of the verbally based and the visually based models of the material (Mayer, 1984). This integration may be enhanced by the use of animations over pictures (Moreno & Mayer, 1999). Both the motion and the onset conditions provided the verbal and visual integration needed for matching in the present study. The difference was possibly due to the decreased presentation time that prevented the ceiling effects found in previous research by Moreno and Mayer (1999).

Retention

A 3 (agent properties: no agent, agent, agent with gesture) x 3 (picture features: picture, onset, motion) ANOVA was performed on the retention data. It yielded a significant effect only for Picture features, $F(2,133) = 25.733$, $p < .001$. Tukey contrasts yielded a difference between the picture condition ($M = 1.93$) and both the onset ($M = 4.20$) and motion ($M = 5.07$) conditions. There was no difference between the latter two groups.

Transfer

The transfer task probed the extent to which participants applied the concepts they learned to other problems and exhibited creative solutions. A 3 (agent properties: no agent, agent, agent with gesture) x 3 (picture features: picture, onset, motion) ANOVA was performed on the transfer task data. This analysis yielded a significant effect of picture features only, $F(2,133) = 4.03$, $p < .05$. Tukey contrasts revealed a difference between the onset ($M = 2.13$) and picture ($M = 1.44$) conditions ($p < .05$). The motion condition ($M = 1.89$) was intermediate and did not differ from either of the other two groups.

The differences between the onset and picture conditions provides support for claim that a sudden onset of a color singleton directs attention as needed to assist the construction of mental models that facilitate the implicit inferences necessary to construct creative solutions.

Multiple-Choice Questions

A 3 (agent properties: no agent, agent, agent with gesture) x 3 (picture features: picture, onset, motion) ANOVA was performed on the total score obtained from the multiple-choice questions. This yielded a significant difference only between picture features, $F(2,133) = 7.58$, $p < .001$. Both the onset ($M = 2.13$) and motion ($M = 1.89$) groups significantly outperformed the picture ($M = 1.44$) group ($p < .001$). There was no difference between onset and motion conditions.

Explicit Shallow. The multiple-choice questions attempted to evaluate three types of knowledge (explicit shallow, explicit deep, and implicit deep). A 3 (agent properties: no agent, agent, agent with gesture) x 3 (picture features: picture, onset, motion) ANOVA performed on the data from the questions that tapped explicit shallow knowledge yielded only a significant effect of picture features, $F(2, 133) = 3.08$, $p < .05$. Tukey contrasts showed that participants in the motion condition ($M = 1.64$) outperformed the picture condition ($M = 1.36$), $p < .05$. This result is consistent with findings from the matching task, which tested for shallow knowledge.

Explicit Deep. A 3 (agent properties: no agent, agent, agent with gesture) x 3 (picture features: picture, onset, motion) ANOVA was performed on the data for the explicit deep questions. It yielded only a significant effect for the picture features, $F(2,133) = 7.93$, $p < .001$. Tukey contrasts revealed differences between both the onset condition ($M = .71$) and the motion condition ($M = .79$) when compared to the picture condition ($M = .29$). The participants in the motion condition outperformed those in the picture
condition ($p < .001$). Similarly, those in the onset condition outperformed participants in the picture condition ($p < .01$). These findings suggest that by directing attention appropriately the onset of the color singleton (Yantis & Hillstrom, 1994) facilitated deeper learning of core concepts as effectively as an animation with motion in the present relatively brief presentation. This would seem to indicate that the onset provided the temporal contiguity that, according to Moreno and Mayer (1999), was required to get full integration of the verbal and visual representations.

**Implicit Deep.** The final multiple-choice questions were designed to tap implicit deep knowledge. A $3 \times 3$ ANOVA that was performed on the data yielded no significant effects, but picture features was marginally significant, $F(2,133) = 2.738, p = .068$. Furthermore, the means (picture $M = .96$, onset $M = 1.20$, motion $M = .91$) were in a somewhat similar direction as the transfer data, which attempted to tap the same pool of knowledge.

The means and standard deviations for all conditions and measures are presented in Table 1 below.

**Summary and conclusions**

The study revealed several findings. First, there were no differences due to agent properties and, thus, there was no evidence of split-attention effects. The presence of the agent in the learning environment was not detrimental to learning. It appears that agents can be safely integrated into brief multimedia presentations without fear of interference, as proposed by Johnson et al (2000). Second, most of the analyses revealed differences among the image-type conditions that supported the cognitive theory of multimedia learning (Moreno & Mayer, 1999). Close temporal synchronization of the narration with the animated display enhanced learning, presumably by establishing relationships between the visual and verbal representations. Third, the findings suggest stimulus onset is just as effective and in some cases more effective in directing attention to appropriate parts of the display as motion in a fully animated display.

Putting the ACTION into INTERACTION: What instructors and students DO online

By Johannes C Cronje* (Professor of Instructional Technology)
Faculty of Education, University of Pretoria, 0002 South Africa
jcronje@up.ac.za

Abstract
A common "mistake" made by lecturers teaching online is to do little more than put their notes online, and to support it with some sort of electronic mailing list. Many online learning environments such as WebCT and Blackboard are also designed to support this instructional model. This paper discusses alternative activities that have been used to put the ACTION into INTERACTION in an online teaching and learning environment. Activities discussed include virtual discussions, building virtual desks, and even a virtual student rag procession. The paper also shows which message acts are most likely to be engaged in by instructors, and what message acts are carried out by learners.

Introduction
The word "virtual" that has become associated with what is done over the Internet, always implies comparison "virtual reality" is like reality, "virtual teaching" is like actual teaching. An implied comparison of items is known as a metaphor (Aristotle, s.a.). Much of the World Wide Web takes the form of a metaphorical book with "web pages". Teaching on the web occurs in metaphorical "virtual classrooms". An extended metaphor is a model. The traditional contact lecture is the model for activities in a metaphorical classroom, by way of text-based lecture notes and e-mail and chat room-based questions and answers. Much of this unfortunately lacks creativity. The same boring stuff produced as lectures become boring web pages.

This paper explores the dynamics between the design of internet-based instruction and the response of learners to the activities that they are asked to carry out. Two questions are addressed: (1) To what extent can activity-based learning be conducted over the Internet; and (2) What message acts do lecturers and learners execute over the Internet?

Context
This on-going research has been taking place in a two-year tutored masters' degree in computer-based education at the University of Pretoria. Students range from 23 to 55, and all work full time. Reactions of both the enrolled students and alumni are reported. Teaching is constructivist rather than instructivist. Students meet once a month for three days and keep in contact via the Internet. One module, "Teaching on the Internet" is presented entirely over the Net.

Literature survey

To what extent can activity-based learning be conducted over the Internet?
Russel, (s.a.) shows that the medium of instruction causes no significant difference in student performance. Similarly, Clark (1994) advocates the separation of medium and methodology in research on educational technology, and feels that it is the method, rather than the medium that influences learning. Kozma (1994) on the other hand, argues that certain media attributes demand certain methods. Mabry (1997) describes models for "providing communication resource opportunities similar to those expected from face-to-face interaction".

Conversation
Email bulletin boards and chat rooms are the equivalent of classroom conversation, providing a "'talk' metaphor, which compares on-line interaction to face-to-face conversation" (Baym, 1995). Moreover "An informal, everyday quality is created through the use of smileys, non-standard spelling reflective of vernacular pronunciation, punctuation to indicate pauses rather than speech clauses, special symbols borrowed from programming languages and an extensive special vocabulary" (Marvin, 1995).

Collaborative and co-operative learning
According to Garton (1997) "When a computer network connects people or organizations, it is a social network". Although Anderson and Kanuka (1997) point out that an online forum appears to hold little or no relative advantage compared to face-to-face forums with regard to socialization and ability to communicate, there are other advantages. Employees "would have minimal work time loss and no travel time loss". For Johnson and Johnson (1991) successful co-operative learning has three prerequisites, a mutual goal, individual responsibility and positive interdependence. From the literature then it would seem that the methods of contact teaching could be replicated since medium and method should be separated; but different media may be necessary to simulate different aspects.

What message acts do lecturers and learners do over the Internet?
Learners are likely to adapt their behaviour based on the that they are given because of material behaviour: "The impact of the relationship between material and interpersonal behavior is termed material behavior" (Jones, 1997), because "material acts as a non-verbal message-system with rules that provide some degree of predictability which manages human interaction". Bonnycastle (1997) sees a duality between our signs and ourselves "Depending on a variety of factors, we choose forms of representation that are both individually and culturally determined to facilitate that communication. In turn, that painting, book, idea become part of the environment and the cycle begins again".

Teaching and learning in a metaphorical classroom
The digital classroom in this article used the metaphor of a junior school classroom to teach "Internet-based learning" to adult learners. For Branscomb (1996) "Metaphors serve as a map for sorting out what is similar and what is different when confronting a new problem". I wanted to see how closely I could mimic the events of a real, physical classroom in a web-based environment. Because of this the
visual similarity in my initial digital classroom had to be as strong as possible since the physical differences were enormous. The students never met face-to-face, and neither were they able to communicate face-to-face.

The classroom had two components: A website (representing the "physical" classroom) and an electronic mailing list that represented interpersonal (speaking) interaction that occurs in a classroom. Jones (1997) distinguishes between "a virtual community's cyber-place and the virtual community itself. A virtual community's cyber-place will be termed a virtual settlement". The classroom with its associated mailing list therefore formed the virtual settlement, and had the following characteristics as identified by Jones (1997): "Minimum Level of Interactivity, variety of communicators, a common-public-space where a significant portion of a community's interactive group-cmc occurs; and a minimum level of sustained membership" (Jones, 1997).

The website "classroom" can be viewed at <http://hagar.up.ac.za/rbo/classrm.html>. It had four sections. First there was the blackboard and notice boards. Clicking on these revealed timetables and tasks; the blackboard revealed comprehensive on-line study guides, as suggested by Van Brakel (1996). The chalkboard was a graphic that students could modify, producing graffiti as in a real classroom.

Second was the administrative area with the presenter's desk (linking to my own home page), resource cupboard (with links to subject matter and construction programs such as graphic and HTML editors) and alumni association (with links of a general nature, regarding computer-assisted education).

Third was the poster wall with links to projects by previous students, and links to the "posters" created by current students co-operatively as the course progressed.

Lastly came the learners' desks. Each student had a WWW directory linked to a desk. The student had to replace the generic picture of a desk with a personalized one, and then "fill the desk" with things typically found in a school desk: (1) Your ears (Mail to: ...), (2) Your utility bag (Links to handy utilities such as HTML editors, Search Engines, Clipart libraries, etc.), (3) Your textbooks (Links to useful sites), (4) Your work (Interesting work you have done in other M.Ed. modules), (5) Your hobbies (Links to sites of special interest to you), (6) Your class work (Your answers to all the objectives of the course); and (7) Your portfolio (A link to the portfolio of your examination project).

In this classroom learners did not only find information, but generated their own web pages. The students immediately took on the roles of learners in a schoolroom. They addressed me as "Sir" or "Teacher" in all their emails, tattled on one another, interrupted proceedings with jokes, and generally acted with an air of light heartedness. One student, Mari, went as far as "bunking" class. Instead of sticking to the "desk" metaphor that she had to create, she replaced it with a beach metaphor. She did not have a desk. She had a surf kit instead. Ari, did not show a picture of his desk, but of his two feet resting on it. These results show how the adult learners, when placed inside the metaphor of the schoolroom, exercised typical schoolroom "naughtiness". The other desks show an interesting blend of students' creativity or lack of it—much the same as one would find in a real classroom.

As a special challenge students were allowed to add graffiti to the chalkboard. This was a reasonably complicated task but they found the environment sufficiently motivating, and by the second week of the course, all had written on the board.
We were able to reproduce:

- Posters: i.e. vignettes of information, examples of similar projects, and examples of the work of other students.
- Resource cupboards and toolboxes: i.e. repositories for additional reference information and imaging and website construction tools.
- Presence of other learners in the form of "desks", and
- Conversation by means of a dedicated mailing list.
- What we could not create at that stage was real-time interaction, and that made us miss the clement of urgency thus created.

Humor figured strongly in the class, supporting Baym's (1995) contention that "...humorous performance can be used to create group solidarity, group identity, and individual identity in CMC".

An analysis of the messages indicates that the most frequent actions of the instructor were to (1) make suggestions, (2) give encouragement, (3) explain how to do something; and (4) give directives. The main actions of the learners were to (a) give information, (b) ask questions, (c) present a problem, (d) initiate or contribute to the discussion; and (e) express amusement or joke. The message acts in the classroom were very similar to speech acts in a face-to-face classroom, showing that "Computer-mediated groups can create solidarity through developing interpretive consensus" (Baym, 1995).

A virtual rag procession

Building on the success with humour in the classroom I wanted to extend the virtual community to masters' students in the first and second and course alumni. According to Baym, (1995) "analysis of humor is important because CMC research has been slow to address the formation of group identity and solidarity, though such phenomena occur in on-line groups and are negotiated, in part, through humor". The model I was the University rag, a carnival, culminating in parade through Pretoria. Although graduate students never take part, my rag was exclusive to my graduate students and alumni. The url is <http://hagar.up.ac.za/catts/jool/jool.html>. Unlike my students' other work this was not for marks, but the model was a competition. The first prize was Microsoft Front Page sponsored by Microsoft South Africa. It was not aimed at building new skills but at community building. Kozar (1995) says that "Not only does this kind of communication allow people to renew and strengthen friendships, but it also provides them with an interface for play, and through play for the creation of new patterns for the performance of tradition".

When the students recognised the metaphor, they were able to expand it. They found corporate sponsors whose pages were linked to the 'floats' and credit was given as would have been done on a physical float. Students asserted their right to express their own opinions. Although the theme 'Coin the barrel' was intended as an anti-gun-ownership campaign, Dolf, sponsored by the Magnum gun-collectors magazine, constructed a float giving "Good reasons why you should spend coins on barrels". This supports Baym's (1995) contention that "Humor also serves as a means of creating individuality when the cues we use to define ourselves in face-to-face groups are unavailable".

Mignon, took revenge on the sexist idea of having a "Rag Queen" beauty pageant, and constructed her own "Rag Man" float. She invited her fellow students to enter her competition and put their pictures on her site as additional floats. In this way she demonstrated that "humor is a joint production, which the audience not only understands but helps create. This joint authorship enhances group identity and
solidarity" (Baym, 1995). She put my picture at the top of the float – an act reminiscent of the manipulation of teachers' pictures so prevalent in schools. The school metaphor created in the initial classroom, therefore, had survived even beyond the duration of the module.

Mari crept into the hearts of the virtual community with a very touching float, depicting the first sonar scan of her unborn baby, together with a poem explaining why, for the sake of the unborn child, we should 'Coin the barrel'. She demonstrated that "it is in part through humorous performance that particular posters overcome the seeming anonymity of the computer medium to develop their own voices" (Baym, 1995).

**Conclusion**

This section will briefly state the conclusions reached and lessons learnt in answer to the two original questions.

**To what extent can activity-based learning be conducted over the Internet?**

The physical attributes of an actual classroom, i.e. chalkboard, resource cupboard, teacher's workstation, learners' workstations, posters and portfolios can easily be metaphorically recreated in cyberspace. Learners' reactions to these creations are similar to those of learners in a physical environment. Group cohesion can be created through humorous interchange, large amounts of information can be sent across by e-mail based "virtual lectures". Student and teacher activities in metaphorical classrooms correspond closely with their activities in face-to-face classrooms.

**What message acts do lecturers and learners do over the Internet?**

Learner response to the metaphor was to "down age" and engage in the role-play of being in a school classroom. This spontaneous role-play activity assisted greatly developing a team spirit in the class, but while they engaged in the role-play exercises, nevertheless remained adult in their decision-making.

Critical Evaluation Skills for Web-Based Information: 
"Lies, Damned Lies" and Web-Based Information

Marie K. Iding, Martha E. Crosby Brent Auernheimer and E. Barbara Klemm
University of Hawaii at Manoa

Critical evaluation skills are central to education as reliance on Web-based information increases. This is particularly true now that the editorial and peer review processes are implicitly removed from experts and textbook authors and placed into the hands of students searching the Web for material related to research projects. Since it is increasingly difficult for Web sites to attract readers' attention, the Web site designers increasingly resort to exaggerations, encouraged by the anonymity afforded by this technology. In the sciences, for example, students must sift through false or exaggerated claims, non-refereed research, and various forms of misinformation. These critical evaluation skills are no less important in other fields where students cite non-refereed research or quote papers posted on the Web. In response to this need, a number of authors have posted criteria for evaluating Web sites, although little research has been done regarding this process. Furthermore, teachers frequently assume it was the responsibility of other teachers (e.g., the English teacher) to have covered this topic (Iding, Landsman, & Nguyen, 2001). The strong need for both research and the development of effective instructional interventions in this area provides the impetus for this paper, which examines aspects of Web-site evaluation among high school biology students, university-level pre-service teachers and computer science students. We represent the perspectives of faculty working in different disciplines. By addressing these topics in an interdisciplinary forum, we hope to engage educators and researchers from other disciplines in constructive dialogue in which we co-develop instructional goals and research agendas to increase the critical evaluation skills of ourselves and the teachers and students with whom we work.

The emergence of powerful Web searching tools enables K-12 teachers and their students to locate a plethora of potential resources for teaching and learning, but the operative term is "potential", especially when considering possibilities for these resources in teaching and learning environments. As an initial step in addressing these needs, we first discuss research relevant to teaching critical evaluation skills, first by examining the credibility ratings of information sources by pre-service teachers, and secondly, by describing an instructional intervention carried out with high school biology students who were taught to evaluate Web-sites. For example, Klemm, Iding & Speitel (2001) compared pre-service teachers' and scientists' evaluations of the credibility of 31 information sources for science information. They found some noteworthy discrepancies. For example, elementary pre-service teachers rated material from weekly investigative television newsmagazines like 20/20 as among the highest in credibility, while scientists rated them among the lowest. In general, pre-service teachers tended to rate information sources as being more credible than did scientists. These discrepancies clearly demonstrate the need for critical evaluation skills among the general public and educators in particular. In another study, Iding, Landsman, & Nguyen (2001) carried out an instructional intervention with high school biology students, rather than teachers. Students received instruction in critical Web-site evaluation and developed their own criteria for evaluating science Web-sites generally and the science information contained in them, more specifically. Results indicated that students' lists of criteria were more extensive after instruction. They reported that they would devote more time to evaluating Web-material in the future and that their confidence in their ability to evaluate Web-based scientific information had increased.

Next, we will mention instructional and research-related issues that emerge from these studies and other work (Lynn, Bell, & Hsi, 1998). For example, what factors should be provided in order to facilitate the development of critical evaluation skills? Suggestions include providing an orientation to some basic categories for their evaluation (e.g., validity, credibility), or providing computer-based scaffolding or tutorials, working collaboratively to discuss and/or create actual criteria for evaluating Web sites, and finally, gaining sufficient skills evaluating real Web sites, both individually and collaboratively. Other basic research questions include the need to elucidate the professional needs of teachers and the adequacy of tools for preparing and supporting teachers in selecting and teaching about selecting valid, credible, and useful Web-based resources. Secondly, in addition to addressing the needs of the teachers and students, research needs to address design and credibility aspects of Web-sites and how these factors affect teachers' and students' judgments about information and information sources. For example, questions driving this
research could include the following: Do design aspects outweigh actual information content in influencing credibility judgments? What aspects of Web-based information affect users' judgments? How confident are students and teachers about their ability to make judgments about information in different content areas? In the next section, we describe some of the issues around Web-based information and Web-site evaluation that are pervasive among university-level computer science students.

Computer Science faculty find their students struggling with information on the Web. Students in courses spanning lower-division general education critical thinking to graduate research technique are frustrated and mislead. Students in critical thinking courses can be overwhelmed with the abstract notions of logic and argument, as well as the detailed activities of gleaning Web material and thinking logically about it. We believe that teaching critical thinking in the context of introductory computer science courses complements “information competence” training provided by many university libraries. For example, The California State University Information Literacy Fact Sheet describes several ways to incorporate information competency into university curriculums: freshman orientation courses, general education courses, cornerstone classes in major areas, and competency-based mastery. We also observe that graduate students are unable to determine the trustworthiness of materials found on the Web. We speculate that although the students have an abstract understanding of peer review and the scientific publication cycle, the students miss cues to correctly determine the trustworthiness of researchers’ Web pages, technical reports, industry publications, and peer-reviewed on-line conference proceedings, magazines, and journals.

We also believe that recent research on Web usage provides insights into teaching information competence. For example, Morrison, Pirolli, and Card (2001) surveyed thousands of Web users about why they use the Web (purpose), how they use the Web (method) and what they are looking for (content). Purpose was broken down into “finding information” (25 percent), “compare/choose” (51 percent), “understand” (24 percent). Users’ methods were “explore” (two percent), “monitor” (two percent), goal directed “find” (25 percent), and goal directed “collect” (71 percent). Note that 96 percent of user activities were goal-directed. Nielsen (2001) summarizes this research: “Users’ most important Web tasks involve collecting and comparing multiple pieces of information, usually so they can make a choice.” That is, Web users generally do tasks similar to what students are asked to do in the classroom. We speculate that this general usability research may provide insights into teaching skills for critical Web use. Future directions for research include collecting more data of how students use material obtained from the Web and analyzing the information derived from studies both qualitatively and quantitatively. However, many questions still remain on how and what to measure in order to collect meaningful information. Students must be trained to evaluate Web-based information critically and we want to develop software tools or metrics that can facilitate this training. We also must have a better understanding of how humans decide if information is valid. In order for this to happen, however, we need to discover what dimensions form a basis for value judgments of veracity. We expect that results from this research will be able to provide some insights into students' beliefs and attitudes about the veracity of information found on the Web. In addition, we hope this research can address how those beliefs and attitudes are related to task performance.

1Lies, damned lies and Web-based information is a play on the famous quote “lies, damned lies and statistics” that is typically attributed to Benjamin Disraeli. (See the autobiography of Mark Twain by Samuel Clemens)

Getting Stuck in the World Wide Web: The Impact of Design on Navigation

Jason Daniels, Department of Psychology, University of Alberta, Canada, jDaniels@ualberta.ca
Bonnie Sadler Takach, Department of Art and Design, University of Alberta, Canada, bbs@ualberta.ca
Connie Varnhagen, Department of Psychology, University of Alberta, Canada, varn@ualberta.ca

Abstract: Getting lost is a common phenomenon for anyone who has ever navigated through a confusing Web site. What makes a Web site confusing? Why do people get stuck in the World Wide Web? In this study we looked at how people reacted when presented with Web sites that differed in level of familiarity. We found that when people viewed Web sites with an unfamiliar structure, they became confused and they tended to take more time when navigating. Future research will examine what factors are involved in successfully extricating oneself from the World Wide Web.

Introduction

One highly documented phenomenon, which exemplifies a potential pitfall of allowing users to control their own navigation, is getting stuck or lost in hyperspace (Boechler 2001). No one really knows for sure why people seem so prone to this problem. One possible reason that people get lost is that they rely on some preformed concept of how to find their way through hyperspace. For example, many users seem to navigate from top to bottom, left to right, page to page (Eveland & Dunwoody 1998; Niederhauser, Reynolds, Salmen, & Skolmoski 2000). Another possibility is that the cues as to relevance and temporal precedence are not the same for a Web page as they are for books or other print-based media (Sundar, Narayan, Obregon, & Uppal 1999; Tewksbury & Althaus 2000). It is left up to the user to select which information is important to attend to without the benefit of familiar cues. A user who is not familiar with the structure of a particular Web site may not recognize the significance or relevance of the cues, and may instead look for cues that they have seen and used before.

We are initiating a program of research to begin to determine how it is that people navigate through hyperspace and why this process breaks down so frequently. The first study, which is reported here, examines what impact level of familiarity has on navigation. We compared two Web sites with different levels of familiarity classified as text-based and metaphor-based respectively. The metaphor-based Web site was designed to represent links metaphorically with pictures. The text-based site represented links with text.

We hypothesized that participants would spend different amounts of time navigating through the Web site based on their familiarity with the structure of the Web site that they viewed because the cues that they expected would not be there. We believed that people would spend more time navigating the unfamiliar site. We also believed that there would be differences in the amount of information recalled based on the type of Web site that they were viewing, because getting stuck and being confused by the Web site might actually compel users to internalize the structure of the unfamiliar Web site and thus lead to an increase in the amount of information recalled.

Method
Participants and Materials

Participants were 93 undergraduate psychology students from the University of Alberta. They received course credit for their participation. The majority of participants (85%) were 18 to 20 years of age, 6% were younger than 18, and 9% were older than 20. Of the 93 participants, 62% were female and
38% were male. The majority of participants, 66%, were in their first year of study, 22% of participants were in their second year of study and the other 12% where either in their third or fourth year of study. There were 45 participants in the metaphor-based condition and 48 in the text-based condition. The materials were two Web sites, an online questionnaire, and a free recall task.

**Procedure**

Participants were randomly assigned to view either one type of Web site or the other and were asked to evaluate the Web site. They were given a questionnaire to fill out after they were finished looking at the Web site. The participants were then asked to complete a free recall task, about which they had no prior knowledge. There was no time limit given for any of the tasks, and the participants were not told of the hypotheses of the study.

**Results and Discussion**

Participants viewing the metaphor-based site rated the Web site significantly more confusing and less understandable than participants viewing the text-based site. Participants also spent more time on the less familiar site. The lack of a familiar structure seemed to be a hindrance for the participants in the metaphor-based condition. Although participants in the text-based condition often reported that the site they were viewing was boring, and rated their site as less interesting than participants in the text-based condition, they were able to navigate more quickly through the site than participants in the metaphor-based condition. This suggests that even though the familiar structure may not have been as visually appealing as the less familiar one, the cues were transparent and participants did not have to discover the meaning of the cues.

While lack of a familiar structure did seem to be a problem for navigation, it did not impact participants' abilities to recall information implying, perhaps, that participants did not internalize the structure of the Web site. There was no difference in the amount of information participants were able to recall, either about the structure of the Web sites or the specific content that was located on the Web sites.

People come to Web sites with preconceived notions as to what Web sites should look like and the conventions that should be used. When these preconceived notions are not upheld, it can lead to an increased level of confusion and frustration when navigating online. When we are driving, or otherwise navigating through a physical environment, we rely on conventional cues such as street signs or traffic signals to aid us in arriving at our desired destination. Similarly, when navigating through Web sites, we have expectations about how navigational cues should be implemented. In unfamiliar environments, people have a hard time recognizing the significance of navigational cues. We plan to extend our research to examine what factors are the most important for successful navigation and to gather further evidence as to why people get stuck in the World Wide Web.

A Project-Based Approach: Training Teachers in Classroom Computer Applications

Terry H. Daniels, Ed.D.
Department of Education
St. John's University
United States
crtstringer@oobox.com

Abstract: In order to teach K-12 inservice and preservice teachers to use computers and instructional technology to augment their instruction, Internet use was integrated into a face-to-face master's level education class at St. John's University. After setting course outcomes, a curriculum was developed working backward to create an ordered series of instructional tasks to achieve those outcomes. The procedures didn't require sophisticated software and can be replicated in the classroom using a word processor.

Introduction

Are today's teachers ready to integrate technology into their classrooms? According to the International Society for Technology in Education, ISTE (2000) a major problem in achieving this goal is the lack of teacher expertise. According to Jayroe, Ball and Novinski (2001) the difficulty faced by many educators is how to introduce technology into the curriculum in a meaningful and constructive manner. Inservice teachers need to be able to understand the usefulness of how technology can be effectively used in the classroom (Franklin, Turner, Kariuki & Duran, 2001).

Discussion

Many new teachers leave undergraduate schools with limited knowledge of how to use technology in the classroom, and in some cases the university faculty are "neither modeling the use of technology, nor requiring students to use technology" (O'Bannon, Matthew & Thomas, 1998). Before teachers enter a classroom they must be technologically literate. Professors must be proficient in the use of technology, and integrate technology into their existing courses (Kahn, 1997). There are schools of higher education that presently do not adequately integrate technology into their teaching (Rosenthal, 1999). Inservice teachers use the methodology that they feel comfortable with, when presenting a lesson. When a prospective teacher is taught with technology, this becomes embedded in their schema, and makes it easier to use when they teach (Plotnick, 1995). Technology is not central to teacher preparation experience, and most technology instruction is teaching about technology, not teaching with technology across the curriculum (Beck & Wynn, 1998). Albion and Gibson (2000) observed that if teachers are to become successful at adapting technology into their curriculum, they require an understanding beyond that of being confident in using computers in their daily lives.

Implementation

It was important to engage learners in meaningful hands on projects from the onset of classes. Through the use of project-based building block constructivist methodology a course was designed that gave learners new ideas on ways to infuse technology into their curriculum while learning about instructional technology. The course of study was divided into projects. Each project required mastery before attempting the ensuing project. Projects included; e-mailing a graphic attachment in a word processing document, locating and evaluating five curriculum-based Web sites, creating classroom/teacher
material using Microsoft Word, presenting subject matter using PowerPoint and creating a Project-Based thematic unit using Inquiry-Based Learning. A rubric was given to each student delineating what was required for each project. Grades were posted to the class Blackboard Web site. This required the learners to monitor Blackboard where relevant announcements and projects were posted.

Conclusions

It is important in any course of study where instructional technology is used to have students become engaged in meaningful hands on projects. Summers, Lohr and O’Neil (2002) discuss the importance of a learner being able to transfer what they have learned in the classroom to real life situations. Through connecting technology with active involvement in learning Kommers and Mizzoguchi (2000) believe that teachers create a knowledge base that is described as a key issue by constructivists. Lloyd, Merkley and Dennenbring (2001) contend that learners must feel comfortable and understand the relevance of using various technologies upon graduation in order for it to become part of the educational process. Technology has an important role in teaching. Technology should not be taught in isolation but used to augment traditional teaching methodologies by providing alternative means of obtaining information.

Accessibility and Transparency in Tamid's Civics Teachers On-Line Community

Myriam Darmoni Sharvit
TAMID - On Line In-Service Teachers Training Center
The Open University of Israel
Israel
myriamd@oumail.openu.ac.il

Abstract: This paper is a report of the early findings of a study conducted within Tamid's Civics Teachers On-Line Community, operating at the Open University of Israel. At "Tamid", we aim to improve the standards of civics teaching in High schools by developing a specific environment that enhances democratic values among in-service teachers for the benefits of their students. Democracy is dynamic and evolves and improves according to social, cultural and technological changes. Accessibility and transparency are two qualities of the World Wide Web that may deeply influence tomorrow's democracy. At Tamid, the interactions between the teachers are examined from the pedagogical content knowledge building perspective. Early findings show that On-Line relevant resources and assignments encouraged some teachers to relate to their peers' work, to share their own resources and to use them with their students; others witnessed they used resources and enjoyed discussions in a passive mode.

Introduction

Israel's internal cleavages are deepening and the teaching of civics became a very important challenge for Israel's education system. A new civics curriculum that is for the first time aimed at the Secular, Religious and Arab young Israeli citizens was introduced in 2000. This new curriculum sees democracy as a way of life rooted in values and principles and not only as formal set of institutions and processes. This was our opportunity to meet the teachers' needs and provide them a specific on-line educational environment in order for them to cope with these heavy conceptual changes. The debate on the democratization influence of the web convinced us to examine civics teachers on-line learning patterns. Accessibility and transparency are tools that enable the implementation of democratic values, it was interesting to check if a widely open and accessible on-line environment could enhance a meaningful and practically democratic process of learning: pluralistic debate, freedom of expression, respectful interactions etc....

Our project started with 20 Civics teachers in spring 2000 as a new branch of the Tamid environment for Science Teachers. Since October 2001, we train 120 teachers in 5 geographical groups by way of an on-line course. Apart from the on-line course, the teachers enjoy valuable resources both at the knowledge and pedagogical levels. Tamid's site is wide open to all with no need for password as part of our genuine desire to provide a design, accessible and transparent, to all Civics Teachers. We were interested to check if the on-line wide-open Tamid environment was motivating teachers to share their resources/knowledge with their peers and engage reflective dialogue around specific and general teaching problems/dilemmas. Was there a correlation between the fact that our environment was accessible and transparent to all civics teachers and the quality of the interactions between teachers and moderators and among peers teachers?

The Study: Building together practical disciplinary knowledge

"There may be some new form of community developing among the myriad solitaries perched in front of their screens and connected only by their fingertips to the new web defined by the internet. But the politics of that "community" has to be invented." Benjamin Barber, 1997.
Inventing the "politics" of our civics teachers' community was not an easy job since we had to create a climate of mutual trust as a condition for a meaningful learning process. Coordinating the aspirations of each one of different participants, thinking over what is a meaningful feedback, discussing the advantages and the risks of a transparent environment in which everyone's assignment is subject to the group's criticism or praise, dealing with others' opinions and experience the suffering that may imply tolerance. These are only a tiny part of the ongoing questioning which the developing team and the teachers are experiencing day after day at Tamid.

Our research is based on one On-Line course that has been running in five geographical groups from October 2001 to April 2002. 120 in-service teachers attended the course. Electronic discourse was taking place in both a "national" discussion group - where actuality issues where discussed from the point of view of practitioners that needed to use up to date material for explaining curricular concepts - and local groups - where assignments were mainly oriented toward analysis of students' texts and knowledge building trough academic articles and their "translation" into didactical practice.

As part of the learning process the teachers had to develop their own sense of responsibility and autonomy since there was no external due-date for the diverse assignments. Still, all of the assignments implied interaction and discussion. Each teacher had to lead the discussion one academic article within an on-line discussion group. This dialogue was a very fascinating alchemy since it was an occasion to enhance the connection between the subject matter and its didactics besides inducing reflective thinking among the teachers. Who started the discussion? Who reacted? How many "reactions" to a topic? What made a topic turning into a highly reflective learning process? To which extent did "passive" teachers witnessed the use they made of materials or arguments that came up during the discussion? Which patterns of participation: pedagogical issues or ideological views, passive versus active behaviors, consumer or contributor etc..

Early Findings

The building of an on-line teachers community is a process. But our early findings (evaluations, questionnaires, interviews and discussion groups analysis) show that for most of the teachers, Tamid site became a professional meeting place: to submit a test to peers and moderators appreciation, to view links to up-to-date articles on relevant issues, to ask specific questions that came up at school, to take part on discussions on political discussions and to think together with peers of new strategies to teach highly controversial topics, to inform peers of the use that was made with students of material or arguments. These occur in a highly respectful climate, accessibility to all but still no curses and no anonymous participants. Thanks to Tamid's web environment, teachers from the periphery could enjoy the same high quality resources, experts and facilitators as teachers from the center of the country but this is still a theoretical access since most of these teachers usually lack the technological tools to make their participation in the on-line learning process meaningful.

Teachers are practitioners that need to update, confront and articulate their subject matter knowledge and their teaching skills. Therefore, building practical knowledge (from home) through an easily accessible site designed to meet their needs is highly motivating for in-service training teachers.

Assessing Information and Communication Technology Literacy of Education Undergraduates: Instrument Development

JoAnne E. Davies <joanne.davies@ualberta.ca>
Michael Szabo <mike.szabo@ualberta.ca>
Craig Montgomerie <craig.Montgomerie@ualberta.ca>
Department of Educational Psychology
University of Alberta
Edmonton, Alberta, Canada

Abstract: In recent years, the view that Information and Communication Technology (ICT) is vital in K-12 education has become widespread. ICT use in schools has increased and various professional bodies have set ICT standards for students and teachers. Schools of education are under pressure to produce teachers who are able to effectively integrate technology into their teaching. However, most teacher preparation programs do not adequately prepare teachers in ICT, nor assess candidates relative to ICT standards. This paper discusses the development of a computerized system to assess ICT declarative and procedural knowledge and to provide a profile to the participant.

Introduction

In recent years, governments, education organizations, and researchers have increasingly supported the view that incorporating ICT into learning and teaching is an important aspect of keeping the curriculum relevant and preparing students for their future in a complex knowledge-based world (Alberta Education, 1999b; CEO Forum on Education and Technology, 1997; Jonassen, 1995; Logan, 1995; Milken Exchange on Educational Technology, 1999; Thornburg, 1991). Data that provide insight into the computer literacy level of incoming undergraduate education students would be helpful to faculty designing appropriate curriculum. However, there is currently no assessment tool that establishes the ICT literacy level of current or prospective students. The predictive validity of a high school transcript or grade 12 English or mathematics marks is insufficient. How do the ICT skills of recent undergraduate students compare with the skills indicated at the Grade 12 level of the Provincial technology outcomes? Although the Best Practices in Technology documents (Alberta Education, 1999a) indicate that much ICT-related activity is occurring in schools, and an optional ICT K-12 curriculum has been available since June 1998, there are currently a few students entering educational technology courses at this university who have literally never turned on a computer (based on an informal "hands-up" survey of students in September 1999), while some students are familiar with some aspects of ICT, and a few are quite adept. This paper, part of a larger study (Davies, 2002) discusses the development of several Web-based instruments (Research Consent Form, Attitude Survey, Background Survey, Knowledge and Performance Tests) which assess the computer literacy level of incoming undergraduate education students.

Development of the Instruments

The Background Survey and Knowledge Test were implemented using ASPs written in the VBScript (Microsoft Corporation, 2000b) programming language. The ASP dynamically generated a Web page containing an HTML form with question and response data stored in a Microsoft Access 2000 relational database on a Windows server. The Background Survey included a variety of form field types that enabled implementation of different question types: radio button (multiple-choice/single response), drop-down list (multiple-choice/single response
with a large set of possible answers), check box (multiple-choice/multiple response), and text box (short answer). The Knowledge Test was composed entirely of multiple-choice questions with five possible radio button answers.

The ASP also inserted client-side JavaScript (Netscape Communications Corporation, 2000) code into these HTML pages for the purpose of quick data validation. When the participant clicked on the form “Submit” button, the JavaScript local editing procedure was invoked. If unacceptable data were found, an error message window was displayed on the screen and the form was not submitted. For example, the Background Survey asked for the year of high school graduation. Acceptable responses had to be a four-digit year not greater than the current year. Upon acknowledgment of the error message, the participants’ display was automatically scrolled to the question where the error was found. The JavaScript procedure also checked to see whether all applicable questions had been answered. If missing responses were found, a warning message window was displayed on the screen. Since it was unethical to demand that the participant answer all questions, the participant was then given the choice to return to the first missing response or to submit the data. The Knowledge Test responses were immediately scored by comparing with the correct response stored in the database for each item.

Observations of participants filling in the Web-based forms indicated that the JavaScript validation routines contributed to the completeness and accuracy of the data collected. For example, one participant was observed to receive the warning message stating that not all questions were answered. The individual read the warning message, returned to the form, stated “Oops, I missed that question,” clicked on a response, and proceeded to submit the form with all questions completed. In all of the Background Survey data collected during the pre-course pilot test (34 participants x 35 questions each for a total of 1190 items) only 1 missing response and no invalid responses occurred. It would have been extremely time-consuming to ensure this level of data completeness and accuracy with paper-based forms. In the corresponding Knowledge Test data (952 items), there were 45 unanswered items. These were treated as incorrect responses when computing the overall test score. The vast majority of the missing responses (39) occurred because two participants attempted the first few questions and then submitted the form without checking responses for the remaining questions. Some additional messages were added to the Knowledge Test to ensure that students would be aware that there was no penalty for guessing.

The Performance Test was a much more technically complex instrument than the Knowledge Test since it required automating the analysis of files that participants manipulated on their local computers. The actual applications tested were established based upon required ICT skills, but were delimited by criteria such as time constraints for the initial instrument development, minimizing problems in collecting data, and allowing students to take the Performance Test with varying versions of application software on either the Windows or Macintosh platform. The solution chosen was to create a Visual Basic for Applications (VBA) (Microsoft Corporation, 2000) procedure within the same Access database described earlier. Web-based (especially client-side) programming techniques were avoided because of variable client computer setup and security issues involved in attempting to examine files on a client computer over the Internet. This part of the system required exchanging a set of files (compressed into a single archive) between each participant’s computer and the database server.

During the Performance Test, the VBA procedure was continually running, monitoring a certain file directory every 60 seconds for arriving submissions and executing an automated scoring routine. The VBA scoring procedure implemented programming techniques (e.g., use of Microsoft Automation objects, methods and properties) which enabled automated execution of file system commands (e.g., file searches and directory listings), reading of text stream files, interfacing with external applications (e.g., Microsoft Word and Excel), opening files in these programs, and examining their object hierarchy.

The automated scoring routines were subjected to several iterations of testing and refining. The first author created about a dozen test cases - sets of computer files representing completed student practical tests - with a mixture of completely correct, partially correct and completely incorrect solutions for each task, completed using different software versions on different computer platforms. These were subjected to the automated routines and the scores for each item of each test case were manually checked for accuracy. This was repeated until all of the
test cases were being properly scored. These same processes were repeated with files created by various expert
reviewers as well as the entire group of student files resulting from the performance pilot test. Programming
efficiency was also examined and improved until the time required to score the performance test averaged less
than a second per test case.

The procedure that scored the spreadsheet activity of the Performance Test highlights the flexibility in the
software used by participants allowed by the programming solution chosen. Spreadsheet files created in Excel 5
and 98 for Macintosh and Excel 95, 97, and 2000 for Windows formats were all scored without technical
problems. In addition, the procedure also worked for files created in other programs such as Apple/ClarisWorks
or Corel Quattro Pro then saved in Excel format. Multi-format flexibility assumes that the spreadsheet activities
chosen for the test are limited to common features available in the different spreadsheet file formats. Only
common tasks such as basic text or number formatting, cell alignment, and formulas were used. This was
adequate for the level of expertise being measured in the target population.

Pilot Test

The instruments were pilot-tested on a thirty-five volunteer undergraduate education students prior to the main
data-gathering period. These students were drawn from registrants in two Summer 2000 sections of the
recommended educational computing option course. The students completed the Web-based forms and the
Performance Test in a campus lab on Pentium 450 MHz computers with Microsoft Windows 98 and Office 2000
(Microsoft Corporation, 2000a) installed. No student chose the options of using a Macintosh computer, or to fill
in paper-based copies of the online forms. The same group of students was later invited to participate in a
Knowledge and Performance post-test, which was held on the second-last day of the term. After completing the
test, the students were given a list of answers to the multiple-choice Knowledge Test, computer files providing
correct solutions to the Performance Test, and personal help with any questions they had.

Instrument Validity

Content validity of the instruments was independently judged by three individuals who have expertise in
educational technology: a faculty member, a PhD student, and a senior undergraduate student who had worked
for a year as a marker in the educational technology undergraduate course. A number of modifications were
made to the instruments based on the feedback from these initial reviewers. For example, some items that were
deemed inappropriate were deleted from the instruments, the wording of some items was clarified, computer
displays were improved, and new items suggested by the reviewers were added. These reviewers also served to
verify that the system was operating without technical errors. Additional educational technology experts were
called upon to similarly review the instruments after the pre-course pilot test. Improvements to the instruments
were made as a result of this second round of validation activities.

Feedback on the instruments was obtained from the pilot-test students in a number of ways. First, during the
pre-test, the researcher asked the students to raise their hand if at any time during the testing they found any
information on the consent form or any question on the instruments to be unclear or inappropriate. A few such
questions occurred and were discussed privately with the participant. These inquiries were noted on the
researcher’s printed copies of the instruments. Second, after reviewing the pre-test data, several students were
contacted by email and asked for more information concerning their answers to certain items on the Background
Survey. This resulted in some ideas for additional changes to the survey. Third, during the post-test, the
students were asked to fill in a short feedback sheet. They were asked whether there were items that they felt
were unclear or inappropriate on either the Knowledge or Performance Test, and whether they had any
suggestions for additional items that could be included. All of these sources of student feedback were reviewed
and resulted in modifications to the instruments.
Statistical correlations were computed as indicators of test validity (see Table 1). A high correlation \((r(33) = .460, p<.01)\) between the Knowledge pre-test and Performance pre-test scores provided evidence of concurrent criterion-related validity. That is, there was logically some commonality in the underlying constructs that these two tests measured. Strong correlations between the course midterm exam which occurred two weeks after pre-test and the pre-test Knowledge \((r(30) = .533, p<.01)\) and Performance \((r(30) = .606, p<.001)\) scores were evidence of predictive criterion-related validity.

Correlations between the course final exam and the post-tests (run 1 day before the exam) were: Knowledge post-test \((r(21) = .409, p =.059)\) and Performance post-test \((r(23) = .673, p<.001)\). The latter correlation was significant and offers strong evidence of concurrent criterion-related validity. The first correlation, while not quite statistically significant at the .05 level \((p=.059)\), still offered some evidence of validity. It should be noted that the course exams during the Summer 2000 term were entirely performance-based, thus it was not surprising that the correlations between the course exams were stronger with the Performance Test than with the Knowledge Test. Also, it was easier to obtain some marks by sheer guessing on a multiple-choice test than it was on a performance-based test. Correlations between the course final exam and the pre-tests were: Knowledge Test \((r(28) = .522, p<.01)\) and Performance Test \((r (28)= .688, p<.001)\). All of these correlations were further evidence of predictive criterion-related validity.

Table 1: Pilot Test Instrument Validity - Correlation Statistics

Instrument Reliability

The Background Survey was not constructed as a scale where all items contributed to an overall score. Rather than computing internal consistency statistics, reliability of this instrument was established by selective re-testing. Four of the students who had volunteered to participate in the initial instrument evaluation were re-tested using a different format for presenting the questions (as an interview rather than online written questions). No differences in the responses from the two forms were found, indicating high reliability (Fraenkel & Wallen, 1996) although these participants did offer a few suggestions for clarifying the wording of a few items. The consistency of responses was not surprising, since most of the questions on the survey would be considered objective (mainly factual information such as whether or not they own a home computer). Answers to questions like these are likely to be answered the same in a test-retest situation where there is little time between tests.

Cronbach's alpha coefficient was computed for the pre-test Attitude Survey (.63), the Knowledge Test (.79), and the Performance Test (.91). The Attitude Survey reliability was judged too low for meaningful data interpretation (a widely accepted lower limit for alpha is .7), the second was acceptable, and the latter was exceptionally high, being at the level of marketed achievement tests (Fraenkel & Wallen, 1996, p.163).

1 In this notation, \(r(33)\) means \(r(df)\), where \(df\) is the degrees of freedom (equal to \(n-1\))
Improvements to the Attitude Survey were essential to establish solid reliability. Analysis of the inter-item correlation matrix identified three items that were poorly associated with the other items and thus did not contribute well to the overall test score; these items were modified. In addition, since the survey originally consisted of only 12 items, reliability could be easily raised by increasing the number of related items (Fraenkel & Wallen, 1996, p.163). A target of 20 items was established.

The alpha coefficients for the post-test Knowledge Test and Performance Test (run again at the end of term as a post-test) were not as high, .63 and .84 respectively. This was because the tests included some questions deemed by experts to be easy (equivalent to the stated prerequisites for the recommended educational computing course), yet which stumped many students in the pre-test, effectively screening individuals with very low knowledge or practical skills. Tests are not always equally effective in different situations (Murphy & Davidshofer, 1991); these tests were less effective as a post-test after completing a course which covers much of the content of the tests and provides remediation for missing prerequisite skills.

In the pre-course Knowledge Test, no questions (out of 28) were answered correctly by all students. In fact, the easiest question was answered correctly by 88% of students. By contrast, in the post Knowledge Test, there were 4 questions answered correctly by all students, and another 8 questions answered correctly by at least 75% of students. There was less overall variance in the post-test scores than in the pre-test scores. Also, items of zero variance (same score for all students) cannot be correlated with other test items and thus do not enter into the reliability calculations, which reduces the reliability coefficient (a measure of average inter-item correlation).

The course appears to have been effective in raising the student scores. The mean pre-to-post gain on the Knowledge Test was 17.52. A one-sample t-test on the gain scores (post – pre), comparing them to a test value of zero (equivalent to a dependent or paired samples t-test using the pre and post scores) found the difference statistically significant. On the Performance pre-test, no questions (out of 24) were answered correctly by all students, while on the post-test, 6 questions were answered correctly by all students. The mean pre-to-post gain on the Performance Test was 26.07; the one-sample t-test on the gain scores compared to zero found the difference statistically significant. It should, however, be noted that the difference in cases between the pre and post-tests must be considered; the students who didn’t participate in both tests were not part of the gain analysis and may have differed from those that did.

The pre-to-post gains on these two tests affirmed the effectiveness of the instruction and were additional pieces of evidence for the validity of the tests. It demonstrated that participants who have had more training or practice with ICT tools (i.e., the students at post-test time) scored much higher than those with less (i.e., the students at pre-test time). This is logically consistent with what the tests purport to measure.

Time Required to Administer Instruments

The pilot pre-test also served to verify that the instruments could be completed within a reasonable timeframe on a single day. The actual time required for students to complete all of the forms and tests was approximately 1.5 hours, about 0.5 hour for all of the online forms (consent, attitudes, and knowledge) and 1 hour for the performance tasks. The start and end time for each participant’s work on each online form was stored in the database, making it simple to calculate the average time required to complete a form. In the case of the Background Survey, the average time was about 8 minutes, and the maximum time was 12 minutes. The maximum time required for the 12 Attitude items was around 4 minutes. For the Knowledge Test, the minimum time required was 3 minutes, the maximum 25 minutes, and the average 13 minutes. For the Practical test the minimum time required was 12 minutes, the maximum 65 minutes, and the average 36 minutes.

Observations from the Pilot Test

A number of statistics were computed to provide a general picture of the pilot data. Histograms of the pre and post Knowledge and Performance test scores revealed that these distributions were approximately normal, with
the post-tests having much higher means and lower variances than the corresponding pre-test. Overall, the achievement on the pre-course tests was quite low with the means of both tests being below 50%. Comparing the test questions against the recommended educational computing course curriculum and stated prerequisites, the researchers concluded that marginally acceptable course prerequisite skills and knowledge (basic computer operation, file management and word processing) would be indicated by a score of at least 50% on the pre-tests. On the Knowledge Test, 44% of students did not meet this standard and 59% did not meet it on the Performance Test, indicating that many students do not possess adequate course prerequisites. A more comfortable level of prerequisite skills would be indicated by scores of at least 60%. On the Knowledge Test, 77% of students did not reach the 60% level and 71% did not meet it on the Performance Test. At the other end of the spectrum, a few students performed well enough on the pre-test to be likely candidates for successfully challenging the course or taking courses that require skills equivalent to completing that course as a prerequisite. Obviously more testing and validity evaluation would be required to establish a standard for this, but in the authors' opinion, 80% seems like a level that would reasonably indicate mastery. If this were the case, 3% of students (1 individual in the pilot group) would have qualified. A summary report on the pilot test group performance on the pre-course tests was provided for informational purposes to the course instructors and senior teaching assistants.

**Full Implementation of the Tests**

The instruments were successfully incorporated into the regular offering of the course beginning in the Fall 2000 (approximately 1000 students). Validity and reliability tests gave similar results to the pilot test. In addition, the implementation of online testing substantially reduced the amount of time required to evaluate students, particularly in the Performance test. The data from these tests have established a baseline of data on the ICT skills and knowledge of students entering our Faculty of Education. We expect the average ICT skills and knowledge of education entrants to rise over the next few years. At some point a certain level of ICT Literacy could be an admission requirement. These automated instruments could be used as an efficient admission screening tool. The teacher education program could then focus more resources on improving teacher candidates' abilities to integrate technology into their teaching instead of development of basic ICT skills and knowledge.

Abstract: Two popular learning environments, TeleTOP and Blackboard, are implemented for specific educational contexts in many universities and other institutions. Goal is to increase the use of information and communication technology (ICT) in education, particularly network technology or Web-based systems. These electronic learning environments do not seem to differ a lot in functionalities and use. Also, the problems that instructors have to deal with are similar. Instructors must learn how to work with these new tools, and discover how they effect their education. Two similar best practice days successful experiences with functionalities offered and functionalities used by the instructors learn that instructors can make education as flexible (in time and place) for students, but should be aware of time consuming activities that cause dissatisfaction and frustration. The target should be that students should benefit from the added value of electronic learning environments, use functionalities that are useful for the students and the use is consistently.

Introduction

The inevitable expansion of the opportunities of technology and the growing awareness of the possibilities for using the technology in a specific educational context are causing many universities and other institutions to increase the use of information and communication technology (ICT) in education, particularly network technology or Web-based systems. In relation to this many organizations are using or starting to use electronic learning environments. Two of such learning environments, TeleTOP and Blackboard, are described here. After a brief overview of the general concept of an electronic learning environment the two environments will be described, considering the differences, but also the similarities between the two systems. Based on two similar best practice days the successful experiences with functionalities offered and functionalities used by the instructors will be described, concluded with some important outcomes.

Electronic learning environments

TeleTOP and Blackboard are two examples of tailor-made Web applications, also known as course management systems, virtual learning environments or electronic learning environments. Mirande, Riemersma and Veen (1997) give a very broad definition of an electronic learning environment. They describe it as a learning environment that uses technology. Jansen, Fisser, and Terlouw (2000) describe an electronic learning environment as an environment that supports and enriches the traditional environment by functionally using new forms of ICT. Droste (2000) defines e-learning platforms as the technical facilities that facilitate interaction in the learning process, communication, and organization. The three main characteristics of an e-learning platform in her analysis are that it contains a subject-matter section, a communication section and an organization section.

Electronic learning environment are thus comprehensive software packages that support some or all aspects of course preparation, delivery and interaction and are accessible via a network (Collis &
Moonen, 2001). Most electronic learning environments focus upon separate courses and do not collaborate with other systems such as the personnel database and a system for exams. It is believed that a system such as Blackboard or TeleTOP in combination with existing systems can offer a comprehensive electronic learning environment with one portal for instructors and students from which they can find all necessary information. However, this paper focuses on the electronic learning environment used in education. In the next sections TeleTOP and Blackboard are described as two examples of such an environment and a comparison between the two systems is made.

**TeleTOP**

TeleTOP is a course management system, developed at the Faculty of Educational Science and Technology of the University of Twente. Since 1997, the system has been developed and implemented. The implementation started at the faculty of Educational Technology and other departments soon followed (Collis & De Boer, 1999). At this moment TeleTOP is used throughout the University of Twente and is also in use in other Universities, companies and training settings. The core ideas to start building a Web-based environment were to support learning and make it more flexible. Furthermore the best of "old values of good teaching" and an attractive campus life with new didactics and advanced technologies were taken into account to optimize these new possibilities in learning.

The TeleTOP system was build upon a powerful database (Lotus Notes) and used by all staff members/teachers in the Faculty of Educational Science and Technology; it was made to be WWW-based (for both students as well as instructors) and it was made accessible through an ordinary Web-browser everywhere in the world. The TeleTOP system became a very easy to use system and it allowed to a certain extent fit with the instructional practices of an on-campus University and extent these to distance students as well. It also did engage change to new didactics. The starting-point was that WWW-based learning environments should not replace existing teaching and learning, but should add to them. As many systems TeleTOP is able to create and display all sorts of earning materials, as video, text, glossaries, web links, polls, quizzes, and so on. An important aspect of the environment is the Roster, a table-like environment in which study materials, assignment instructions, student submissions, and instructor feedback are integrated. This tool allows the instructor to model his course, create activities, relate assignments and study materials. It also helps instructors to think of effective ways to communicate with the students, and helps them to set-up the structural communication models.

**Blackboard**

Blackboard is the commercial electronic learning environment, developed by Blackboard Inc., which is used at the University of Amsterdam. Within Blackboard each course is delivered through a website. This website contains all the content and tools required to teach a course. Each course has an instructor who manages the course through the Instructor Control Panel.

For this article a description of the functionalities of and the experiences with CourseInfo v4.0 is given, the version of the electronic learning environment developed by Blackboard, which was used during the best practice day (see last section). The University of Amsterdam has been using this version since 1999, and is now migrating to Blackboard 5, Level Three, the software platform that delivers a course management system, with a customizable institution-wide portal and online communities and advanced integration tools and APIs to integrate Blackboard 5 with existing institutional systems.

**Differences and similarities**
Before taking a closer look at the actual use of two electronic learning environments, let's first look at some general characteristics. Table 1 shows the Differences and/or similarities of two of them: Blackboard and TeleTOP.

Table 1. Differences and/or similarities between Blackboard and TeleTOP.

Use of electronic learning environments in education, learning from experience.

In June 2001 a TeleTOP Best Practice day was organized at the University of Twente. A similar day was organized in September for Blackboard users at the University of Amsterdam. In both universities instructors were invited to present their experiences with the system in their education. There was a broad variety in instructors and courses, as instructors of different programs participated. In the presentations of the use of the electronic learning environments, instructors showed how the system was set-up, which functionalities were used, what goals were achieved and how this was experienced in the courses. The participants of both Best Practice days, all instructors also using the systems, were invited to nominate the presentation that they thought was the best example of good, useful and/or interesting use.

The best use of a TeleTOP site, selected by the instructors of the University of Twente, was a typical example of how electronic learning environments are used in the education at that university. Within the course the environment supports different students: students on campus and distance students who attend at face-to-face meetings every other Friday. Figure 1 shows a screen dump of the TeleTOP environment.

Figure 1. View of the Instructional Design course.

The instructor has used the environment to give a detailed overview of the schedule. A limited number of assignments were part of the course. The students could find these rights from the start of the course and were flexible in the submission of the assignments, though they needed it to submit for a fixed date. A part of these assignments were test in which the scoring and feedback was organized and given by the system. The instructors who liked this example, argued that the instructor managed to make use
of ICT in his education to make in as much flexible for students to participate, but also cared for his time, so it would not get out of hand.

The Blackboard course that was evaluated as best practice at the University of Amsterdam was the course “Design of modern foreign languages”, a course for students from the Graduate School of Teaching and Learning, in which the students have to make a design plan for a language course. Students participating in this course are regular on-campus students. Functionalities of the Blackboard learning environment that are used by the instructor to set up the course are Announcements, Course Information, Staff Information, Course Documents, Assignments, Communication and External Links. Students have their own tools as described in Table 1. This can be seen in Figure 2.

![Blackboard Course](image)

Figure 2. View of the Design of modern foreign languages course.

The options course information and assignments are the two options that are used most extensively. Students are informed about the course in general, including the goals, the schedule, and the way of assessing and grading the products of the student. The students have to do seven separate assignments. These assignments lead to a ‘master test’, the final assignment. In this assignment the students have to apply all knowledge and skills that they have used in the previous assignments.

The way the instructor designed the course and the way the functionalities were used were not evaluated as extremely original, but as very useful and consistent for the students. The instructor showed that by using the course in Blackboard next to the lectures students can benefit from an added value, especially related to time and place flexibility.

Conclusions

It is interesting to see what the institutions in the Netherlands that have decided to start working with electronic learning environments experience working with these systems. On one hand institutions
decide to organise a full institution-wide implementation of these systems. On the other had we see that instructors are still struggling with the question how they should use these new flexible tools and how this will change their teaching. They are concerned with how they can use the opportunities and functionalities that will make their teaching and their students' learning more flexible, efficient and enriched. In those institutions were a clear innovation goal has been set, these questions are more easier to answer than when the instructors have to deal with this question themselves. However, despite of the differences in electronic learning environments we see that instructors are creative, eager to learn how to use the tools and like the new possibilities. It looks like that best practice days as we have described in this paper are very fruitful opportunities for instructors to exchange ideas. Most important outcomes of the recent best practice days at the University of Twente and the University of Amsterdam are:

- Make education as flexible (in time and place) for students as possible, but be aware of time consuming activities that cause dissatisfaction and frustration.

- Let students benefit from the added value of an electronic learning environment, use functionalities that are useful for the students and use them consistently.

Further research should clarify if, and how, best practice days focussed on the exchange of experiences with an electronic learning environment have effect on the positive use of electronic learning environments in current and future education.

A Multimedia Web-Supplement to a Course on Beethoven

Anthony Paul De Ritis, Ph.D.
Department of Music and Multimedia Studies
Northeastern University, Boston, MA, USA
a.deritis@neu.edu

Abstract: www.beethoven.neu.edu is the result of a faculty initiative sponsored by Northeastern University's College of Arts & Sciences, with a goal of understanding better the implications of technology upon teaching. This website was featured in the "Learning" section of the Boston Globe on July 15, 2001, and may be used as a case study for faculty, staff, and administration interested in developing web-based supplements to their classes. This session describes the content and design of the Beethoven web-supplement, its use of e-learning technologies, and an evaluation and assessment of its effectiveness.

Issues with E-learning

The Beethoven web-supplement attempted to grapple with a number of current e-learning problems and issues, a few of which are stated below:

- How can we better understand the implications of technology upon teaching?
- Do pre- and post-surveys shed light on students computing habits? Their acceptance of online learning methods?
- Do online pre-assessment tests enhance a students understanding of course material?
- Does streaming audio of musical examples relieve the stress on our university media labs costs and resources?
- Does an online gradebook, and the ability for students to monitor their grade progress throughout a course, diminish their grade anxieties?
- How much do students really know about multimedia plug-ins and are they really interested in using the Internet as an educational learning environment?

Description

The web-supplement to MUS 1145: Beethoven, was the result of a collaborative effort between Professor Anthony De Ritis, his undergraduate assistant, Aris Amanatidis, the Northeastern University EdTech Center, and the College of Arts and Sciences and Northeastern University. Originally developed in 1999, this course has been offered at the university on three separate occasions. The College of Arts & Sciences offered faculty an opportunity to develop web-supplements through a Faculty Development Grant that included about $7,500 of funding. This included a one-course stipend, a laptop computer, a digital camera and scanner.

This Beethoven web-supplement was developed partly as an on-line companion to Maynard Solomon’s book on Beethoven, the required text for the course. Each student purchased this text, and was expected to take on-line quizzes – one quiz per chapter (now often called “pre-assessment tests”) – that required the student to read material for class discussions prior to attending class. At that time, through Web Course in a Box, all quizzes were automatically graded.

This website consists of:
- Pre- and post-surveys for evaluation and assessment
- Syllabus
- Lecture schedule
- Description of in-class lectures, including class business, topics to be covered, due dates for readings and assignments, and a glossary of important terms.
- Online readiness assessment quizzes
- An asynchronous discussion forum
- An online gradebook
Welcome to Northeastern University's Online Classroom on Beethoven

www.beethoven.neu.edu home

Example lecture schedule

Outcome

This Beethoven web-supplement was featured in the "Learning" section of the Boston Globe in July 2001. This article, titled "The E-Learning Road" chronicled how universities need to be aware of the "disruptive technology" of the Internet and the web in order keep their student "clientele".

Clearly, students felt a personal pressure to be prepared for class. Because their chapter quizzes, after they were automatically graded, also included a time-stamp that was e-mailed to me, I was able to monitor who was prepared for class, and who was not. I found that my class lectures were more interesting, in-depth and had participation from a larger portion of the student body (there are sixty students in each of the Beethoven classes offered with this web-supplement).

Survey data showed that over 80% of our average Northeastern students owned a computer with Internet access, and that some students actually upgraded their personal home computer systems during the course in order to take advantage of the web-based services. In particular, students were very please to be able to access to all of the musical examples required for listening at their disposal 24/7 – instead of having to be held to the media library hours. In addition, I was able to customize an exact listening list that I felt important for each student (often these musical examples do not appear on a single CD purchase). Web-based streaming audio allows for the easy organization of supplementary musical examples, which saves time and money for both the student and faculty.

Relevance

www.beethoven.neu.edu is a case study that has been used for all university faculty, staff, and administration, for the impact of e-learning technologies on education. The success of this web-supplement has led the way for additional grant opportunities at Northeastern University up to $25,000, and has stimulated the development of hybrid-courses which consist of courses offered half "on-line" and half "in-class". In addition, Northeastern University has now examined a variety of possibilities of offering complete courses and degree programs online.
There Is Still Hope for ICT in Flanders Fields.
ICT in Education: the Use, Benefits, Barriers and Expectations as Perceived by Educators at Flemish Universities.

Department of Computer Sciences
Nathalie.Blocry@vub.ac.be

Abstract: In this paper we present the main research findings of a large scale investigation about the state of the art in ICT use for educational purposes in Belgium, and specifically the current situation in Flemish universities. The main focus is on user characteristics and the attitudes of educators. Questions asked include: How do educators use ICT in their teaching practices? How do they perceive the support given by faculties within the framework of overall university policy? Which problems and barriers do they encounter? By means of an online survey we collected opinions in order to unravel which factors play a role in the decision to adopt ICT. This investigation reveals how ICT is used in a non innovative way in Flemish universities.

Theoretical Background

Educators play a crucial role in the adoption and implementation of new technologies in universities. New means of transmitting knowledge are only used if they offer clear advantages with respect to the old familiar teaching methods and enhance flexibility, efficiency and effectiveness (Collis et al., 1999), means to cope with information sources (Veen et al., 1999), ways to develop individual learning paths (Gehl, 1996), better student-educator communication (Twigg, 1995) and responsiveness (Hatfield, 1997). Previous research indicates that teachers reveal a variety of attitudes towards the introduction of ICT:

<table>
<thead>
<tr>
<th>Attitude</th>
<th>Short description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Neutralitarian</td>
<td>Usually users of ICT as a tool</td>
</tr>
<tr>
<td>Booster</td>
<td>Unconditional believers and pioneers</td>

<tr>
<td>Oppositional</td>
<td>Technophobe, fearing encroaching on human values</td>
</tr>
<tr>
<td>Sceptic</td>
<td>Those waiting for clear results before engaging</td>
</tr>
<tr>
<td>Transformationalist</td>
<td>Those considering changes as necessary but studying ICT carefully before its implementation</td>
</tr>
</tbody>
</table>

Table 1: Categories of educators' attitudes (Source: Evans, 2000)

The fear of the unknown, the tendency to consider the existing situation as a good one, a feeling of solitude caused by a lack of support and knowledge, and a reluctance towards self reflection can influence these intermixed attitudes (Hagner, 2000). Collis et al. (1999) developed the 4E model to predict the chance an educator will adopt ICT, based on the following concepts: (1) environment, (2) (perceived) educational effectiveness, (3) ease of use and (4) (personal) engagement.
Evidently, institutional policy plays also an important role in the motivation of the educator. The university approach can be either top-down or bottom-up and based on different points of view (Collis et al., 1999). We quote (1) proactive (driven by image building and market share), (2) reactive (driven by response to demand), (3) transformative (student centred) and (4) speculative (driven by hope in improvement efficiency and/or effectiveness) professional contexts.

The barriers opposing the introduction of ICT in higher education were thoroughly investigated in The Netherlands. According to Veen et al. (1999) the most relevant ones, in order of importance, are: a lack of time, skills, adequate infrastructure, support and rewards.

Research objectives and methodology

Besides general computer use and training, the following themes were studied at six Flemish universities: the perception of university and faculty policy, educators' types of ICT use and attitudes towards ICT implementation, including perceived advantages and benefits. A self-administered questionnaire was delivered via a database driven website to all teachers in the humanities faculties (N= 2244). They belonged to the departments of arts, law, economy, applied economy, business, political and social sciences, communication, psychology, educational sciences and theology.

Results

Profile of the respondents

442 candidates completely filled in the questionnaire (approximately 20% response). Two thirds of the respondents are teaching assistants, one third lecturers. 61% of the respondents are male, 39% female. It is noteworthy that the male/female proportion is about fifty-fifty up to the age of forty. The age distribution is as follows: 20-30 51%, 30-40 21%, 40-50 15%, older than 50 13%. Female respondents are almost absent in the highest age category.

ICT skills and training

A very small fraction of the respondents is not able to handle computers, operation systems and general applications like word processing. Similarly, e-mail, digital information systems and internet applications are unknown to only a very small group (respectively 4.3%, 3.2% and 5%). The overwhelming success of the internet is not induced by educational puposes but used for research. CD Rom use is not frequent (as expected), except in situations where it is imposed by research. The consultation of electronic teaching media (databases, courseware, communication facilities, etc.) is not common. Merely 8.9% of the teachers use them daily, while 76% almost never or seldom get in touch with these media.

</tr>
</tbody>
</table>

Table 2: Use of internet resources, CD-ROM and electronic teaching material

These ICT skills are mainly acquired via personal study and practical experience. Mainly younger educators had specific computer training at school or university. On encountering problems they tend to rely on colleagues.
Influence of university and faculty

Both the general use of computers and e-mail is heavily stimulated by the university or faculty (73.5% and 76%). On the other hand, educators do not report receiving much support when experimenting with ICT for educational goals. Significant differences between universities exist.

<table>

<td>14.0%</td>
</tr>
</tbody>
</table>

Table 3: Stimulation by the university or faculty

ICT policy

Although all Flemish universities have official ICT policy plans and coordinators, only a part of the educators are well informed about these initiatives. Clearly, a lack of communication lies behind this.

<table>

</tr>
</tbody>
</table>

Table 5: Present use and objectives

The left half of table 5 must be interpreted with caution because it appears that many respondents are not aware of the distinction between the use of ICT as an help tool and its capacity as a learning support.

Motivation

When considering the motivations teachers rate as important and very important for adopting ICT in teaching environments, they mainly want to increase the effectivity of their education. Secondly, they intend to promote autonomous study, enhance flexibility and create new educational contexts by means of ICT. Thirdly, they are motivated by enhancing the students' motivation and stimulating contacts between student and educator.
Desired use in the future

Substituting traditional classes is very unpopular. A clear majority of the respondents do not want to replace lectures, seminars and exercises by ICT supported activities. They are more likely to use ICT to extend these teaching activities. As far as testing and remedying deficiencies are concerned it can be noted that about half the educators are not willing to apply ICT.
Barriers

When asked to point out the barriers for adopting ICT in teaching environments, the educators reported the following problems (in order of importance):

1. lack of time;
2. fear of loosing personal contacts with students (which surprisingly appears not to be age related);
3. lack of skills, manpower support and adequate infrastructure;
4. problems caused by technical items and software;
5. lack of interest of students;
6. high costs;
7. introduction of ICT felt as a bad educational evolution;
8. lack of university policy.

Only items (2), (5) and (7) refer to pedagogical aspects of computer supported education, the other are related to personal and materialistic factors.

Conclusions

This study shows that ICT is used in a rather non-innovative way in Flemish universities. The advantages of different technologies are well understood as far as communication, information gathering and distribution are concerned. But a vast majority of the educators surveyed do not grasp the rich possibilities ICT can offer in
supporting or improving their teaching practices. Moreover, the teachers investigated perceive many practical and technical barriers for a successful integration of ICT in educational settings. Universities should play a more important role in offering relevant information and stimulating educators, not only in a passive but in an active way. Possible "solutions" include: awareness raising, appropriate training and support - both technical and pedagogical - and new, strong policies with a long-term vision on educational renewal rather than a policy based on ad hoc decisions and actions.

There is still hope for Flanders Fields. Small groups of innovators are disseminating their knowledge and positive experiences to their colleagues and helping to influence university policymakers.

Abstract: Recent brain-based research has generated renewed interest in pedagogical practices of the classroom. This development has drawn attention to lesson plan development since the development of lesson plans guides the learning process of students. To address the "whole-brain" in the instructional process, technology application should be incorporated in lesson plan design since it can effectively activate attributes of both the left and right hemispheres of the brain. This paper will provide a brief review of brain-based research and link it to pedagogical practices in the classroom through the design and implementation of technology-integrated lesson plans to optimize learning. Following this discussion, the authors will discuss how the University of Houston-Clear Lake (UHCL) Preparing Tomorrow’s Teachers to Use Technology (PT3) Project integrates technology-integrated lesson plans based on brain research into the UHCL teacher preparation program to provide quality learning.

Introduction

Brain-based theory indicates that learning is a process of active construction of meaningful ideas by the learner in an enriched environment (Lowery, 1998; Wolfe & Brandt, 1998). Dake (1977) asserts that traditional pedagogical avenues address functions in the left hemisphere of the brain (e.g., verbal reasoning, logic, analysis) and not the attributes of the right hemisphere (e.g., intuition and simultaneity). Lowery (1998) concurs, identifying teaching methods such as lecture, demonstration and textbook narrative as only minimally impacting the many avenues to the brain and learning. Teachers should use multiple methods of instruction to stimulate both brain hemispheres to optimize student learning. Technology applications have this capability. In an interview by Tell (2000), Healy warns that educators are dangerously close to limiting the use of technology on low-level content when research indicates that technology can drastically impact teaching and learning, especially in the development of higher-order thinking skills. An effective lesson design, which can incorporate technology usage, helps students to explore ideas, acquire and synthesize information, and frame and solve problems (Seamon, 1999).

Brain Based Research And Its Implications On Classroom Practice

Brain-based research on teaching and learning impacts not only teachers' delivery of instruction, but also the students’ acquisition of knowledge and skills. Researchers (Caine & Caine, 1998; Wolfe & Brandt, 1998) caution educators not to use brain research as a template of prescriptive teaching strategies, but to use the general findings as a guide to direct teaching and learning practices. Brain research provides educators with a framework for developing optimal situations for meaningful learning. This framework identifies general concepts about quality teaching and learning activities and situations to ensure student learning. Chief among the concepts is the notion of having an "enriched" environment. Enriched environments required learners to engage in a variety of inquiries within powerful content contexts, thereby increasing the probability that students will construct meaningful knowledge and thinking capabilities (Lowery, 1998). The environment in which a brain operates determines to a large degree the functioning ability of that brain (Wolfe & Brandt, 1998). Because the brain strives to "make meaning" from its surroundings, a classroom with many stimuli gives students several opportunities for comprehension of knowledge and skills at higher levels of understanding.

The notion that the brain changes physiologically through the learning process is supported by Wolfe and Brandt (1998), who argue that educators must develop an understanding of the brain and its processes to support meaningful teaching and learning, while disregarding the fads and ambiguous programs. To do this, educators need to stimulate different parts of the brain (Perry, 2000). Neural systems when exposed to only one form of stimuli fatigue quickly and need to rest. For example, after only a few minutes of lecture, the brain seeks other stimuli. When constructing knowledge, the brain requires data that can only be obtained through
sensory perceptions. Show-and-tell teaching methods, such as lectures and textbook narratives, activate only a few of the many possible avenues to the brain (Lowery, 1998). The proper use of technology affords educators the opportunities to prescribe learning experiences in which students can experience multiple cultures, research planets in solar system, and converse with students on another continent, in a non-threatening way. The use of technology provides teachers with the ability to find and provide connections between new content and a variety of contexts, thereby giving meaning to material and concepts to be learned, since the brain does not effectively absorb meaningless data (Wolfe & Brandt, 1998).

Several studies (Carr & Harris, 2001; Haigh, 1981; Wolfe, 1998) indicate that quality lesson planning has a beneficial impact on the teaching and learning in the classroom. A lesson plan provides a sequential structure describing what and how specific information will be learned (Cruickshank, Bainer, & Metcalf, 1995). Educators should construct lesson plans that incorporate technology applications that can stimulate different parts of the learner's brain. Perry (2000) argues that optimal learning in a classroom occurs when teachers are able to activate the student's entire brain.

**UHCL PT3 Project**

The central focus of the UHCL PT3 Project, funded by the U.S. Department of Education, is to create an educational process in preparing teacher candidates to develop and deliver technology-integrated lesson plans so classroom students (Pre-Kindergarten to 12th grade) use technology in demonstrating mastery of lesson plan objectives. In its training methodology, the UHCL PT3 Project addresses brain-based researchers' recommendations of activating both brain hemispheres by using a two-pronged approach. First, the teacher candidates experience left and right brain stimulations through the training module activities. Teacher candidates work left-brained attributes in “pointing and clicking” the various links on the UHCL PT3 Website (http://pt3.cl.uh.edu); but engage in right brain development when evaluating lesson plans posted on the PT3 Website. The second ‘prong’ of the approach is helping teacher candidates identify software applications that can stimulate left and right brain attributes of classroom students. For example, software applications such as Inspiration and Kid Pix can encourage higher level thinking processes such as brainstorming, concept mapping, and webbing; but can also be used for math and spelling drill activities. After developing the technology-integrated lesson plans, teacher candidates deliver these lesson plans in their respective grade level classrooms during their internship assignments. These classroom instructions allow teacher candidates to experience first-hand the educational implications of brain based research, affecting the classroom students' learning as well as their own.

HDSL An e-education Hypertext Document Structuring Language

H. Delebecque
Supelec
Plateau de Moulon

Henri.Delebecque@supelec.fr

Abstract

The development of a set of educational web pages is a complex task, because it involves multiple abilities: to be a good content author, a graphist, an ergonomist, following the advice of the webmaster. Moreover, this task has to be redone every time an author (or the academic site in which his pages are included) change the graphical or the navigational appearance. Last, you cannot use the advanced mechanisms of HTML (which can help in managing styles and content), since they are not fully supported by most frequently used web browsers. Our goal is to propose a language to be used by professors, helping them to structure the content of their hypertext pedagogical documents, and to free them from all the other aspects. The definition of a set of web pages is done by describing both a structural model (using our HDSL language), and a graphical model (using completely normal HTML). Using this pair of models, our HDSL engine will build automatically the XSL conversion sheets able to convert any of the documents built using the structural model into (for example) web pages using the most currently accepted HTML. HDSL also offers capabilities of inheritance between structural models, which allows a professor responsible of a whole pedagogical web site to define a look and feel for it, and derive it according to the needs of the various authors writing the hypertext supports of their courses. Moreover, the HDSL engine is able to accept presentation models in specific languages other than HTML, such as PDF, WML,...starting from the content of a single document.

Context

Developing a coherent set of web pages to produce a pedagogical document is a complex task, since the pages can usually be described using multiple approaches. One can, for example, organize them by dividing the main subject into sections (introduction, chapters, bibliography, index,...), or classifying them by kind of information (pictures, sounds, icons,...), by author. This list is not limited, and you have often to use many of these classification criteria simultaneously. This leads you to handle a great number of heavily interdependent documents, like a real software project manager. But the content of web pages has a much more dynamic structure than the source files of a software project: to be pertinent, the content of a pedagogical document has to be frequently updated.

Moreover, one has also to give a coherent look and feel to this complex set of documents. This aspect is of great importance in a pedagogical context, since it allows students not to be bothered by presentation or navigational considerations. Unfortunately, one has also to do with content authors who can either be HTML fluent, and these will take a lot of time to elaborate their own look and feel, or on the contrary they may be completely focused on the content of their document, and they will deliver them in various formats.

Another problem is the ability to describe the page content semantics for search tools, either your own, or commercial ones. The keywords HTML offers with its meta tags are also too simplistic, since they lack the ability to describe the context in which they are used, and are attached to the whole document, when we need a fine grain semantic description. A powerful and semantically-based search tool is a fundamental mechanism for helping students to browse your document, and find the definition or explanation they are looking for.

The cost of managing a huge set of HTML documents could be greatly reduced by the use of advanced tools available in HTML 4 (Ragget 1999). For example, CSS styles sheets can be used to insure a homogenous look, navigation toolbar and menus located in frames to standardize the interface presented to the internet reader. Unfortunately, most of these advanced tools are not universally supported by web browsers, or by other medium specific presentation languages (PDF, WML, restricted HTML).
The HDSL Project

Almost all these problems can be solved by using our Hypertext Document Structuring Language, HDSL, based on XML (Bray, 2000), that allows to describe the structure of families of hypertext documents, independently of their presentation and the medium on which they are displayed. That language allows also to add semantics to the items of the document, either on their content, or on their usage (navigation toolbar, menu,...). Separation of contents and presentation in HDSL give the ability to describe the look and feel of the pedagogical document which is different from mixing them with contents, as done with HTML.

To achieve this goal, we propose a mechanism based on pairs of documents. For every subset of the pedagogical document (course, chapter, section,...), which has its own look and feel, the content author will supply a model using HDSL, which describes its different parts (required or optional, describing the contents or the relations with other documents,...). According to this structural model, the graphist will supply a presentation model, which organizes the look and usage of theses parts. This presentation model can use various presentation languages, standard HTML, reduced HTML (for text-only browsers, low-bandwidth clients,...), WML, PDF, or others, according to the medium used to display the document. Our HDSL engine will take all these models, and generates automatically as many XSL stylesheets as needed to produce «displayable» forms of the concrete HDSL document written by content authors, for every needed medium. It allows to use a unique version of the document that defines the content, which is of a great importance to insure the coherence of the various displayable forms.

The solutions XML currently offers, such as pure XSL sheets (Clark 1999), has multiple drawbacks: you have to fully master XSL, to write a XSL sheet for every presentation medium, for every subset of your pedagogical document. Moreover, this XSL writing task must be redone every time you change the look and feel. And this way of producing web pages doesn't allow re-utilization or genericity which our tool includes, nor any possibility for handling interrelations between documents. It doesn't provide either any may to manage the versioning of the document the HDSL engine supports, and which is of great help in managing the production of many contents author.

Related Work

The WebML language (www.oasis-open.org/cover/webML.html) is a notation for specifying complex Web sites at the conceptual level. It allows the description of navigation and composition abstractions, which are assembled into pages and interconnected by links. WebML is devoted to the construction of web sites based on very dynamic information fetched from multiple databases, and linked by complex relationship, described using E/R model, ODMG object-oriented model in a structural model. The presentation model defines the appearance of pages, independently of the output devices and the rendition language, like HDSL, except for the data described in the structural model. The application domain of WebML is rather e-commerce oriented sites than educational or academic ones.

The Percussion's products (Rhythmyx Content Manager) (www.percussion.com) is a commercial set of tools, devoted to the management of web pages by the content authors, without asking them to mastering HTML, or even site rules and structures. It allows the same information to be presented in multiples pages, as HDLS does, and clearly allows the separation between content and presentation. But it is a relatively cumbersome tool, more dedicated to commercial sites than educational or academics ones. HDSL, on the contrary, is a rather straightforward tool, which pushes the versatility of XML in domains such as the expression of the content semantics. Percussion also develops a XML to HTML tool, Xsplit, but which presents only some of the capabilities of HDSL.

Abstract

This paper describes the first stage of a four year research project on the design, development and use of web based digital learning material for food chemistry education. The paper discusses design guidelines, based on principles that were selected from theories on learning and instruction, and illustrates in detail how these guidelines were used for the design and implementation of digital learning objects (LO). Six cases, a set of presentational LO and a dozen interactive exercises have been designed, developed, implemented, and imported in different learning environments. The design guidelines proved to be useful during the design process. The digital learning material has been evaluated positively by students and lecturers. The material forms now a set of inspiring examples for food chemistry in higher education.

Introduction

The Food and Biotechnology (FBT) programme is a research programme on design of digital learning material. The programme was initiated at Wageningen University in September 2000 and currently counts 5 large projects. The digital learning objects (LO) that are developed within the FBT programme should meet the following requirements. First, the quality of the learning material must be considered highly satisfactory by experts in the respective fields as well as by students. Second, it must be possible to manage the LO with the mainstream Learning (Content) Management Systems (LMS). Third, the LO must be useful in a wide range of different instructional settings in higher education. Finally, the development costs for one credit point (one weeks study) material should be within the 60.000 $ (US).

Within the FBT programme a four year research project on the design, development and use of web based digital learning material for food chemistry education is carried out. Food chemistry is a disciplinary science, which masters and generates knowledge and insight mainly related to a) components of food, b) (bio)chemical reactions occurring in food, c) effect of treatments on (bio)chemical reactions and d) quality characteristics of food. The challenge of the project is to select and experience with design guidelines, taken from different disciplines in order to design effective LO for food chemistry education.

Theories on learning and instruction offer important clues to design effective learning material, including digital learning material. In particular there are good textbooks on course design and instructional design (Posner 1997, Smith 1993, Merrienboer 1997). Furthermore, there is much research on effectiveness of computer assisted learning. This research is mostly conducted in a laboratory context where a number of practical constraints can be ignored. On the other hand, much literature describes the use of digital learning material in practice. Nevertheless, practical detailed guidelines for the design of LO within realistic budgetary limits, which also satisfy technical and organisational constraints, are missing. In fact, there is a strong need for paradigm examples for specific scientific disciplines such as food chemistry.
The work presented in this paper describes the design guidelines for digital learning material for the introductory course Food Chemistry, which is a 4 credit point course for second year food technology students at Wageningen University. Material has been developed to support two, for this course, important learning objectives: acquisition, construction and retention of (declarative) food chemistry knowledge and a quantitative understanding of the relative importance of the chemical reactions occurring during food processing and storage.

The next section presents which pedagogical principles were selected. Section 3 describes how a set of digital LO have been designed and developed according to guidelines based in the selected principles. Section 4 gives the evaluation of the use of the LO by students and lecturers.

Selected Design Principles

From theories on learning and instruction, five principles were selected as the basis for every LO. This selection was based on three selection criteria. First, the selected principles are relatively insensitive to changes of educational or instructional concepts. Second, the need to reduce cognitive load was especially considered relevant for food chemistry, where the amount of detail is initially overwhelming for many students. Finally, the selection focuses on the strong points of digital material as compared with lecture notes. The principles are not completely mutually independent. The principles are:

a. Aim at optimisation of cognitive load
Cognitive load is the demand placed upon a person's cognitive abilities when performing a task. Effective training should reduce the cognitive load, since learning is typically constrained by limited processing capacity (Merrienboer 1997). Ignoring this principle will reduce the students' confidence. Digital learning material provides more possibilities to reduce cognitive load than lecture notes.

b. Aim at motivation of students
Motivated students learn better, faster, and more and also remember better (Schmidt 1998). According to the ARCS model (Keller 1988) instruction should capture the Attention of the student, should be perceived as Relevant by the student, and should induce Confidence and Satisfaction, to motivate students. From this principle many guidelines for the design of learning material can be derived. Digital material provides new options for motivation (Malone 1987).

c. Present information Just In Time (JIT)
Providing information just prior to application is a form of Just-in-Time Education (JiTEd)(Hudspeth 1992). An advantage of JiTed based learning material is that the cost of learning is directly turned into benefit. JIT-information is also an instrument to prevent cognitive load as well as to motivate students. It is important to be aware that students who work with digital material expect JIT presentation, since they know that JIT presentation is one of the strong points of digital material.

d. Visualise whenever possible:
There is much evidence suggesting that retention of knowledge will be enhanced when images accompany words (Denis 1994). Additionally, images will often increase quick understanding and reduce cognitive load (Anderson 1995, Larkin 1987). Lecture notes seldom take advantage of presentational formalisms other than printed text and formulas. Visualisation in digital material is ultimately cheaper than in lecture notes.

e. Activate whenever possible:
Students should be activated to elaborate on recently acquired declarative knowledge. Evidence is found that practice or elaboration on a subject strengthens the retention and the retrieval of the subject (Anderson 1995) as well as understanding. Better retention reduces cognitive load in later stages (Merrienboer 1997). Clearly information and communication technology offers much more possibilities to activate students than lecture notes.

Applying Design Principles within Food Chemistry Education

Digital material is designed according to several criteria, for instance the intended learning objectives and the requirements of the FBT programme, which are all considered as important to design successful digital learning
material. The above mentioned design principles are translated into design guidelines that match with the other criteria. The design guidelines are therefore different for different kinds of digital learning material.

**Presentational Learning Objects and Interactive Exercises**

Presentational learning objects (presentational LO) and interactive exercises have been designed to support the acquisition, construction and retention of (declarative) food chemistry knowledge.

A typical example of presentational LO or interactive exercises is shown in the figures 1 and 2, which display two parts of one interactive exercise (see Demo Site). In this exercise students first have to look at the molecule of anthocyanin (a natural colorant). By moving the mouse pointer over a specific part of this molecule an explanation of a specific property pops up. Figure 1 shows the situation where the mouse pointer points at a place that is known to make a complex with a multiple charged metal ion. When students have read the information they can go to the exercise. This part, which is shown in figure 2, is based on the game mah-jong. The student has to click two pieces that belong together and press the OK-button. If the two belong together the pieces disappear. The goal of the game is to get rid off all pieces. The information linked to the molecule in the first part is related to the words on the pieces in the mah-jong game.

Table 1: Design guidelines specific for the design of presentational LO and interactive exercises

To minimise cognitive load the presentational LO and interactive exercises are small, complete and powerful. The LO are small since they are designed to take at most 30 minutes. In the case of the anthocyanin example, the whole exercise will approximately take 15 minutes. Second, the LO are independent and support the construction or the elaboration of a complete and distinct piece of knowledge. For instance, the example deals
only with those properties of anthocyanin which are important for the stability of the molecule. The third way to
minimise cognitive load is by using powerful key-symbols that explain the situation in a direct way. For
instance, different parts in the molecule structure of anthocyanin (Fig. 1), the key-symbols, are highlighted (see
Demo Site). Every student will understand that the information linked to a part belongs to that specific part of
the molecule. This is essential to explain something without using words. The advantage of the natural
relationship between (part of) an image and the meaning of that image is used in all LO and exercises.

To motivate the students, the range of different types of LO and exercises is large (see Demo Site). Different exercises are for example: a) choose the right option between two options, b) choose between several
options, c) match propositions d) complete chemical reaction pathways by dragging molecules to the right place
in the reaction, e) choose between different areas in a graph with different reaction rates, and f) complete the
construction of a molecule by dragging the right component to each molecule. Examples of different
presentational LO are: a) movies explaining or showing reactions, b) molecules that give information when
clicking on it, and c) small, easy exercises providing additional information.

Another important tool to motivate students is by incorporating games (Malone 1987). The exercise in
figure 1 and 2 is a typical example of a game. Several exercises have a game-like appearance.

JIT-presentation of information is mainly provided in two ways. First, the interactive exercises have
links to corresponding presentational LO. In this way, students can easily look up information to answer a
question or learn more about the subject. Second, like in the anthocyanin example, necessary information is
presented within the LO.

Visualisation is an important part of the presentational LO and interactive exercises. Within these LO
colour is used in a functional way, especially to highlight important elements. The visual LO vary from static
pictures — for example a molecule or a photograph of a fruit — to animations and screen recordings — for
example an animation of a chemical reaction in detail —. The use of text is minimised. Again the anthocyanin
exercise is a good example.

The presentational LO and interactive exercises induce active behaviour. Both figures 1 and 2 show
how students can be activated. In the first part of the exercise (Fig. 1) the student will only learn something
about the molecule if (s)he points the mouse pointer at the molecule. The student is forced to pay attention to
what (s)he sees and reads. In the second part of the exercise (Fig. 2) the student is activated to play a game and
probably this activates the student to go back to the first part to study those parts (s)he didn't remember. In all
presentational LO and exercises students are forced to do something: mouse-over actions, click the mouse,
move objects, fill in numbers, answer short questions, play a game, etc.

Digital Cases

Digital cases have been designed to promote the transfer of knowledge of mathematics, reaction kinetics and
reaction equilibrium, which students already acquired in previous courses, in order to be able to translate
practical problems within Food Chemistry to arithmetical equations and to solve them. The intended learning
outcome is a quantitative understanding of relative importance of reactions occurring during food processing
and storage.

The digital cases are divided in a presenting and an activating part. The presenting part contains all
necessary information about e.g. reaction kinetics and information about working with Excel. This information
is structured in one place, which is denoted a library. The activating part exists of six different cases. Every case
applies a certain concepts in the field of Food Chemistry, for example the hydrolyses of saccharose (sugar) in a
fruit drink. On average, each case contains 10 guiding questions. The first questions (2 to 3) are introducing the
subject, asking about basic knowledge necessary to understand the topic of the case. The following questions
are mainly about making calculations or graphs, and they require for instance to fill in a (calculated) number or
an interpretation of the calculation/graph. Calculations are assisted by the information in the library and by
feedback and hints. The most important design guidelines for the digital cases, based on the principles in section
2, are listed in table 2.

The activating part within each case is built around a practical situation. For example, the student plays the
role of a researcher who has the task to solve a problem in a company. The calculations on chemical reactions,
kinetics, etc. are leading to a solution of the problem or a clarification of the situation, which shows the
usefulness of the calculations.
Principles | Design Guidelines
--- | ---
Minimisation of Cognitive load | - Provide only necessary information
 | - Minimise search for information
Motivation of students | - The student plays a role during the case
 | - Show the usefulness of calculations
 | - Give the student a feeling of independence
JIT presentation | - Provide hints/feedback/introductory questions
 | - Provide movies on how to work with Excel

Table 2: Design guidelines specific for the design of the digital cases

The introductory questions have the objective to activate (make available) prior knowledge. The availability of much relevant prior knowledge improves the learning capacity (Schmidt 1998).

To minimise cognitive load, only necessary information that students need to calculate on reaction, like formulas, is provided in the library. Because students have to use some advanced tools of Excel, the library also contains information in the form of audio visual screen recordings. The students can put the information from the library immediately into practice, which is a form of JIT-presentation.

Cognitive load is also reduced by minimising the search for information, which is needed to solve a question within a case. Therefore, questions contain hyperlinks that point to specific information in the library. Also background information about food chemistry, for example, why a product turns brown during heating, is provided when needed. Especially the introductory questions refer to background information. Both the links and the background information are a form of JIT-presentation.

The information, the links to the information and the hints are applied in such a way that a student should be able to finish a case without the help of a teacher. The hints help students to work towards the solution. Students can ask for a hint themselves, but after submitting an incorrect answer a hint is given automatically. Also, after submitting an answer feedback on the answer is given. This will probably give the student the feeling that (s)he is able to solve the case by him or herself, which strengthens the student's self-confidence and satisfaction.

Evaluation of the Design Principles within Food Chemistry Education

The students used and judged the digital learning material during the time of the course. Table 3 gives some results from questionnaires students had to fill in after using the digital learning material. The results are categorised according to the principle they represent. Not all principles were evaluated, since some guidelines do not need to be judged by the students; these guidelines were just used by the designer.

It seems that the success of the digital cases is due to the JIT-presentation of information like hints, links to the theory, and feedback. Because of this information students seem to learn faster, to be more self-confident and to be more motivated to solve the questions.

The results of the questionnaires for presentational LO and exercises strengthen the belief that it is very well possible to provide knowledge by mainly using visuals accompanied by a minimum of textual parts, especially for explaining reactions or explaining intricate events in food chemistry. For food chemistry, visualisation of different aspects is a strong tool to help students understand and remember the sometimes intricate information.

For the designer, the guidelines, which are described according to theories on learning and instruction, supported the design of digital learning material based on theories rather than based on common sense. The guidelines keep the designer on the road during the project. Every piece of material that was designed and developed was judged to be parallel with the guidelines and principles. Although it is not easy to test if the principles are correctly implemented there has been no indication of the opposite.

The pedagogical principles seem to be translated successfully in guidelines that were used to design digital learning material. By this, a set guidelines based on general accepted principles are described that are useable in different educational settings within food chemistry and related settings.
### Final Remarks

During the academic years 1999/2000 and 2000/2001 the digital LO were evaluated. Both students and lecturers judged the digital LO positive. The digital LO will now be used as an inspiration for faculty staff. Because of the independent character of the LO they can be imported in a range of different LMS such as Blackboard and Hyperwave ELS. The proof of the principle that it is possible to design and develop a rich body of LO for food chemistry, which satisfy the design criteria described in the introduction, is close at hand. Further research will be directed to articulation of design criteria for digital LO in food chemistry based on a match between intended learning outcomes of food chemistry courses and the possibilities and limitations of state of the art digital LO. This should be a first step towards a methodology of digital learning object design for food chemistry and to a handbook of best practices.

MEDICAL EDUCATION: A MULTIMEDIA ENHANCED BLACKBOARD COURSE

Melissa Diers, M.A.
Information Technology Services, Learning Environment and Internet Services
University of Nebraska Medical Center
United States
mdiers@unmc.edu

Barbara Heywood, M.D
Otolaryngology - Head and Neck Surgery, College of Medicine
University of Nebraska Medical Center
United States
bheywood@unmc.edu

Abstract: The University of Nebraska Medical Center is a leader among the US Medical Schools with graduates who choose Primary Care Medicine. The ability to accurately diagnose an ear disease is an important skill of a Primary Care graduate. Prior to graduation all medical student receive didactic lectures covering ear disease. Upon inquiry the Department of Otolaryngology found that 30% of the students graduate with clinical “hands-on” experience of diagnosing ear disease. A Blackboard course was created to give the students an opportunity to experience diagnosing ear disease by offering a patient-based course with supporting visuals. The course creation, successes and failures will be discussed. A course demonstration will occur during the presentation. The instructional design and the demonstrated ability to create a course that is multimedia rich without a heavy commitment to programming with html are points of interest.
student. The third year of the curriculum consists of six required clinical clerkships (Internal Medicine, Family Practice, Surgery, Pediatrics, OB/GYN, and Psychiatry). The fourth year of the curriculum consists of a required basic science elective and eight electives. Within the third or fourth year, with the input of an advisor, the student is required to select a primary area of interest. Upon the selection the students is required to choose five of eight electives from their primary area of interest (out of the 8 electives). These primary area electives have been determined to be appropriate for students entering that field. The remaining three electives can be chosen from any other primary interest area.

During the third year of the curriculum, traditionally only 30% of the medical students have selected Otolaryngology – Head and Neck Surgery during the Surgery clinical experience. During the second and third year of medical school a student attends a minimal number of hours of didactic instruction covering Otolaryngology – Head and Neck Surgery. This analysis was very helpful prior to researching and writing the content, acting as a barometer to set the level of content. The audience analysis highlighted the importance of closely simulating the traditional clinical experience.

Prior to being the course creation process, some instructional design aspects were identified. In effort to mimic the clinical setting a patient-based model was selected for the construct of the course. The course includes video of the ear examination, supporting still images, test results and the patient’s history. The video examination is an essential piece of the instruction that exhibits the technique of using the examination instrument, orientation within the human anatomy, and the ability to show specific characteristics to aid the process of ear disease diagnosis. The students will be instructed to participate in the course via the campus network or a high-speed Internet connection. An alternative option of writing the multimedia to CD-ROM and distributing the CD-ROM to off campus (non-networked/modem based) students is being assessed.

Once these instructional design aspects where identified the faculty member began the research of content and capturing supportive multimedia as each the ear diseases were diagnosed and treated in the clinic. The faculty member obtained consent forms from patients, outlining the rights to summarize the patient’s case and to capture necessary multimedia (digital images, video of examination, and test results).

Each level is supported with the multimedia, patient history and examination and the student is instructed to complete within a 15 to 20 minute interval. During the course creation process some message design issues addressed.

The overall structure of the course consists of eight levels of severity of the ear disease diagnosis based on physical findings. The students can work through the entire course or to jump to the desired content, offering the just-in-time training. Simple buttons and hyperlinks were constructed in Blackboard to create these two options. During the creation process, the message design was modified numerous times. The final design includes patient history, examination, still images, and a video ear examination.

Other elements of interest are prescriptive instructions, the importance of limiting the students’ expectations, and the ability to create an online multimedia rich course without a heavy commitment to programming with .html (the language of the internet).
Following Faraday's steps at high school, using microcomputer based labs.

University of Athens, Pedagogical Dept. P.E., Navarinou 13A, Athens, GREECE

Abstract
The new information technologies can create a more productive educational environment for physics teaching. In this paper we describe the use of microcomputer based labs (MBL) for the studying of electromagnetic induction. In MBL labs, the students—by participating in hands-on experiments—have the opportunity to measure, directly and simultaneously, the physical quantities that are involved in the induction phenomenon. The computer, equipped with an interface and sensors, serves as a measurement device. From the evaluation of the learning outcomes we can deduce that there is a major contribution to students' understanding of the physical concepts and laws.

Introduction
Today, more than any other period in the past, and due to the exponential growth of technological progress, people are greatly influenced by the development of scientific knowledge and the advancement of information and communication technologies. The relationship between science-technology and education is far more complicated today than any other time in history. Nowadays, there is a close relation between science and technology, where both fields share a constant feedback process. The expansion of scientific knowledge leads to new technological applications, while technology provides scientists with tools, techniques and devices that allow expansion of their capabilities and effectiveness, thus leading to a further development of science. Yet, as technology gets more and more complicated, there is no sharp boundary between science and technology since the area of their overlapping gets constantly wider.

Traditionally, the teaching of science and technology in schools focused mainly on providing the knowledge of theories and facts or the attainment of technical skills. This mechanistic approach of teaching does not represent neither an effective nor an appropriate strategy towards science-literate and technology-literate pupils. So, there is a growing necessity to develop a new educational environment that will allow students to collect, visualize, analyze and model the experimental data so that they will be able—through their active involvement and participation—to understand the laws of physics and the present relationship between science and technology. A new suggestion that will facilitate the attainment of the proposed objectives is the use of microcomputer-based laboratories (MBL labs) in education. In a MBL lab students do real experiments not simulated ones, using sensors connected to a computer via an interface.

Subject/Problem
The phenomenon of the electromagnetic induction holds a significant and central rank not only concerning its connection with the development of classical physics, but also with the technological utilization of a major physical discovery that led to the production of electric energy—a process that had a radical impact in modern civilization. Furthermore, it gives us the opportunity to understand the function of devices that transform mechanical energy into electric energy and vice versa, like electric generators, motors or transformers.

The traditional instructional approach to the phenomenon of electromagnetic induction is substantially limited in the repetition of the experiments conducted independently by Michael Faraday and Joseph Henry in the middle of the 19th century—a practice which is followed by the sudden and inexplicably appearance of the Faraday's law of induction, that relates the induced emf with the rate of the magnetic flux change. But, naturally, the vast minority of children cannot follow Faraday's exemplary line of reasoning that led to the statement of the law of induction. So, they just memorize the law with no functional understanding of it and without having the opportunity to apply it at real-world situations or problems.

A laboratory approach, based on the new information technologies, could contribute to the improvement of the educational outcomes concerning the principles of electromagnetic induction and Faraday's law. More specifically, the use of sensors for collecting voltage and magnetic field measurements and the real-time display of this data in graphs presented at the computer screen, permits:

- The direct measurement of the strength of the magnetic field—something especially difficult to be done with the use of traditional devices—but without which, one cannot experimentally discover and verify Faraday's law.
- The comparison between the change of the strength of the magnetic field and the induced voltage.
- The focus of students' interest in the development of the phenomenon.
- The detection of students' preconceptions and the use of socratic dialogues between teacher and students throughout the experimental procedure.

Design and procedure
By utilizing the new information technologies we designed and applied an instructional intervention for the phenomenon of electromagnetic induction at the laboratory by connecting sensors through interface with the computer. The procedure involved the historical induction experiments of Faraday and Henry. Three high schools in Athens were selected to be school units of application, so that the sample would represent the average Greek high school student. 75 high school students of the 12th grade from 3 different school classes (of vocational-technical education), participated in our research. The students had already been recently taught about the induction phenomenon, through the traditional instructional method.

Two experimental activities were conducted. In the first one, we used a coil and a magnet that was moving relative to the coil, while in the second we used two coils wrapped around a soft iron core. With the use of a voltage and a magnetic field sensor—we obtained a real-time collection of the corresponding data and a graphical display of their change with time at the computer screen.

The first learning outcome was that students realized than an induced voltage in the coil occurs only during the movement of the magnet and that the polarity of the voltage depends on the direction of the magnet's movement, whereas, with the magnet inverted, the changes of the induced voltage with time vary accordingly. From all the above, students came to the conclusion that polarity is determined by the absolute value of the magnetic field change. Next, the students started wondering about the factors that determine the magnitude of the induced voltage $V_A$ and concluded that $V_A$ does not depend simply from the change of the strength of the magnetic field, but from its rate of change. By using printed-out diagrams, each student would calculate the slope of the curve that shows the voltage versus time; in other words, they would calculate the rate $\frac{dB}{dt}$ at the peak of the voltage waveform. Next, students determined the ratio $\frac{V_{in}}{dB/dt}$ and realized that this ratio remains constant or that the induced voltage is proportional to the rate of change of the magnetic field strength, i.e. with the rate of change of the magnetic flux. Finally, the fact that the induced voltage is proportional to the rate at which the magnetic field changes (i.e. to the rate of change of the magnetic flux), was
also verified by the students through the software which allows the simultaneous screen display of how $\frac{dB}{dt}$ and $V_m$ vary with time—a display that gives students the opportunity of a direct comparison between the two.

In the second experimental procedure we used three sensors at the same time. The first sensor was measuring the strength of the current, the second the strength of the magnetic field, and the third was taking measurements of the induced voltage in the second coil. The learning outcome was that the student understood (or realized) that an induced voltage is produced in the second coil when the strength of the electric current varies with time and that the voltage magnitude is proportional to the rate of change of the current in the first coil.

Results

Before the instruction, students were given a pre-test that consisted of several close-typed multiple-choice questions and they were asked to fill-in some sections of a diagram. Two weeks later, after the instruction, students were given a post-test, that consisted of similar style questions with that of the pre-test, but of higher difficulty level.

The results are shown on Table I. They show three basic elements of the electromagnetic induction phenomenon, namely the reasons for the production of emf, the polarity of the induced voltage, and Faraday’s law. The table illustrates the percentage of successful students’ answers concerning their conceptual understanding of these subjects.

Table I

<tr>
<td>Faraday’s law</td>
<td>20</td>
<td>51</td>
<td>31</td>
</tr>
</tbody>
</table>

Results of pre- and post-testing of students' conceptual understanding of electromagnetic induction

As we can see from the obtained results, the reasons for the production of emf are well-understood by the students even through the traditional instruction. But, with the use of MB-labs there is a substantial improvement on the results concerning the polarity of the induced voltage and the connection of its magnitude with the rate of change of the magnetic flux. Gain is observed mostly on those features that are illustrated more thoroughly through the graphical transformation of the data into time-varying diagrams (for example, the slope of the curve represents the rate of change of the corresponding physical quantity).

Furthermore, student course evaluation and comments by students show the MB-labs have been very well received.

Discussion

In spite of the extensive implementation of MBL—programs in the teaching of Mechanics, the relevant literature about their application in the study of electromagnetic phenomena is very limited and it is characterized only by the indirect verification of Faraday’s law of induction. From the results of our research it is evident that MBL-labs serves as an effective tool for the development of a good conceptual understanding of the electromagnetic induction. Our research supports the view that the utilization of MBL-labs assists students’ ability to describe, understand and predict the development of physical phenomena. Similar conclusions have been reached from the implementation of MBL-labs for the teaching of other content areas in junior and high school students.

Our research team aims at the expansion of MBL-labs utilization into other phenomena included in the junior and high school science curricula. A wider and more general application of the microcomputer-based laboratories in various content areas and school grades, may be the key factor for the necessary reform that aims in boosting students’ interest and improving the effectiveness of science teaching.

DESIGNING A MASTER OF SCIENCE ONLINE DEGREE PROGRAM

Rita L. Dobbs, Ph.D.
W. Clayton Allen, Ed.D.
Department of Technology
The University of Texas at Tyler

Abstract: This session will include critical information for administrators and faculty in higher education to develop and implement an on-line master's degree program in Technology/Human Resource Development. Students enrolling in the MS degree program can pursue the Master of Science in Technology/Human Resource Development degree or students can add Trade and Industrial Teacher certification to their degree plan or they may elect to complete only the T&I Teacher Certification portion of the program without pursuing the Master of Science degree. The degree program is offered through The University of Texas TeleCampus which provides a virtual university setting complete with library resources, student support, and tutorial help for participating students.

Today's information technology and instructional telecommunications enable the U. T. System to extend its collective educational reach to students in Texas and beyond through the UT TeleCampus, an Internet-based central support unit for distance education. The UT TeleCampus was launched in May 1998 as a central support system for the online educational initiatives of the 15 component campuses and research facilities that comprise the U. T. System (UT TeleCampus). Extensive support services are provided by TeleCampus staff in the way of instructional design and course development, as well as faculty training in bringing courses from the lecture-based classroom to the Web-based classroom. Technological support, policy, marketing research and external communications are among the other essential support services provided to the campus from the UT TeleCampus (UT TeleCampus).

The goal of the TeleCampus in placing programs online was the creation of collaborative degrees, utilizing the best resources in faculty expertise from all campuses (UT TeleCampus). This was the model followed in developing the Master of Science Degree in Technology in Human Resource Development (HRD).

Overview

The Department of Technology, in support of the mission of The University, is a student-centered department committed to conducting multi-option programs targeted at preparing technical professionals, and educators. In developing this online degree program, the department is further supporting the mission of the institution that will "establish the university as a leader in the teaching and use of informational technology." Providing a Master of Science degree in Technology in the Human Resource Development (HRD) option in an online format so that it is accessible to all the citizens of Texas and beyond will achieve the mission of The University of Texas at Tyler and the Department of Technology. In the proposed third year of the phase-in program, additional courses will be developed to enhance the HRD option and complete the State Board of Educator Certification (SBEC) Trade and Industrial (T & I) certification to help address the critical shortage of teachers in this discipline.

Human Resource Development is a professional field of practice that focuses on education and training of adults in diverse settings. It is organized learning activities arranged within an organization in order to improve performance and/or personal growth for the purpose of improving the job, the individual, and/or the organization. HRD includes the areas of training and development, career development, organization development, adult literacy, and distance education.

The online Master of Science degree in Technology with the Human Resource Development option will utilize the resources of The University of Texas at Tyler, The University of Texas at Galveston (UTG), The University of Texas at Permian Basin (UTPB), The University of Texas at Arlington (UTA), and the UT TeleCampus. The Department of Technology will assume responsibility for developing six courses in the major of the degree option and will utilize existing component online TeleCampus courses to round out the degree requirements in the major and support areas. The degree offers access to higher education attainment by professionals in the field by flexible scheduling and asynchronous delivery. In the
proposed optional 3rd year of the program, UTT will develop the three additional courses needed to complete the T&I certification program for Texas teachers in the trade and industrial discipline, and the courses will be utilized to strengthen the HRD degree option.

Benefits

1. A major benefit of this online degree is the meeting of the increased demand in business and industry for personnel trained and educated in the human resource area. By providing the access necessary for adult learners, the demand for a highly skilled workforce can be met.
2. Another benefit of the degree is to meet the unique needs of the adult learner, the nontraditional student, and the geographically bound student. The elimination of time, space, and boundaries allows The Department of Technology to meet its mission and the mission of the institution.
3. The cooperative nature of the degree program allows each component institution to leverage its strengths while at the same time minimize the inability to offer every course that is necessary in developing a quality degree option. The increased visibility of each component makes it a win-win for all participants.
4. The online degree is now the standard vehicle for attracting and retaining the student population that today has more options for higher education selections than ever before.
5. The online degree will allow The Department of Technology to continue to serve students in remote locations who have been previously served by interactive television courses being phased out of the institution because of cost-cutting measures and increased line charges.
6. The online degree provides three of the six courses needed for trade and industrial teacher certification in public schools, an alternative certification program in a high demand area in the state.
7. In the third year of the grant program, the final three courses needed for trade and industrial certification will be developed helping meet the demand for teachers in this discipline.

Summary of Program

The Master of Science degree in Technology with the Human Resource Development (HRD) non-thesis option is a 36 semester credit hour degree program requiring two three semester credit hour core courses, Research Techniques and History and Philosophy of Technology, 18 semester hours in the area of concentration of HRD and 12 semester hours of support courses. During the last semester of the program, the candidate must successfully complete a written and/or oral comprehensive examination on the coursework of the degree plan.

The program is administered by The Department of Technology, The University of Texas at Tyler who will serve as the degree granting institution as authorized by the Texas Higher Education Coordinating Board. UTT personnel will develop 6 courses to be used in the major of the degree in a two-year period. Identified support courses will come from the components of UT Galveston, UTPB, UTA, and UTT and other online TeleCampus courses.

Students must meet the admission requirements of UTT graduate school as outlined in the current catalog that can be accessed at www.uttyler.edu.

Students completing the certification courses must meet the requirements of the State Board of Educator Certification for T&I teachers. Current guidelines for this program can be accessed at their web site of http://www.sbec.state.tx.us/certreq/certreq.htm or through the Texas Education Agency web site for Career and Technology at http://www.tea.state.tx.us/Career/ti/index.html.

Abstract: Why do so many instructional design projects struggle? Perhaps one reason is that the projects are managed by instructional designers who have little project management experience. Experienced instructional designers frequently perform the role of project managers yet ID graduate programs rarely require project management courses. Even instructional designers who are not officially “project managers” need to manage projects, their own or those with other team members. Often, however, they have no training in project management.

Introduction

If an instructional designer does not have training and experience in project management, both the project and the instructional designer will suffer. Students enrolled in Master’s of Business Administration (MBA) graduate programs spend months, perhaps years, studying project management yet instructional designers often have little experience in how to manage a project development schedule to insure that they are on schedule and on budget. Ironically, instructional designers are often offended when a subject matter expert is given the title “instructional designer.” They argue that this person’s area of expertise is the content, not instructional design. Similarly, an instructional designer is a subject matter expert on learning and the design of instruction. Why would anyone assume that a successful instructional designer will be a successful project manager if that person has no training in project management?

In other words, this is a very important topic for instructional designers as they will probably be required to perform some or many project management responsibilities. The goal of this paper is to reflect on our experiences as instructional designers and project managers and to provide practical suggestions for how to insure that successful instructional designers are also successful project managers.
Expert Opinions

There are three members of this panel plus a chair. Jackie Dobrovolny, Rod Sims, and Tim Spannaus are the panel members. Joe Lamos is the chair.

Jackie Dobrovolny

Jackie began her career in instructional design with no instructional design or project management experience or training. That was 25 years ago. Currently, she has a Ph.D. in instructional design, has taken several project management (MBA) courses and managed numerous projects. In 2001, she conducted an informal study of instructional designers and project managers at the annual conference of the International Society for Performance Improvement. In three separate round table discussions, she asked a total of 38 conference participants to sort 43 index cards, each of which contained a brief description of one knowledge or skill (see Table 1). The 43 cards were divided among participants at each round table and participants then sorted their cards into one of four stacks: instructional designer only, project manager only, both instructional designer and project manager, or neither instructional designer nor project manager. Each person at each of the three round tables received approximately four cards to sort. Once all 43 cards were sorted, the participants at each round table discussed and altered each of the four stacks of cards.

The results (see Table 1) indicated that of the 43 knowledge and skills, the participants at all three round tables labeled 22 of them in the same way. That is, they agreed that six knowledge and skills were unique to IDs, three were unique to project managers, and 13 were the responsibilities of both IDs and project managers.

453
managers to insure their input improves the product within the allocated time and budget

Table 1: Instructional Designer (ID) and/or Project Manager (PM) Knowledge and Skills

Interestingly, the three groups completely disagreed on two responsibilities. The three round table participants categorized “Manage revisions cycles...” as ID only, PM only, and both ID and PM. They categorized “Team building...” as PM only, both ID and PM, and neither ID nor PM. They also disagreed on the following responsibilities: knowledge of effective motivation and/or reward strategies, knowledge of individual differences research and diversity literature, knowledge of various instructional design models and theories, and use of return on investment formulas and strategies to evaluate a project. This data suggest that there is significant disagreement on the responsibilities of a project manager. Instructional designers need to discuss this disagreement and at least clarify the overlap.

Rod Sims

Rod has been an instructional designer for several different organizations and wrote Authorware With Style. Recently, he took a position at Deakin University as manager of technology-based instruction. His team develops both e-learning courses and degree programs and his responsibilities include hiring and evaluation, staff training, budgeting, and internal marketing. He rarely exercises his instructional design skills and he finds that he misses that activity. While his management position is challenging and fulfilling, he longs to exercise his creativity designing instruction.

Perhaps it is possible to be effective at and enjoy both project management and instructional design. The creativity that fuels a good instructional designer is, however, neglected in project management and thus, we need to consider the possibility that good (creative) instructional designers should only be promoted to project manager when their creativity needs a rest.

Tim Spannaus

Tim is President of ibstpi (International Board of Standards for Training, Performance and Instruction) and contributing author of Instructional Design Competencies: The Standards (ERIC/IT, 2001). The Competency book resulted from a study over several years of the required competencies of instructional designers. By broad agreement among the respondents to the validation study, management skills were rated as highly critical to the success of a designer. Most of the management skills were regarded as advanced skills, in recognition that novice designers were likely to work as members rather than as leaders of teams.

In a separate, not yet published study of training manager competencies, it has been found that managers need to have some instructional design competencies. This finding confirms the idea that in an ideal world, the competencies of training managers and instructional designers overlap.

Tim is Senior Lecturer and Research Fellow at Wayne State University (USA) and Chairman and Chief Learning Architect of The Emdicium Group, Inc.

Joe Lamos

Joe has been in the field of instructional design and development for 32 years. For more than 20 years he has managed instructional design projects and teams of instructional designers and developers. Joe holds a
Ph.D. in Educational and Psychological Studies from the University of Colorado. He is currently Acting Director of the Cooperative Program for Operational Meteorology, Education and Training (COMET), a division of the University Corporation for Atmospheric Research (UCAR) in Boulder, Colorado.

Most worthy education or training efforts today require a team to accomplish. If the project is to provide an instructional solution to a performance problem, because that is what is needed, then project leadership should preferably come from someone who can articulate a vision of the learning environment, learning tools or materials that need to be created. This doesn't necessarily need to be someone trained as an instructional designer but it should be if the ID discipline is to continue to be relevant relative to the content disciplines (which traditional perceptions hold as the core need in doing training or education). An important distinction that needs to be made is that between project leadership and project management. For practical reasons these two foci can exist in a single individual but that is not a necessity.

References

Introduction
A research and development project directed at e-learning has taken on the design and build of an educational object repository. As part of this undertaking, various tools for indexing, sharing, multipurposing, and repurposing learning objects are also under development. Advanced Learning Object Hub Application (Aloha) is one of these. It is a suite of tools used for the discovery, management, customization, and delivery of learning objects. For use by indexers, educators and learners, Aloha includes versatile and powerful indexing tools for different metadata standards, inter-repository searching and content and object packaging. These management tools include the ability to customize, or repurpose learning objects by educators and their students. The content packages of educational material are created in a standardized way that will allow them to be multipurposed between the desktop, the web, and CD-ROM using other existing software. Development is ongoing and contributions from other projects are being sought. What follows in an outline of some of Aloha’s features.

IMS, CanCore, DublinCore Metadata Indexing
The current primary function of Aloha is indexing educational objects. It is a Java-based client tool. The decision was based on the power and flexibility Java has demonstrating in interacting with the world wide web (Jones, 1997). Its flexible interface is friendly for amateur users and customizable for the professional indexer. It is easy to create, share and customize indexing templates and forms. It is able to automatically parse and fill in the metadata for over 200 file types. It makes marking up IMS or other forms of metadata much easier. Administration tools managing workflow issues with multiple indexers including the librarian, the educator, and the media developer are also available. This supports the idea of modularity where different users can index objects in context specific ways and share their metadata with other users and metadata schemas (Duval et al 2002).

Any valid xml schema can be brought into Aloha and users can begin to use the Aloha interface to help them build productive tools for indexing tasks. Learning Objects and metadata can be uploaded simultaneously with a touch of a button to an appropriate media server, handling the job of a FTP program.

Inter-repository Web Searching
A stand-alone application that serves as a client for the world-wide web, Aloha allows multiple resources to be searched. Like Apple’s Sherlock, its open architecture allows the addition of search-plugs to leading learning object repositories. It comes equipped with plug-ins for several existing learning object repositories. Using xml-rpc other repositories can be added with ease.

There are currently peer-to-peer options available to the user of ALOHA through the SPLASH peer-to-peer network being established by the POOL (what does this stand for and is there a web link) project. The peer-to-peer network will be like any other repository that you want to search, you need pick it as a search option. Aloha’s search capabilities are simple to use, easy to expand, and more effective than standard web
searches as they are based on well-defined standardized, metadata. The current search engines on the Internet are powerful but they are accessing an unmanaged resource which often returns irrelevant material (Pollock & Hockley 1997)

The best centralized learning object repositories will be vetted and restricted in their access, in so far as uploading of learning objects. The ability to set the access level of your uploaded object allows you to create trusted groups that can only view your objects if you give them permission. This will allow personal collections of learning objects to be shared amongst ad hoc communities of educators and learners. Desktop repositories can be batch uploaded to centralized repositories if desired.

Content Management and Multipurposing
Once a user has found a resource, whether it is downloaded or not, or if they have created a learning object themselves, Aloha's future features include content management and multipurposing functions. These features are important to enable users to download objects, manage courses, and deliver those objects in a revolutionary way. Aloha will allow users to create SCORM-based edulists and courses and organize these for personal use or sharing with educators or students (ADL 2002). Once arranged, Aloha will let users share their edulists, classes, and courses with students and other educators through the web, email, or uniquely through Aloha. The will also be able to publish their course packages with any software that will read these standardized packages. Learning objects can be visualized uniquely, customized to the users needs allowing content re-purposing.

Summary
This paper describes Aloha in brief detail. The presentation will demonstrate some of its features. One of the most important principles of Aloha is to open its architecture even further to allow a sustainable development environment and promote its usage among educators.

Flowcharts as a Basis for Procedural Training and Task Support

Arlington, MA 02474

Abstract

In the work reported here, we have set ourselves the goal of creating cost-effective high-quality automated on-line learning environments for procedural tasks. The result is an initial implementation of a system called the Flowchart Task Tutoring and Tracing Toolkit (FT4). The procedure language developed for FT4 is significantly richer than that used in most previous scenario-based procedural Intelligent Tutoring Systems (ITSs). On the other hand, it is less expressive than the plan languages used in previous model-based procedural ITSs. Our aim is to share some of the authorability advantages of scenario-based systems, while achieving much of the generative power of model-based systems. To date, we have designed and implemented the language with an ASCII encoding, built and packaged an interpreter that can interact with external simulations and prototyped a first application, and begun to explore the interaction of the interpreter with a student modeling component.

1. Goals and Definitions

In the work reported here, we have set ourselves the goal of creating cost-effective high-quality automated on-line learning environments for procedural tasks. The result is an initial implementation of a system called the Flowchart Task Tutoring and Tracing Toolkit (FT4). We start by elaborating on what, exactly, our goal description is intended to mean.

By procedural tasks, we mean any process to be carried out (or supervised) by a person, where that process calls for a reasonably well-specified (though by no means rigidly fixed) sequence of operations. Examples might include:

- controlling complex technological systems (e.g. industrial plants, satellite clusters),
- dealing with narrow social or business interactions (e.g. staffing a help-desk or a check-out line),
- or even mastering the cognitive aspects of complex constellations of physical skills (e.g learning to perform cardiac life support techniques, or machine maintenance activities).

By high-quality learning environments, we mean settings that incorporate, and effectively interrelate adaptive instruction, practice, and coaching. In on-line environments, practice is typically provided by interaction with simulations. Automated instruction and coaching call for artificial intelligence (AI) components that typically go under the heading of intelligent tutoring systems (ITSs).

By cost-effective, we mean our goal is to lower the costs of fielding these systems. We believe that, at least for procedural tasks, raw technological capability is no longer the barrier to widespread adoption of effective advanced learning environments. We know how to build interesting and useful systems, but typically it takes too much time, expertise (and therefore money) to build, distribute, and support them. Such systems require a mix of domain, instructional, and computer-science expertise.

Thus, in summary, we are interested in building a particular class of simulation-based intelligent tutoring systems, and doing so in a way that makes these systems more affordable in both the short and long run. We believe this is the best way to make truly engaging and effective instruction available to the widest range of students. In addition, the architecture we propose extends neatly to provide on-line task support in those cases where the procedural task is naturally performed with computer-support.
2. Comparing Procedure-Oriented ITSs

There have been a number of systems developed to support intelligent tutoring on procedural tasks, taking both scenario-based and model-based approaches. Prior to the work described here, we at SHAI had developed a library module called the Task Tutor Toolkit (T3) (Ong and Noneman, 2000) that emphasized authorability of relatively simple scenarios. Likewise, Guralnik (1996) describes an authoring tool, called MOPed-II, that applies a content theory of task knowledge to enable the tutoring system to generate replies to common procedure-oriented questions. The RIDES system (Munro and Pizzini, 1995) and its successors are probably the best-developed systems extant for authoring graphical procedure-oriented training simulations (frequently, of devices) integrated with the intelligent tutor; it too takes primarily a scenario-based approach. In contrast, we could cite more ambitious and elaborate model-based (and dialog-oriented) systems such as the BE&E tutor (Core, Moore, and Zinn, 2000), or the sequence of systems (i.e. TOTS, STEVE, PAT, and PACO) described by Rickel, et. al, (2000).

These systems vary on several dimensions:
- Type of task environment simulation and/or degree of integration with a particular simulator;
- Complexity of procedures that can be specified/trained;
- Relationship between procedure specifications and “problems” or “scenarios”;
- Relationship between procedure specifications and student models;
- Attention to and support for authoring;
- Support for lessons/tasks other than procedure practice.

There are two major stances on the issue of how a procedural ITS package might relate to a simulation environment. Either the simulator is integrated into the ITS package as with RIDES, or the tutoring component is explicitly packaged as a module designed to be interfaced with a variety of external simulators as with T3 and the TOTS et. al. line of work. The first approach allows for a highly integrated system that can fully support all aspects of ITS development. The second approach makes more sense in domains where simulators are either already extant, or are likely to be more complicated than (or inappropriate for) the simulation and authoring tools in the integrated environment. Our current work on FT follows in the tradition of T3 in being separate from any particular simulator.

The issue of procedure complexity is currently the strongest point differentiating FT4 from prior work on procedure-oriented ITSs. Scenario-based ITSs such as RIDES and T3 adopt something like a simple tree representation for procedures, where internal tree nodes can represent either ordered sequences of children or unordered collections of children, and external leaf nodes represent primitive actions. T3 adds the capability of generalizing the parameters to primitive actions to ranges or sets rather than fixed values. FT4 for its part, allows a much more general procedure representation that includes not only ordered and unordered sets of steps, but also (1) named sub-procedures with parameters and local variables to supplement global state; (2) conditional branches, and thus potentially loops; (3) exception conditions; (4) alternative steps; and (5) optional steps. Section 3 presents the full procedure language in detail. While a significant generalization over other scenario-based tutors, FT4 procedures remains less expressive than the plan language used in most model-based tutors.

Procedure specifications in scenario-based systems are created as part of defining a particular lesson or problem. Each procedure specification essentially represents a particular scenario or problem that may be asked to work through. Supported by the more complex procedure language, FT4 takes the stance that a procedure specification may represent a particular scenario, or a large chunk of the curriculum (from which many different scenarios might be generated). Thus FT4 aims to bridge the gap between scenario-based and model-based procedural ITSs with a representation of intermediate complexity. The basic idea is that mastery of the full procedure requires demonstrated ability to execute all the right steps at the right time (essentially, to run the student through a set of scenarios that exhaustively cover all the branches and transitions in the procedure).

The current FT4 prototype does not yet fully implement this approach, but many of the underlying facilities are in place. In particular the system maintains student models that reflect the transition structure of the encoded procedures. The system scores a student on three dimensions: (1) how often they
correctly execute an action indicating they followed a valid transition in the procedure graph; (2) how often they fail to execute an action that is required by a forced transition in the procedure graph; (3) how often they incorrectly execute an action that represents an incorrect transition out of a conditional test. This strongly procedure-centered view of student model is significantly different from the learning objectives or principles centered view taken by other systems.

One of the nice features of a simpler procedure language is that it is more easily authorable by subject matter experts who are not computer science experts. Both RIDES and T³ aim to ease scenario authoring by supporting a scripting by demonstration capability (in both cases complemented by a post-editing phase allowing somewhat different degrees of procedure generalization, as described earlier). Currently FT⁴ offers no authoring support for its procedures, and this is a recognized gap in its aim to address the problem of ITS cost. However, we have plans to integrate FT⁴ both with the enacted sequence recording capabilities of T³ and with a graphical flowchart editor that enables much more significant generalization of enacted sequences. We note that the design of the FT⁴ procedure language was shaped by the expectation that a simple flowchart interface would be created; it relies on a primitive branch and link representation rather than more modern structured programming language constructs.

We note also, that flowcharts have been exploited in instructional and task aiding system in other contexts and for other purposes. For instance, FAST (Thompson, Ockerman, Najjar, & Rogers, 1997) is a wearable electronic performance support system intended to offer factory personnel just-in-time advise. One form of advice available is explicit flowchart representations of tasks to be accomplished presented to workers in response to questions such as “How do I do this?” Slightly further afield, Puerta (1993) describes how flowcharts can be used to support authoring of task-specific support tools. In his examples, physicians design protocol flowcharts, that then serve to help structure system behavior and interfaces.

3. The FT⁴ Procedure Flowchart Language

In this section we provide a detailed specification of the FT⁴ procedure flowchart language. Each flowchart represents a named procedure. There can be any number of procedures defined for an ITS, and steps in one procedure can invoke other procedures (including themselves recursively, either directly or indirectly).

Each procedure contains a set of steps, linked to one another through “next” pointers. Basic steps have just a single “next” pointer, while test steps can have two (or more) “nexts”. Steps (or branches out of test steps) without an explicitly defined “next” are taken to constitute the end of a path. A path may be a route through a whole procedure, or may be the end of one chain in a parallel-step (which will be discussed at greater length below).

In addition, a procedure may specify exception conditions. When an exception condition becomes true, all other steps become unavailable, and control jumps to the step specified by the exception handler. When the chain of steps beginning with this initial step of the exception handler is completed, control can either return to the point where the exception occurred (indicated by a special-purpose return-step), or it can jump to a statically specified point in the flowchart.

Ignoring exception return-steps, procedure start-steps and other such special-purpose step types, there are five main kinds of steps:

- **Primitive-Step**: A primitive-step corresponds to a real-world action. In order to move past such a step, some action must be taken.

- **If-Step**: An if-step is a kind of test-step that is a simple if-then-else two-way branch. If the test expression evaluates to true, then the first path should be taken, otherwise, the second path should be taken. Thus an if-step has two next steps, but only one or the other is ever available.

- **Cond-Step**: A cond-step is a more flexible kind of test-step than the if-step; it resembles the “cond” form of the Lisp or Scheme programming languages in that it can have any number of distinct tests, each of which controls a possible branch. The tests are evaluated in order, and the

---

1 An interesting feature of T³ is that, contrary to the approach in RIDES, it does not require tight integration with its own simulator system to achieve this scenario scripting by demonstration capability.
branch paired with the first test that evaluates to true is considered active. A cond-step has as many next steps as it has tests, but again, only one is ever available.

- **Procedure-Step**: A procedure-step represents an invocation of a nested procedure. When a procedure-step is reached, control jumps to the nested procedure. When that nested procedure completes, control resumes with the procedure-step’s designated next step.

- **Parallel-Step**: A parallel step consists of several possible chains of execution, some of which may be specially designated as *optional*. A parallel step specifies a minimum and a maximum number of the main (non-optional) chains that must be completed. A chain is completed by reaching a step in the chain that has no next step. The user may jump back and forth between steps in different chains, and can start new main chains, up to the designated maximum number. Once the minimum number of main chains are completed, and so long as no other chains in the parallel-step are in progress, the parallel-step’s own next step may be executed.

Parallel-steps are the most complicated type of step. They were designed to support unordered or parallel actions (i.e. a set of N main chains, with the minimum and maximum chain counts both set to N), alternative actions (i.e. a set of N main chains, with the minimum and maximum both set to 1), and optional actions (i.e. allowance for a set of optional chains). But the minimum/maximum capability also allows for the somewhat odder possibility of unordered subsets of the main chains (i.e. a set of N main chains, with the minimum set to J and the maximum set to K, where 1 <= J <= K <= N).

The FT4 procedure flowchart language can be cast in several different forms. Currently, we have defined an ASCII file format (based on Lisp-style S-expressions), and an in-memory Java data structure format (suitable for tracing through procedures and determining, at each point, what are the current allowable set of actions a user might take). As suggested by the title of the system, the language was also designed to have a direct mapping to graphical flowcharts. Such a graphical language has been designed, but not yet implemented. Figure 1 shows a sample procedure for making cappuccino, primarily intended to illustrate the majority of features of the language (and to highlight possible problems as well).

![Figure 1. A Flowchart View of the Sample “Cappuccino” Procedure.](image-url)
The outermost heavy-lined box in Figure 1 represents the entire “Cappuccino” procedure. It is divided into two parts: (1) the mainstream procedure flow (the larger area with the darker background), and (2) the exception conditions (the smaller area to the right with a lighter background). The main procedure is composed of three major sets of steps, where each set is grouped into a complex parallel-step. The parallel-steps are the boxes with medium-weight lines, and with Min/Max counts shown attached. Again, the parallel-steps are potentially broken up into two parts: (1) the set of main chains (shown with a darker background), and (2) the optional chains (present only in the middle parallel-step, and shown with a lighter background). The thin-lined rectangles represent primitive-steps. The thin-lined rounded rectangle “Grind Beans” represents a procedure-step (the invocation of some other named procedure, whose detailed structure is not shown in this figure). The thin-lined diamond “Enough Foam?” represents an if-step that has the effect of creating a loop.

From the start state of this procedure, the only reachable step is the first parallel-step that packages the two “Select Cup” primitive-steps as the starting (and ending) points of two alternate chains. These are alternate chains because the min and max constraints are both set to 1. That means that as soon as one of the “Select Cup” steps is executed, a first chain has been started, and since the maximum number of allowed chains is 1, no other chain can be executed. Whichever “Select Cup” primitive-step is executed also completes the first parallel-step.

From that point, it is legal to start any of the three chains in the second parallel step. The chain consisting solely of “Pour Syrup” is an optional chain, and so its execution does not count towards the min/max counts of the parallel-step. With min and max both set to 2, the two main chains must both be executed to fully satisfy the parallel-step. The two main chains are a bit more complex than those in the first parallel-step. The chain that starts with “Grind Beans” is a straight sequence, except that the “Grind Beans” step is shown as a procedure-step—a reference to another procedure—and therefore could require some arbitrarily complicated set of actions before it is possible to advance to the “Load Grounds” step. In the second chain, we illustrate the use of an if-step, and the creation of a loop; the point here is simply to show that tests of environmental conditions are allowed and can be used to determine what steps ought to be performed next. Finally, as an aside, we note that the chains of this parallel-step adhere to the structural rule that each chain is self-contained: there can be no crossing over from the steps of one chain to those of another.

The third parallel-step is similar to the first, but since its min and max are both 2, it amounts to an unordered “and” rather than an “or”—it is necessary to both serve the cappuccino and wash up to complete the parallel-step, and thereby to complete the entire “Cappuccino” procedure.

The only aspect of the procedure we have not yet discussed is the exception condition set to watch for attempts to steam milk when the pitcher is empty. Structurally, the interesting point is the return-step at the end of the exception-handler; this should cause control to return to “Steam Milk” step (which is the only place the exception could have been noticed). Of course an exception that can occur in only one place might be defined as an explicit test and branch at the point in question. Alternately, this exception might better be defined in the scope of the second parallel-step rather than in the scope of the procedure; however, our current syntax does not allow such distinctions in exception scope.

As noted earlier, this procedure language is less expressive than a plan-oriented language; this leads to procedures that are less flexible than they logically could be. For instance, there is no real reason to force the cup selection to be performed before starting in on preparing the components of the drink. Logically, the cup only needs to be selected before the first pour or ladle step (to ensure there is something to pour our ladle into). On the other hand, in procedural training applications, it is quite common for the “by the book” way to accomplish a task to be defined with limited flexibility (compared to all the possible sequences that might accomplish the goal in question). At least for the applications we have considered, we are not very concerned that the FT procedure language is too restrictive.

4. The SatCon Project

The work reported here was carried out in the context of a project called SatCon (for Satellite Control). The point of this project has been to demonstrate how AI technologies can be applied to build a system for US Air Force satellite controllers that provides both intelligent simulation-based training and
job task-support during actual operations. The project ran for six months, resulting in a first prototype that links the current FT4 with a simulator and a GUI through an agent community. We expect to start development of a more complete operational system in the summer of 2002, as part of a two-year follow-on project. Section 5 on future work lays out some of our goals for the ongoing effort.

Given the dual application requirement, the multiplicity of potentially relevant legacy systems, and the expected overall system complexity, an agent architecture was early identified as particularly appropriate. Given the nature of the satellite control task—complex and somewhat variable, with a wide range of contingencies, and with tremendously valuable resources at stake—operators in current (and projected) practice are largely restricted to acting within the bounds of pre-specified scripts or procedures. Those procedures are far too complex to be expressible in the T3 task language, thus our invention of the significantly more expressive FT4 language.

To date, we have (1) designed the FT4 procedure language (including internal data structures and external representations in both ASCII and graphical form), (2) built a parser to transform ASCII specifications into data structures, and implemented a tracing algorithm that tracks allowable next actions, (3) designed a complementary student modeling formalism, and mechanisms to use such models to drive selection and/or generation of training scenarios; (4) implemented student model creation and update during the procedure tracing process, (5) packaged the existing FT components so as to separate the training and task-support capabilities from any simulation or operational environment, and (6) constructed a first demonstration application by embedding FT4 in a distributed agent environment.

5. Future Work

Future work will focus on authorability. This will include porting the existing T3 capability for creating straight-line procedure specifications, and combining it with the interactive flowchart editor. In addition, we will complete implementation of the mechanism for automatically generating individual scenarios based on general procedure specifications combined with student models. With these additions, we expect to fulfill our goal of cost-effective high-quality automated on-line learning environment for procedural tasks.

6. References

Distance education has been described as a disruptive technology—an innovation that, while initially posing no threat to established institutions, over time challenges conventional practices and contributes to new ways of thinking (Archer, Garrison, & Anderson, 1999). I agree with this assessment. Distance education has already become more than an alternative form of delivery. It has shaken up the educational establishment, especially at higher education and corporate levels. Precisely because of this success, though, assessing potential at midstream can be a challenge. At times like these, instructional designers and providers can benefit enormously by stepping back, reviewing broad trends, and forecasting likely scenarios based on those trends. That is the purpose of this paper. A number of current trends are outlined and their likely impact on education considered. Then some brief pointers toward the future are presented.

Observers of distance education can point to a number of discernible trends affecting practice over the past several years. Trends do not determine the future, but they can provide a basis for present action and an understanding of possible futures. The trends discussed below are pulling in different directions—some fostering change, others reinforcing the status quo; some using technology in a controlling way, others using technology to empower individuals.

**Technologizing of School Systems**

School systems, particularly American K12 public schools, are facing pressures to modernize and “technologize” their processes by establishing more predictable outputs and methods (Tyack & Cuban, 1995). Although American public schools are the immediate point of discussion for this section, the principles extend to any schooling or educational system.

*Standardized competencies.* The standards movement has resulted in a common set of learning outcomes, presented in quasi-behavioral language, but at a fairly high level of generality to accommodate different teaching methods.

*System-side assessments and accountability.* Standardized assessments are part of an overall move to make schools more accountable to the public or to the government. Test scores are thus indicators of tax dollars and government resources being well-spent.
Incentivization of funding. Increasingly, operational funds are being tied to compliance with specific mandates and regulations. These mandates are made at levels beyond individual schools, intended to bring schools into line with desired teaching and assessment practices.

Regulated processes and methods. With increased emphasis on high-stakes testing, teachers are being asked to fit their teaching methods more closely to the larger system of goals and assessments. Often, methods are established and prescribed by schools, districts, and even states, leaving less room for professional judgment and variations in teaching style.

Alignment of outcomes, assessments, and methods. In a well-coordinated schooling system, an alignment exists between processes and outputs—in particular, between standardized outcomes, assessment measures, and acceptable teaching methods.

De-professionalizing the teacher's role. Tighter alignment of processes and outputs has a definite impact on the teacher's role. As suggested above, the teacher often assumes a "technician's" role of implementing prescribed rules, as opposed to a professional's role of exercising judgment.

Learner- and User-Centered Philosophies

At the same time schools are moving toward efficiency and control, the mood among many educators is definitely learner-centered. The constructivist movement in education stresses individual and collaborative construction of meaning. While many teachers wish they could teach in more learner-centered ways, the system can make it difficult. Teachers and trainers thus face a certain tension between efficiency and control on the one hand, and learner-centered flexibility on the other.

Convenient, anytime/anywhere access. Instead of students going to class, learning is coming to the student—in the workplace or at home. Just-in-time, just-in-place learning resources are increasingly available to learners in their normal living settings.

Constructivism. Constructivist teaching strategies give students complex and engaging projects and tasks to perform, with scaffolding and support from colleagues or a teacher/facilitator. Learning happens via meaningful experiences and direct encounters. Examples include guided inquiry activities such as Webquests, or problem-based learning cases.

Field-based and informal learning. Informal learning happens by virtue of participation in some other valued activity, e.g., work or play. Field-based learning refers to semi-structured activities such as internships, practicum experiences, expeditions and trips, etc.

High-touch connectivity. Many technology innovators maintain a dual focus in their dissemination efforts—providing advanced information tools coupled with high levels of personal support and connectivity among individuals (Naisbitt, 1982; Spitzer, 2001). The commitment to both high-tech and high-touch suggests a need to make tools people-centered rather than the reverse (Norman, 1993).

How does distance education fit within these conflicting forces of standardization versus learner-centered values? Ironically, distance education can be seen to support both movements. A well-conceived distance education program can fit squarely within a strictly controlled standards-based curriculum. At the same time, some aspects of the distance learning experience are completely learner-centered, especially the access and convenience afforded students.

Moves to Streamline and Automate Instructional Design

In this section several trends are outlined that relate to making instructional-design processes more efficient and effective through a process of streamlining or automation of tools and processes.

Standardized taxonomies for learning outcomes and instructional strategies. A basic precept of instructional design is known as the "conditions-of-learning" assumption (Ragan & Smith, 1996). Before producing instruction, you determine what you need to teach, as well as your audience and situation. Then and only then can good
instructional strategies be determined. According to this view, rules connecting goals with instructional strategies become essential to the systematic practice of instructional design.

Data-driven generation of rule-based instruction. An automated version of this line of thinking seeks to make instructional development largely a data-driven activity. Automated instructional design is an ambitious concept: Just plug in data concerning learning outcomes, learners, and situation, and the rule system spits out—not only a set of recommended strategies—but draft instructional materials. While research on automating instruction has continued over two decades, the agenda is still in its infancy, and may prove increasingly viable in coming years.

More flexible, adaptable authoring tools. Powerful authoring tools break from linear processes and allow late and iterative changes in design, more in keeping with natural design thinking and envisioning. Examples include 3-D modeling programs that allow for various uses once the model has been created; or authoring tools that allow prototyping and creation of dummy interfaces, to test out concepts at early stages before investing in full-design development.

More modular, re-usable design. The learning-objects movement is about reusing content to make efficiency gains in the instructional development process. Because digital content is “non-rival” in nature (i.e., copies of equal quality can easily be made from originals), reusability for various purposes, media, and occasions become an inviting possibility (Wiley, 2002).

The Digital Shift: Advances in Information Technologies

After their initial emancipating impact, new technologies eventually come to constrain our thinking and actions, especially after heavy investment in their use. Advances in information technologies over the last twenty years are so profound that they are affecting every area of our professional lives. I term this condition the “digital shift” because, as we convert our thinking, knowledge, and communication to digital and informational form, a whole new set of possibilities opens up (Brown, 2000; Brown & Duguid, 1996).

Digitized information is traceable and archivable. Exchanges and interactions are more easily captured, at least on a digital level. Digital databases are searchable to a degree that we can often retrieve needed resources when solving problems in real time. Because of their non-rival nature, digital resources are replicable in that they can be copied and distributed an infinite number of times at zero or extremely low cost. Using webs to link via hypertext interconnecting information has become commonplace in the problem-solving practices of information workers. Accompanying digital information is a stronger suite of tools: online communication tools will increasingly allow higher resolution, more modalities, more choice, and more fidelity to everyday encounters. These, along with more powerful representation tools, are leading to virtual worlds that allow for increasingly rich experience and interaction.

Global Marketplace

In recent years, economies worldwide have moved toward greater linkages and interdependencies. This move is called the global economy or the global marketplace (see also Collis & Gommer, 2001a and Collis & Gommer, 2001b for a helpful analysis on this general issue).

Economies of scale. By virtue of the Web and the shift to online learning, markets for learning resources have shifted from local to global. Thus a school in Australia may offer a course that attracts students from all over the world. A portal or website may compete against an office of student services within a community college. These shifts in markets and audiences create new economies of scale—allowing larger investment and larger outreach—but they can also threaten locally developed providers.

Globally distributed labor pool. A company based out of India may hire an experienced PhD at $3/hour to facilitate a graduate-level computer science course. This, in turn, may force a competitive response by a local school or learning-resource provider. By simple virtue of the Web, salary scales and hiring practices for online resource providers are starting to become more globalized.

Disaggregation of products and services. It can be hard to put a price tag on residential school experiences. What is a Harvard MBA worth, and where does the value lie? Many graduates would place great value on non-traditional outcomes, e.g., the network of friends and contacts; the exposure to a company’s work practices via an
internship; the rite-of-passage and developmental roles of schooling; the opportunity to take personal risks and test oneself. Online learning providers will need to somehow differentiate the valued outcomes of a schooling experience.

Commoditization of instruction. As suggested earlier, instruction can be seen either as a mass-produced product or as a unique experience. Because online learning resources require more up-front development than typical classroom experiences, and because online instruction is still seen as an entrepreneurial enterprise, there is a tendency to see online instruction as a commodity. Once investment has been made in the product, providers often want to distribute that product as far as the market will allow. This could also be called a shift from a craft to an industrial model of production and delivery. A view of instruction as commodity, of course, is compatible with viewing education in input-output terms.

Mixing of commerce and education. Many enthusiasts are disheartened at the commercialization of the Web, but it was a predictable effect coincident with increasing choice and individual control. A similar tendency is seen in schools as greater choices and perspectives are accommodated through charter and private schools. Commercial investment can provide the needed stimulus to innovation and development, but it can also reduce innovation and variation, especially small-niche perspectives at the fringes. Commercial appropriation of learning can result in some confusion through blurring of boundaries between consumption and education, between entertainment and learning. In an open market, where satisfaction of desire plays a critical role, learning outcomes may suffer from neglect.

Radical Forces Inspired by Global Connectivity

Web as democratizing, emancipating, empowering force. Early literature about the Internet was infused with optimism and idealism about universal sharing and access. The Web indeed can be an empowering force that gives information access to users who are physically remote from resources (Ryder, 1995). At the same time, the Web, like so many other tools, reflects our own values and ideas. A divide still exists between the privileged and the disenfranchised, but the rules have changed somewhat. Principal barriers now include lack of access and lack of cultural or personal fit with the technology. Age can even be a barrier to empowerment, with younger people tending to have more time and familiarity with technology than older generations.

Open source. The commercial model of technology advancement, exemplified in the software industry by Microsoft, is being challenged right now by the open source movement. Linux, an operating system whose source code is open for the world to see and costs nothing to download and use, has become a major movement in the software development world. Open-source advocates are trying to create a world where software is freely available and a living is made through continuing relationships of service and support. Open-source ideas may be applied to online learning and education: Challenge commercial ownership by making resources freely available, for example, on the Web. If communities of practice can be organized around openly available tools and resources, then the system can become self-sustaining and reinforcing to participants (Schrage, 2000).

Self-publishing and knowledge sharing. Self-publishing is to knowledge management as open source is to Microsoft—an alternative to a hierarchically controlled system. Instead of fixed search categories and a company-designed form, end users themselves can publish solutions and locally valued resources. The Web epitomizes this growing trend, to the occasional chagrin of copyright owners and librarians (Ryder & Wilson, 1997).

Peer-to-peer networking. The Napster phenomenon taught us that downloading from central servers is not the only way to perpetuate an online enterprise. Peer-to-peer networking refers to individual users sharing resources by opening up their hard drives to each other. The core concept is even more radical than Napster's, because once out of the bag and in the hands of end users, true peer-to-peer usage cannot be controlled. In this way peer-to-peer networking constitutes a classic form of self-organizing system, using the technology to bypass every form of central control.

Self-organized learning- and performance-support groups. Peer-to-peer connectivity is the extreme end of self-organizing on the Web, but there are other forms. Interest groups, listservs, support groups of all kinds—Each of these is a self-organizing system that draws on distributed energy and participation for its survival. Slashdot.org is a primary example (Wiley & Edwards, 2002).
Threats to credentialing, degree-granting institutions. In the last decade, competency-based approaches are increasingly offered as an alternative to seat-time approaches for credentialing institutions, thanks largely to growth in online and self-directed learning. For-profit outreach institutions like the University of Phoenix, once ridiculed for giving credit for “life experience,” continue to gain market share against residential institutions. In spite of reliability problems, professional portfolios are increasingly used for competency demonstration and evaluation. Online learning, where seat time loses much of its meaning, continues to improve its services and learning outcomes, along with market share. These “disruptive technologies” and accompanying competency-based tools are truly disrupting the status quo.

Global education as an alternative to a national curriculum. Global education refers to a new philosophy of learning that seeks to create responsible citizens of the world. Transcending national interests, the global education curriculum takes broadly based positions on issues of non-violence and conflict resolution; sustainable growth policies; treatment of rich and poor; and protection of the global environment (McEneaney, Kolker, & Ustinova, 1998).

Reflections

How do these various trends add up? I hope the reader engages in some reflection and conversation about that question. What follows is my best effort at generalizing upon the trends. Rather than paint a specific scenario, I highlight a few principles suggesting how the trends may combine.

The trends keep marching on. Each of the trends listed above will continue to play a role in future developments of education and training, where distance technologies will play an expanding role. The trends may compete with one another, or sometimes cancel each other out. But they all represent significant aspects of the problem space within which distance education of the future will take shape.

Open systems trump closed ones. This is my way of saying, learners and communities will find a way to appropriate emerging tools and technologies, rather than the reverse. I have a bias that says that open systems (self-directed learners, self-organizing groups of learners and workers) constitute the most vital and thriving unit for understanding human actions and choices (cf. Hill, 1999). Process efficiencies and mass-produced tutorials can be appropriated and put into service by these learners and groups, and that is good. Where a group can appropriate a tool or technology and use it to learn from, let it do so. Where the technology breaks down, the group will adapt and make do. This is not a Utopian faith in the goodness of people; rather, it is an acknowledgement of the power and priority of groups that identify us and guide our behavior. Schools as collectivized learning institutions will not go away. Teachers or guides, responsible for the growth of novices, will not go away. Collective learning in real time will not go away. These practices are in place, not because we lack alternatives, but because we are social beings who invest considerable time and resources toward local interactions and support. I am confident that the same groups—schools, classrooms, families, workgroups, professional organizations—will find ways for distance-education resources to work in their service.

Technologies are still reflections of us. Through technologies and new ideas, we are always in the process of re-inventing ourselves. Technologies serve as mirrors of our values and aspirations, as well as our weaknesses and intractable problems. This truth about technologies underscores the importance of subjecting our plans to continuing scrutiny. Whenever possible, we want our technologies to reflect our best selves and our highest ambitions.

Technology and ideas will continue to co-evolve together. Historians of technology tell us that a technology, often based on the best thinking available, in turn stimulates new thinking and new possibilities. This is certainly true of the Web and networked information systems. A huge spike of promising ideas, models, and R&D efforts has accompanied the new technology. When these new efforts are seen as artifacts themselves, we see how one technology prompts the development of another, and how the cycle repeats itself through new iterations of technology, design, theorizing, and practice. Thus we can be sure that, as technology continues its onward march, new models and ideas will surely follow—and in some cases, precede the technology itself. As John Dewey said more than seventy years ago:

Many are the conditions which must be fulfilled if the Great Society is to become a Great Community... The highest and most difficult kind of inquiry and a subtle, delicate, vivid and
responsive art of communication must take possession of the physical machinery of transmission and circulation and breathed life into it. When the machine age has thus perfected its machinery, it will be a means of life and not its despotic master. (Dewey, 1954/27)

Supporting and Hosting Web-Based Learning Systems in the University of Wisconsin System
(this document was created in MS Word 2000)

Charlene Douglas
Director, dot.edu
University of Wisconsin System
Milwaukee, WI

Economy of Scale

The University of Wisconsin System (UWS) consists of 27 individual campuses (two research institutions, eleven 4-year universities, thirteen 2-year colleges, and an extension) plus Learning Innovations (LI) (a UWS organization that focuses on total online programs). Several years ago UWS found itself inundated with requests from these individual campuses and LI for financial assistance for the following.
- Web-enhanced and web-based learning
- Enhancement of their respective libraries
- Expanded curricular redesign efforts

Since it was not possible for UWS to support such endeavors on each campus and since such funding would basically re-invent the wheel 28 different times, UWS decided to implement a Distributed Learning System Environment. The philosophical assumption behind this type of environment is that the 27 campuses of UWS plus LI could receive a much greater return on investment if they collectively take responsibility for infrastructure investments (with infrastructure being defined as a base that is universally accessible, potentially used by all and has value in its commonality).

The University of Wisconsin System has attempted to establish a well-defined set of support services for internet-based teaching and learning for its 27 campuses and LI. The objectives of these services are: 1) to provide all University of Wisconsin (UW) campuses with the opportunity to use distributed learning technologies to enhance teaching and learning, 2) to guarantee a learning and teaching system infrastructure (including software, hardware, and staffing) that enables on-campus and off-campus network-based courseware, and 3) to provide a longer term funding model that will ensure core distributed learning services for all faculty and teaching staff.

UWS's Distributed Learning System Environment includes such services as the following.
- Instructional Design, Course Development and Faculty Support
- Copyright Clearance Center
- Video Production and Digital Television
- Asynchronous Library Services
- Network Services
- Student Support Services
- Statewide Distance Education Communication, Coordination, Support, and Web Maintenance
- Web-Based Learning System (WBLS) Hosting, Help Desk, Training, and Support
It is the last service on which this presentation will focus. UWS sent out RFPs to all 27 campuses and LI to provide this service. The successful campuses were the University of Wisconsin - Eau Claire which focused on LearningSpace, the University of Wisconsin - Madison which focuses on WebCT, and the University of Wisconsin - Milwaukee (dot.edu) which focused on Web Course in a Box and Blackboard. Therefore, instead of providing this service at each UW campus and LI, the Web-Based Learning Systems provide this support from these three central locations for all UW campuses in a much more cost-effective fashion.

Web-Based Learning Systems (WBLS)

Services
For whichever of the products chosen, the following services are provided.
1. Hardware: server access, disk space as necessary
2. Software: for course development (license, vendor support, upgrades, renewals, separate instance); for course delivery to students
3. Staffing: professional development; instructional workshops in the use of the software; accessible and sustained support to institutions, educators, and students; instructional design consultation; 24x7 help desk (toll free number) for faculty and students; Network and System Administrators

Thus, WBLSs provided faculty and teaching academic staff throughout UWS a choice of four web-based learning tools for course presentation.

Faculty Benefits
The faculty using these tools report many benefits: versatile courseware, time for active learning, online courses that can mirror classwork, problem solving activities, and collaboration. These tools vary in ease of use and make it possible for faculty to create meaningful courses that range from the very basic to the highly interactive, from web-enhanced to distance education.

Student Benefits
Student benefits are numerous. Web-based and web-enhanced learning provides a consistent look and feel to course information and resources; provides anytime, anywhere, any pace instruction (most beneficial to non-traditional students); allows students to continue the conversation beyond the traditional classroom's constraints of time and space through collaborative tools such as discussion forums and virtual chats. Students now have the ability to begin the process of becoming lifelong learners.

dot.edu

dot.edu is an Application Service Provider for the State of Wisconsin and beyond. The impact of dot.edu has been tremendous: we have 6880 courses in some phase of development; 4500 faculty have been trained; and 131,000 students are enrolled in these courses. We are in both UW-System research institutions, 10 of the eleven 4-year UW-System universities, all thirteen 2-year UW-System colleges, UW-Extension, and Learning Innovations. We have 29 non UW-System partners who pay to use this service.
This involves 30 Dell servers; 4 larger Sun servers; a very large environment for the most recent web-authoring tool that we’ve added (Prometheus); a video server; a tremendous amount of travel, coordination, collaboration, strategic partnerships and, at present, a cost of approximately $1,000,000.

**dot.edu Partnership Model**

**Process**

The partners of dot.edu include all faculty, teaching academic staff, and administrators in the following categories:

- The UW System campuses
- Wisconsin public and private higher education institutions
- Wisconsin public and private schools and districts as well as education agencies in the state
- Non-educational institutions and those institutions outside the State of Wisconsin

Programs can be selected and uniquely organized to meet the needs of the particular partner. The Utility model is structured as a 3-stage implementation plan that eventually transfers responsibility for course development instruction from dot.edu to the partners.

- **Stage 1**: dot.edu provides direct instruction and support to the on-site trainers
- **Stage 2**: dot.edu provides direct instruction and support to first set of instructors, with support from on-site trainers
- **Stage 3**: On-site trainers provide all direct instruction and support to subsequent sets of instructors, with support from dot.edu.

The course development instructional program design and implementation timeline are determined by the needs of the institution. A written implementation plan is designed jointly by dot.edu and the respective institution. It is developed with the flexibility necessary to meet changing needs. The campus eventually sustains the course development instruction.

**Pricing**

Pricing is constantly being revisited but, in general, contains an annual fee of approximately $30,000 and a per course section fee of approximately $150. Firm quotes are given upon request and after review of services needed. The fee includes the hosting, 24 hours of training and/or instructional design consultation, the 24x7 Solution Center, unlimited users, unlimited courses, and unlimited disk space. Additional training can be obtained for $200/hour plus expenses.

dot.edu does provide an Incubator for Prometheus (for those customers who might need time to determine if online education is for them, for customers to try out the dot.edu services, and for customers to try out the Prometheus software). A per course fee is charged for this service (prices given upon request; typical charge would be $500/course section).

UWS currently subsidizes the UW-System 27 campuses and LI so that each campus does not have to budget for these services - therefore, these services are provided, sponsored, and funded centrally. Non-UWS customers pay the fees mentioned above.
New Developments

It was realized that the WBLS, WiscNet, Wisconsin Public Television, the Pyle Center, Learning Innovations and others were providing their services to all educational institutions in Wisconsin. In order to make it easier for these educational institutions (with regard to costs, contact information, services provided, and so forth), it was determined that a type of clearing house be established to act as the conduit for the various state Service Providers. Thus, ITS@Wisconsin was formed (Instructional Technology Services @Wisconsin), providing a single point of contact for educational institutions in the State of Wisconsin. In doing so, the old name of Web-Based Learning Systems (WBLS) was abandoned.

As time progressed, UW-Eau Claire ceased offering LearningSpace and Web Course in a Box was purchased by Blackboard. In addition, a new web-authoring tool (Prometheus) was added to the mixture in December of 2000. Thus, UW-Madison offers WebCT and dot.edu offers Blackboard and Prometheus.

dot.edu has formed strategic partnerships with Dell, Sun Microsystems, WiscNet, Blackboard and Prometheus. In addition, dot.edu has recently received the Sun Center of Excellence award. Together with Sun Microsystems, Dell and Prometheus, dot.edu intends to take the dot.edu concept nationally to show other states that education can take care of education and provide a seamless PK-16 education.

Goals and Mission

The goals of dot.edu are not stagnant but ever changing.
- We will be partnering with the Student Accessibility Center at UW-Milwaukee to accompany us on all our training sessions to educate all faculty and students with regard to accessibility issues
- We will be instrumental in the formation of standards through the Wisconsin Co-Lab
- Disseminate knowledge
- Leverage resources to provide an economy of scale
- Support web-enhanced, hybrid, and online education
- Provide appropriate high-quality web-based learning systems
- Remove barriers preventing interaction between the UWS, PK-12, and other appropriate members of Wisconsin’s educational community

The mission of dot.edu is also constantly expanding but has always remained the same – provide educational communities with robust and up-to-date e-learning system infrastructure including technology, training, support, and instructional design and to effectively apply these resources to enhance education. dot.edu hopes to be able to provide a seamless e-learning experience to PK-16 and beyond.
What We Have Learned and Reasons We've Succeeded

Lessons Learned

Much has been learned in the process of developing dot.edu. Since nothing like this existed, we are constantly "making it up" as we go along. Continual refinement of policies and procedures, pricing structures, service agreements, and services offered takes place. Some of the specific lessons we've learned follow.

1. Identity issues - each of these Service Providers exist on a specific central UW campus but each is funded and sponsored by the University of Wisconsin System
2. Customer support - this is a very intense and expensive aspect of the dot.edu, much more than anticipated at the beginning
3. Dealing with unknowns on each campus - this comes into play when the training takes place on our partners' respective campuses
4. New products - since this is such a changing, volatile field at present, new products are continually being analyzed and tested
5. Legalities - copyright and intellectual property issues
6. Instructional design - it is quite a challenge to provide instructional design and pedagogical consultation through a distributed system
7. Measuring capacity and demand - regarding disk space, number and types of servers, personnel needed
8. Students - staffing has to be supplemented by student workers
9. External funding - it is imperative that partnerships are developed and external funding is sought
10. Administrative systems - it is becoming more and more apparent that it is necessary that these web-authoring tools integrate with individual campus Administrative back-office systems

Why We've Been A Success
dot.edu has been a tremendous success because of a few very simple reasons.
- Customer service - fast, friendly, and thorough
- A great product which is continually being improved and enhanced
- A buy-in by central administration, campus administration, and faculty
- Having as an end product of all of this - true collaboration and teamwork throughout the State of Wisconsin and beyond
- A willingness to go that extra mile
- An adherence to the mission of the dot.edu and ITS@Wisconsin
- A willingness to take the risk and go where no one has gone before
- dot.edu is Education Serving Education

Conclusion

Several years ago the UW-System had the foresight to see that a problem existed and they designed a solution. They then had the tenacity to actually try their solution. Its success has exceeded everyone's greatest expectations. Through dot.edu, the rest of ITS@Wisconsin and the entire Distributed Learning System Environment, the UWS faculty and campuses can now take education in the State of Wisconsin to that next level.
Agent Technologies in the Electronic Classroom: Some Pedagogical Issues

Carolyn Dowling
Australian Catholic University
Australia
c.dowling@patrick.acu.edu.au

Abstract: The use of intelligent software agents within computer mediated learning environments has become an important focus of research and development in both AI and educational contexts. Some of the roles envisaged and implemented for these electronic entities involve direct interactions with students, participating in the 'social' dimension of the classroom that is of such importance in contemporary pedagogical theory. Others contribute to the many background tasks that support the teaching/learning process. Each type of activity raises its own special challenges in relation to the capabilities of the software and to our understandings of teaching and learning. Through discussion of both theoretical perspectives and practical examples, this paper explores a selection of these issues.

Introduction

One of the fastest growing applications of AI research is the implementation of computer programs commonly referred to as 'agents'. Among the features distinguishing this type of software from more traditional programs are a high degree of autonomy in decision making and action, the ability to 'learn' from experience and to adapt their behaviour accordingly, and often a highly personified interface. Many are specifically designed to process complex information, make decisions and initiate actions in 'mission critical' areas of human endeavour including health, scientific research, business, defence and increasingly in education. While in some cases we are aware of our interactions with these electronic entities, in many contexts their activity takes place 'behind the scenes', at a level not apparent to the user. Agent roles currently implemented in educational projects around the world include record keepers, information seekers, testers, facilitators of collaboration, tutors or instructors, fellow learners, and tutees.

While the usefulness of this type of software in many contexts is already well proven, a number of issues in relation to its uses in education are not yet fully resolved. The substitution of computer programs possessed of varying degrees of artificial intelligence and 'personality' for various aspects of human presence in the computer based classroom, raises some quite fundamental questions concerning the processes through which knowledge is socially constructed, and the qualities which are necessary to ensure successful participation in those processes. To what extent can socially interactive roles such as tutor and fellow learner be effectively and appropriately fulfilled by a computer program, however 'intelligent'? Where agents undertake less interactive tasks such as record keeping and testing, other issues arise including that of privacy and of students' control over their own learning.

Agents in the electronic classroom

Typical of the broad vision held by many researchers and educators for the implementation of agent technology in the online classroom is that promulgated by Johnson, who writes:

“Pedagogical agents are autonomous agents that support human learning, by interacting with students in the context of interactive learning environments. They extend and improve upon previous work on intelligent tutoring systems in a number of ways. They adapt their behaviour to the dynamic state of the learning environment, taking advantage of learning opportunities as
they arise. They can support collaborative learning as well as individualized learning, because multiple students and agents can interact in a shared environment. Given a suitably rich user interface, pedagogical agents are capable of a wide spectrum of instructionally effective interactions with students, including multimodal dialog. Animated pedagogical agents can promote student motivation and engagement, and engender affective as well as cognitive responses" (Johnson 1998, p. 13).

Arguably the most obvious choice of interactive role for an agent would be that of teacher. While one might reasonably fear a resurgence of the heavily instructionist model of 'the computer as tutor' prevalent in the early days of educational computing, there are indications that developers are attempting to base their agent-based manifestations on aspects of pedagogical theory more acceptable to current thinking.

As Solomos and Avouris (1999) write, for instance:

"The user mental model of the system should be based on the metaphor of the ‘invited professor’ rather than the ‘knowing everything own tutor’. … Our first findings confirm the observation that today’s users, accustomed to hypertext-like interaction, are more likely to accept this collaborative teaching metaphor, according to which their tutoring system is viewed as an intelligent hypertext browser, offering links to other tutoring systems with the right content and at the right time" (Solomos & Avouris 1999, p. 259).

The image of the teacher as a facilitator of learning rather than as the ‘sage on the stage’ is also reflected in such statements as: “Each student working on the project will have an agent, operating in the background, watching progress, measuring it against the plan, and taking remedial action when necessary” (Whatley et al 1999, p. 362).

The substitution of agents for one or more of a student’s classmates or fellow learners is an interesting concept being explored by a number of developers. Successful implication of this idea would add considerable appeal to online learning environments. Currently, while electronic interactions between students can be encouraged and facilitated up to a point, the quality and timing are far less subject to the control of the ‘teacher’ than is the case in a face to face situation. The presence of ‘classmate agents’ would not only enhance the general social ambience of the online classroom, but could enable more constructive interactivity to take place at pedagogically appropriate times.

Since the 1980s Chan (Chan 1996, 1998) and colleagues have been working on a range of models of socially interactive agents for learning environments, perhaps the best known being the ‘learning companion’ – a software entity having limited knowledge of the domain in question, conceptualised as a fellow learner with whom the student may collaborate and even disagree. As in real life, some of these learning companions may be better informed than the student in the relevant domain of knowledge, while others may know less. Perhaps not surprisingly, in learning environments for younger students, animals are a popular choice of persona for such agents, as in this example of a networked learning environment for Taiwanese high school students, as described by Chan:

“The Dalmation is having the same performance as the student. … Another animal companion is Dragon, like one of those animal companions in Mulan, a Disney cartoon of this summer. This dragon will “learn” (mainly rote learning) from the student and also from other students on the Net and so may know more than the student. At certain point it’ll stop learning and come back to teach the student. In a way, Dragon is protecting the student." (Chan 1998)

An interesting development of this concept is suggested by Sheremetov and Nunez (1999, p. 310), who describe the function of a ‘monitor agent’ as being to modify the role, behaviour or expertise of learning companions. A learning companion’s personality could, for examples, be changed from that of strong group leader to a weaker companion or even a passive observer, depending on the monitor agent’s interpretation of the degree of guidance required by the learner.

A third socially interactive role that may be enacted by an agent is that of ‘tutee’. We are all familiar with the common wisdom that we learn best through teaching others. This principle was invoked in the early days of educational computing through Logo, where ‘teaching the turtle’ was the chosen metaphor for the activity of programming. More recently, a number of researchers have explored the translation of this concept into electronic learning contexts where agents exist to be ‘taught’ by the student user, as in the example from Chan quoted above. A further example is described by Ju (1998) who writes of a computer based peer tutoring system employing two categories of agent – an ‘expert’, and a ‘learner’:
\"... students become active learners who are guided to learn by teaching a computer. After the students watch how the computer expert solves a set of linear equations \[the program\] helps the human student act as a teacher in order to learn more about the subject matter. At this time, the computer plays the role of a student \"\n(Ju 1998, p. 559)

In addition to these highly visible and interactive \"social\" roles, there is considerable scope for agents to undertake a range of support activities including monitoring the activities and responses of students, administering tests, recording results and seeking information on behalf of students or teachers. The latter task is, of course, familiar to us in relation to the operation of standard Internet search engines.

Issues for consideration

Each of these implementations of agent technologies raises issues that demand consideration. While some are basically pedagogical, others straddle the boundaries between pedagogy and other areas, such as ethics. While some relate to whether or not the achievement of certain ends is a practical possibility, others go further and question whether what is possible is necessarily desirable.

A key element in the implementation of socially interactive agents is a high degree of personification or \"character\". It is well accepted that an element of personification of program interfaces is inevitable. As Shirk puts it:

\"Although there is some dispute among software critics concerning the advisability of having \"personalities\" in computer programs, their presence seems unavoidable. Any time there is communication between a computer and a human, the information presented by the computer has a certain style, diction, and tone of voice which impact upon the human\'s attitude and response toward the software\" (Shirk 1988, p. 320).

Deliberate personification is, however, more problematic. As Masterton notes: \"A common problem with AI programs that interact with humans is that they must present themselves in a way that reflects their ability. Where there is a conflict between the ability of the system and the users\' perception of that ability a breakdown occurs and users may either fail to exploit its full potential or become frustrated with its shortcomings\" (Masterton 1998, p. 215). He suggests the implementation of a style of pedagogical agent with a degree of anthropomorphism intended to convey qualities such as friendliness and usefulness, without the implication of possession of full human capabilities. He describes the development and role of such an entity, a VTA (Virtual Teaching Assistant), which is able to introduce topics and answer simple questions, the more complex types of exposition and interaction being left to the human teacher. In terms of a traditional scenario at university level, the VTA functions somewhat like a tutor or demonstrator as distinct from a lecturer. \"In this way faculty is left free of the guiding and assisting issues of the course and is able to concentrate on more complex questions and higher level issues generated during the course\" (Masterton 1998, p. 211). The \"learning companions\" of Chan mentioned above can be seen as further instances of this principle. Our expectations in regard the cognitive skills of animals may well be more appropriate to the capabilities of software agents than are our experiences of human-to-human interactions.

An agent\’s capacity to demonstrate some equivalent to the emotional responses of a human being, and to appropriately recognise and respond to the emotions of users is becoming recognised as an important element both in personification generally and in educational contexts in particular. As Frasson writes, \"Emotions play an important role in the learning process and new strategies have to take into account this human factor for improving knowledge acquisition. Intelligent agents can help in this process, adding emotional behavior to believability of their actions\" (Frasson 2000, p. 60).

Apart from the possibility that less fully personified agents might be more educationally effective, there are clear ethical issues attached to the presentation of these programs in a form which students are unable to distinguish from that of a human participant in the learning experience.

Another important characteristic of agent software is its capacity for autonomous or self-directed decision making and action in the pursuit of its goals. This raises the question of the extent to which a pedagogical agent should be furnished with pre-existing goals which could lead it to undertake actions without instruction from the learner, and even contrary to what the learner might perceive as his or her interests and wishes. Loeffler (1996) notes that the unpredictability resulting from significant autonomy might well result in
agents who are less 'helpful' to us than we might hope or indeed expect. As Minsky puts it, "There's the old paradox of having a very smart slave. If you keep the slave from learning too much, you are limiting its usefulness. But, if you help it to become smarter than you are, then you may not be able to trust it not to make better plans for itself than it does for you" (Minsky, 1994, p. 25). It is easy to slip from such considerations into the need for a contemporary version of Asimov's laws of robotics as conceived in fictional terms more than 30 years ago.

In educational contexts there is potential for some degree of conflict between the usefulness of an agent possessing a high degree of autonomy, and contemporary understandings of the importance of individuals being able to exercise control over various aspects of their own learning. It could be argued that current trends in educational thinking which favour giving more control and autonomy to the learner would appear to be more in line with the thinking of researchers such as Schneiderman (1983) who favour 'direct manipulation' over the development of interactive agents with a significant degree of independence of action. There is certainly a case for suggesting that pedagogical agents be configured so as to be particularly sensitive to individual user models, more responsive to instruction from the user/student, and that their characteristics and capabilities should be more transparently presented.

A high degree of transparency in relation to the functioning, indeed to the existence of agents within the electronic classroom is also important in relation to maintaining a level of trust which many educators believe to be an important component of any learning environment, whether computer based or face to face.

A further concern in regard to the autonomy of pedagogical agents relates to the issue of intervention in the learning process. It is well accepted that a high degree of unsought assistance whether from a human teacher or an excessively diligent and proactive agent can be quite detrimental, in particular to the metacognitive aspects of learning. The fact that this is also an issue for teachers and learners in face to face educational contexts underlines its complexity, and degree to which it is unlikely to handled with the requisite sensitivity through prior programming of an agent.

An interesting aspect of most agent based educational systems is their use of a multiplicity of agents, many of them capable of a complex range of interactions with the student, with one another, and increasingly with agents associated with other programs. These interactions range in nature from collaboration to competition, and their purposes are derived from theoretical analyses of the various component tasks and activities that make up the human activity of 'teaching'. An example is the Multiple Agent Tutoring System (MATS) described by Solomos and Avouris:

"MATS is a prototype that models a "one student-many teachers" learning situation. Each MATS agent represents a tutor, capable of teaching a distinct subject. All MATS tutors are also capable of collaborating with each other for solving learning difficulties that their students may have" (Solomos & Avouris, 1999, p. 243).

While on the one hand, the variety of functions of agents within a multi-agent environment is an attempt to realise the type of rich user interface which Johnson suggests is necessary if the pedagogical interactions within electronic learning environments are to approximate to any degree to the face to face educational experience, some educators have concerns in regard to the assumptions underlying these practices. They argue that such developments are underpinned by a reductionist rather than a holistic understanding of the processes and relationships involved in teaching and learning. In separating out the different components of pedagogical interactions, are we enabling each part to be realised more effectively, or are we failing to acknowledge that the global act of human teaching may in fact be more than the sum of its component parts?

Central to the work of many theorists and researchers is the belief that it is possible for agents to participate effectively in the social aspects of knowledge construction. Sheremetov and Nunez, for example, whose works derives overtly from the theoretical frameworks of Piaget and Vygotsky, argue that:

"The design of learning environments, virtual or not, aims to promote productive interactions. In this type of learning a student changes from being a passive information receiver to an active collaborator, interacting with the tutors and colleagues in the learning process. Learning does not only result from acquiring knowledge, solving problems or using tools, but also from interacting about these on-going activities with persons and agents( Sheremetov and Nunez 1999, p.305 – 306).

But however personified and autonomous the software agent, can it really be said to participate fully in the social construction of knowledge? It has been argued quite extensively that even the most heavily personified of computer programs suffer from an intrinsic lack of ability to participate in the metacognitive aspects of learning. Pufall (1988), for instance, expresses a strong belief that a computer program is unable at any
level commensurate with human capacities to modify its own knowledge structures or cognitive processes, and so cannot be regarded as a co-constructor of knowledge in a meaningful sense. While this might well have been the case in relation to earlier computer based learning environments, can we continue to make the same claims with confidence today or in the future? The capacity of software to ‘learn’ and adapt to experience through the incorporation of new information, the appropriate modification of its representation of the context in which it functions (its ‘world’) and of its inference mechanisms, is undoubtedly increasing. If our test of full participation depends on an understanding that the agent has ‘learnt’ in precisely the same way that the human has learnt, then we will have difficulty accepting the electronic entity as genuine co-constructor of knowledge. If, however, we make our claim on the grounds that it appears to the human learner that the agent has participated in the learning that has taken place, then perhaps we can at least tentatively admit such a piece of software to membership of the social milieu that has mediated the educational experience.

Conclusion

The widespread implementation of agent technologies within the electronic classroom is bound to raise a large number of issues of which those listed above are a sample. While it is critical that pedagogical concerns rather than simple technical capabilities are the driving force behind the development of these new learning environments, it is also important to look beyond the extent to which agents can simply replicate existing classroom conditions. Where agent based educational systems can be identified as differing from the traditional classroom, careful research and critical evaluation is required if we are to distinguish between those which simply undermine valued aspects of the educational enterprise as we understand it, and those which have the potential to create fruitful new possibilities in regard to how we teach and how we learn.

Creativity and Efficacy in Implementing a Guiding Partner Approach: Thinkquest for Tomorrow's Teachers PT3 Project

The ThinkQuest for Tomorrow's Technology project funded by the USDOE is in its second year of work as a catalyst grant. ThinkQuest and fourteen universities are partners in the implementation of work to prepare preservice teacher education candidates to use technology effectively to enhance teaching and learning.

The ThinkQuest for Tomorrow's Teachers project informs university students of the Guiding Partner Approach (GPA) based on student-centered constructivist pedagogy that requires student-to-student and student-to-faculty "elbow to elbow" learning. As students explore their understanding of important academic content for K-12 learning, they also decide on how to use internet-enriched activity design to help to display interesting resources from their research on curricular topics. They also work with their peers and teachers as collaborators, researchers, and co-facilitators, so that they experience the benefits of collaboration, rather than individualism and isolation. This approach to learning will provide a model to students of a new ideological foundation for work in systems such as K-12 education.

In the second year of implementation, faculty at each of the fourteen universities are incorporating digital and internet technologies as skills to be learned and as opportunities for teams of students to work together in creating educational web sites with information and activities of interest to youth, teachers, and university pre-service teachers. At the lead university, the University of the Pacific, teams of students, from team sizes of two to six students, in selected courses in the School of Education have prepared web sites with content relevant to topics they are learning in their course work as well as content and pedagogy pertinent to state academic content standards.

Key to this understanding of the guiding partner approach are insights provided by Judi Harris in her book, Virtual Architecture: Designing and Directing Curriculum-Based Telecomputing (1998, ISTE) as she states, "How to apply the tools in curriculum-based educational activities, although less frequently the target of careful thought and in-depth investigation, is a much richer, more complex, longer-term, and more critical area for educators to explore at this point in time. In short, it's not about how teachers use the TOOLS—it's about the USE of the tools" (pp.5-6).

This paper presentation will focus on the results of collaborative work by university students on digital web sites to understand their sense of efficacy in researching academic content and in learning to use the digital and internet technologies. Also, the paper will focus on a relationship between imaginative and creative development of content and students' skill in using the technology. We have observed that as students became creative in their thinking about the content, they correspondingly became more interested in finding interesting ways to display the content in the digital environment.

As an example, students in an Introduction to Language and a Children's Literature course were required to develop web sites as courses assignments. Students in the Introduction to Language course had course paper assignments leading to the web page assignment that required them to investigate information about a topic of interest to them in several areas of language study. Students were invited to research any one topic among several topics such as research in second language acquisition, modern and classical languages, logographic representations of language, language and reading, and dialects in American language communities. Students first developed, individually, annotated bibliographies of ten sources of information from scholarly publications. Then, they prepared conventional five page papers on the topic, using sources uncovered in the annotated bibliography assignment. Students were then asked to group themselves with others in the course who wrote on topics in the same area in order to develop teams to work on development of a web site by each team.

When students first developed ideas about their web site, they organized very brief planning outlines or story boards for their web sites. Students then participated in a brief presentation on the use of a web editor software product. In the teams, students were assured that no one had to be an expert on the content or the
digital technology skills, and they were encouraged to work together. Students then investigated how to apply the technological skills to design the artistic backgrounds for their web sites and to include content for the sites. Students also discovered that some of their peers had some background in using web editors, and those students took on a role of teaching others how to use the web editor and its functions. We observed that as students became more confident about the use of the web editor and some of its functions, they also designed creative presentations, with a range of sophistication in the look and content for their sites. Some sites were novice web sites, providing presentations of information from paper based materials, and others were more imaginative web sites with interesting graphic design and use of the web functions and capabilities.

Students in a Children's Literature course also worked in teams to design and implement a web site on a children's book and author. Similarly, students planned out the organization of their web site with story-board-like plans. They worked on ideas for the web site to be a comprehensive tool for a child so that the child could develop comprehension skills and higher level thinking through activities and features of the web site. These students also became more creative and imaginative about their web site and the potential for interactivity and design elements as they became more comfortable with the web editor and as they thought more creatively about the content.

This paper will present work-in-progress with a sample of web sites from student teams and excerpts from their written reflective papers about their progress in the creative process and change in their sense of efficacy as they worked with academic content material and the web editor and its capabilities.

The experiences of these students is illustrative of the purpose of the ThinkQuest for Tomorrow's Teachers grant: To prepare new prospective teachers to be able to combine practice in the Guiding Partner Approach and the use of internet technologies and content knowledge, so that they develop an ideological basis for professional work that encourages exploration, collaboration, and constructivist pedagogy.
The New Scholar's Interface: Virtual Image Technologies Compared

James M. Duncan, M.L.I.S., Hardin Library for the Health Sciences, The University of Iowa Libraries; Fred R. Dee, MD, Department of Pathology, The University of Iowa College of Medicine

Abstract
Virtual slide and virtual image technology has the potential to revolutionize the way we teach and share microscopy and other kinds of high-resolution images. This technology applies to not only student-focused instructional media, but also to historical research and web-based publishing. In this paper, the authors compare functional aspects of "virtual image" technologies based on Flashpix, QuickTime VR and other formats. Advantages and disadvantages of each format will be discussed with regard to the content of images, the target audience and the pedagogical purpose. This paper also will discuss some details about technical requirements and basics of authoring.

Why Use Virtual Images?
Increasingly, libraries and academic departments are digitizing and delivering image content for use by researchers and students. In many cases such projects involve web delivery of static images no greater than 72 dpi. This may be sufficient if the content of the image and end-use of the image does not require more than low resolution. However, for intensive analysis and study, higher resolution alternatives are often preferred. Desirable functional mechanisms for interacting with such high-resolution images include the ability to magnify or "zoom in" on an image, pan across an image, or point to landmarks or highlighted areas of an image. Interaction with digital images introduces opportunities that can contribute to greater understanding, particularly when added-value contextual content can be naturally incorporated within the image file itself or the interface within which the image is displayed.

For several years, staff and faculty members at the University of Iowa Libraries and the University of Iowa College of Medicine have been working with high-resolution image content and various methods of delivering that content. In one project involving a formative evaluation of virtual slides used during a first-year histology laboratory, students rated these images equal to the traditional microscope in terms of image quality and utility, and rated them superior in terms of learning efficiency and ease of access. (Harris, et al., 2001). In another project, high-resolution representations of rare anatomical illustrations were rendered in a QTVR format and delivered to the web (http://www.lib.uiowa.edu/hardin-www/mascagni/). Project planners are continuing to explore mechanisms for studying and evaluating how this format (and its interactive functions) impacts the way in which individuals conduct historical research.

The question of when to utilize one particular virtual image format over another depends on several factors: file size and resolution of the digital source; degree of detail required for end use; server resources available for storage and delivery; availability of technical expertise; and budget.
Microscopy Images
In the case of virtual microscope images, typical image acquisition involves the capture of contiguous fields, which are then tiled or stitched together to form one seamless large image. In cases involving a QTVR solution, producers have created virtual image files with starting source files as large as 3,472 x 2,784 pixels (Trelease, 2000). "Hot spots" provide linkages between virtual images. For example, one virtual image captured at 10x magnification could be linked to another captured at 40x. The benefit to using QTVR is that it is based on an industry standard technology, Apple Computer's QuickTime (http://www.apple.com/quicktime/qtvr/). This is free system software already used by millions for playing and authoring multimedia. For the virtual slide project at The University of Iowa, producers captured up to 1,200 images at 640 x 480 resolution, each 300 dpi. After tiling these images, the source image for a virtual slide would be approximately 18,000 x 18,000 pixels, and in TIFF (tagged image file format) would consume close to 1 GB per slide. After compression in a FlashPix format, each slide uses approximately 125 MB of storage. Image quality is impressive in the end delivery of virtual microscope images, which can be accessed via a Java-enabled web browser. Regardless of the approach, a microscope equipped with a high-end digital camera or video camera is required to produce professional quality virtual slides. Of the two options presented above, QTVR is the most approachable in terms of technical expertise required; off-the-shelf software is widely available for producing such images. Production of microscopy images using the FlashPix approach involved significant storage capability, a customized server, and skilled personnel for media production and technical support, which translates to higher costs.

Historical Images
A library-based project where rare images from a special collection were delivered in the QTVR format is being considered the first-pass at working with this source content. Starting with 600 dpi images captured from professionally photographed 35mm slides, producers imported the images into QTVR Authoring Studio, an off-the-shelf software package. Using a variety of compression settings and exporting techniques, each image was produced as a QTVR object, providing zoom and pan capabilities. Hot spots were pre-authored, linking to more focused views of select portions of each image. One of the drawbacks to the format was that any zooming became centered in the middle of the image; to see a magnified portion of an image at the edge of the picture, an user must first zoom in and then pan across. Future project plans include re-authoring the virtual images using a different authoring tool, Zoomifyer, which will fix the zooming issue and will provide alternate file format delivery options, such as Java.

Applying the REAL Model to Web-based Instruction: An Overview

Scott Grabinger and Joanna Dunlap
University of Colorado at Denver
Scott_Grabinger@ceo.cudenver.edu – Joni_Dunlap@ceo.cudenver.edu

Abstract: This article deals with a significant challenge in education today: the challenge to teach life long learning and critical thinking skills in web-based environments. This is a challenge for two reasons. First, business and government are pressuring educational institutions to prepare employees who can think critically, solve a range of problems, move easily from one task to another, work in team situations, and continuously enhance their knowledge and skills. Second, consumers (i.e., students) desire more distant learning strategies. Most strategies that develop these skills emphasize small group work, collaboration, and teacher/group interactions. One approach to this challenge is to apply the Rich Environments for Active Learning (REAL) model to web-based learning environments. REALs are interactive, student-centered learning environments that rely on intentional learning, authentic contexts, generative learning activities, collaboration, and reflection to address the learning of content and life long learning skills.

The Collision of Two Educational Goals

Goal #1: Preparing People for an Ever-changing World

Changing global economic circumstances and increasingly complex societal needs place greater and greater pressure on education systems to develop learners who can apply knowledge and skills in new domains and situations. Both public and private institutions expect and demand employees who can think critically and solve a range of problems, move easily from one task to another, work efficiently and effectively in team situations, and constantly adjust and enhance their knowledge and skills to meet emerging needs; yet, these institutions claim that those people are difficult to find.

This isn’t too surprising. Conventional instruction often utilizes simplified and decontextualized examples and problems. This leads to inert knowledge (Whitehead, 1929) — knowledge that cannot be transferred to real problems and situations. Learners are not asked to take responsibility for their own learning — they do not set learning goals, ask questions to direct learning activities, assess their learning strategies and approaches, or reflect on what they have learned. This lack of focus on metacognitive and self-directed learning skills interferes with their ability to transfer their knowledge and skills to future needs. Therefore, to meet the goal of “preparing people for an ever-changing world”, instructional programs need to apply methods that focus on the development of higher-order learning skills including critical thinking, problem solving, research, and life long learning.

Goal #2: Learning at a Distance on Demand

The learning audience shapes the second goal — the demand for more distance education opportunities. Generally, most definitions of distance education include the concept of time- and space-independent teaching and learning. This includes the use of information and communications technologies, interactive video, and computer networks to enable asynchronous and synchronous learner-to-facilitator, learner-to-learner, and learner-to-content interaction. Distance learning alternatives help learners deal with a number of the personal constraints, obstacles, and needs:
- People live in remote geographic areas far from educational institutions.
- Local educational institutions may have a limited number of program options from which to choose.
- People have work schedules that conflict with campus-bound course schedules. This includes people who work shifts, travel frequently on business, work long hours, and are in the armed forces.
People have personal and family commitments that conflict with campus-bound course schedules including children at home and aging parents.

After a long day at work, people don’t want to battle traffic or parking to get to a campus on time (and encountering the stress caused by trying to is not the best way to start a learning activity).

Some learners may simply prefer a distance format over a face-to-face format because of their learning styles and preferences (e.g., more comfortable sharing ideas asynchronously).

**Coming to Terms with These Goals**

The tension created when these two goals collide is an instructional design one: On the one hand, how do you help people learn in a manner that enables them to transfer their skills and knowledge to a wide variety of situations; and on the other hand, how do you address the learning audience’s expectation for learning experiences available on demand in highly individualized ways? One approach to this conflict is the application of the Rich Environments for Active Learning (REAL) model to web-based learning environments.

**Rich Environments for Active Learning (REALs)**

A model for applying the concepts of constructivism to instructional practice, REALs are comprehensive instructional systems that engage learners in dynamic, authentic learning activities that increase their control and responsibility over the learning process while they learn problem-solving and collaborative skills and content (Dunlap & Grabinger, 1995; Grabinger & Dunlap, 1995; Grabinger, Dunlap, & Duffield, 1997; Kommers, Grabinger, & Dunlap, 1996). The REAL model utilizes the following instructional strategies:

- intentional learning and student responsibility
- authentic contexts and relevant, meaningful learning
- dynamic, generative learning activities
- collaboration and the social negotiation of meaning
- extensive reflection and self-assessment

**Encouraging Intentional Learning: Taking Ownership**

Intentional learning refers to the cognitive processes that have learning as a goal. Students engaged in intentional learning are purposeful, effortful, self-regulated, and active learners (Palincsar, 1990; Palincsar & Klenk, 1992; Scardamalia & Bereiter, 1985; Scardamalia, Bereiter, McLean, Swallow, & Woodruff, 1989; Scardamalia & Bereiter, 1991; Scardamalia & Bereiter, 1997). Encouraging students to take “an intentional stance toward cognition” helps students learn how to monitor their own thinking and learning processes (i.e., metacognitive skills), and to pursue individually determined learning goals (i.e., self-directed learning). When students take responsibility, or ownership, over their own learning, they develop metacognitive and lifelong learning abilities (Honebein, 1996).

REALs help students manage their own learning by identifying their learning needs, setting learning objectives, selecting and employing learning strategies, using appropriate resources, and assessing their overall process. Research (Scardamalia & Bereiter, 1991) indicates that students can assess what they know and don’t know and learn to ask questions to guide their knowledge building, thus assuming a “higher level of agency” and more ownership for their learning. To teach for intentional learning means to cultivate those general abilities that make it possible to become independent, lifelong learners (Palincsar, 1990).

**Authentic Contexts**

It is difficult to transfer learning from one situation to another. Learning is more likely to be transferred if instruction is situated within a realistic context (Brown, Collins, & Duguid, 1989). Anchoring learning in larger, more complex contexts helps prevent the acquisition of inert knowledge (Cognition and Technology Group at Vanderbilt, 1993). Because understanding is developed as a natural consequence of interaction with a
complex environment, learning activities should be authentic, reflecting the types of interactions students are likely to face in the “real world” (Honebein, 1996).

Authenticity is an important part of REALs for four reasons. First, realistic problems hold more relevance to students’ needs and experiences because they can relate what they are learning to problems and goals that they see every day (Blumenfeld, Soloway, Marx, Krajcik, Guzdial, & Palincsar, 1991; Pintrich, Marx, & Boyle, 1993). Second, authentic situations that reflect the true nature of problems enable students to develop deeper and richer knowledge structures (Albanese & Mitchell, 1993) leading to a higher likelihood of transfer to novel situations. Third, authenticity encourages interaction through collaboration, and negotiation (Johnson & Johnson, 1979; Lowry & Johnson, 1981). Finally, ill-structured, complex problems require a team approach that provides natural opportunities for learners to seek out information, test and refine their ideas, and help each other understand the content.

Dynamic, Generative Learning Activities

Learners are active constructors of knowledge—not just passive receptors of information. Generative learning activities require students—individually and collaboratively—to be responsible for creating, elaborating, and representing domain knowledge in an organized manner (Cognition and Technology Group at Vanderbilt, 1990, 1993; Hannafin, 1992; Scardamalia, Bereiter, McLean, Swallow, & Woodruff, 1989; Scardamalia & Bereiter, 1991). Through generative learning activities, learners take an active role in forming new understandings through the creation of products and solutions to authentic challenges. This process of “generating” knowledge—instead of passively receiving information—helps learners develop transferable knowledge structures, strategies, and the skills for life long learning.

Some generative learning activities provide students with a context or situation requiring them to take action (e.g., a problem that needs to be solved or a case that needs to be analyzed). For example, Schank, Fano, and Jona (1993) describe a generative learning environment in their discussion of the research method of teaching. Under the research method of teaching, students research a particular topic and then present their results to others (e.g., the class, a collaborative group, etc.). In this way, students take over the responsibilities of information gathering, synthesis, and dissemination from the teacher. To be successful, students need to be allowed to select their own topics to research and report on, so that they have a real interest in proceeding with the assignment and have more control over their learning. Because the learning is student-directed, the learning is more meaningful. Bruner (1961) states, “...in general, material that is organized in terms of a person’s own interests and cognitive structures is material that has the best chance of being accessible in memory”.

Collaboration

Learning takes place in a social context; higher cognitive processes originate from social interactions (Vygotsky, 1978). Lebow (1993, p. 6) states that knowledge acquisition is “firmly embedded in the social and emotional context in which learning takes place”. Thus, collaboration, conversation, communication, and establishing a community of learners are critical to the teaching and learning process (Pask, 1975).

REALs demand collaboration among students to achieve complex goals. By employing collaboration strategies, REALs help learners engage in a number of activities that support successful learning:

- **Collective problem solving.** Groups give rise synergistically to insights and solutions that would not come about individually. While working in collaborative groups, learners are more willing to take on the risk required to tackle complex, ill-structured, authentic problems because they have the support of others (Brown et al., 1989; Vygotsky, 1978).

- **Displaying multiple viewpoints.** Students experience and develop an appreciation for multiple perspectives when working with others. They may also play different roles within the group to gain additional insights. Conceptual growth comes from sharing perspectives and testing ideas with others—a negotiating process that modifies internal representations (Bednar, Cunningham, Duffy, & Perry, 1991).

- **Confronting ineffective strategies and misconceptions.** In collaborative work, group members draw out, confront, and discuss their misconceptions and ineffective strategies. Through collaborative participation, students also refine their knowledge through argumentation, structured controversy, and the sharing and testing of ideas and perspectives.
• **Providing collaborative work skills.** Students learn to work together in a give-and-take interaction rather than just dividing the workload. By participating in collaborative learning activities, learners gain an appreciation for the value of cooperation and the individual strengths that members of the team bring to the group.

**Reflection and Self-Assessment**

Self-reflection activities are embedded into REALs in order to support both the development of knowledge and metacognitive skills. Von Wright (1992) defines metacognitive skills as “the steps that people take to regulate and modify the progress of their cognitive activity: to learn such skills is to acquire procedures that regulate cognitive processes.” Glaser (1984) describes this as knowing what one knows and does not know, predicting outcomes, planning ahead, efficiently apportioning time and cognitive resources, and monitoring one’s efforts to solve a problem or learn. More specifically, metacognitive skills that are required for life long learning include (Ridley, Schutz, Glanz, & Weinstein, 1992):

- recognition of content and skill limitations;
- setting goals and creating action plans based on those defined limitations;
- activating the appropriate prior knowledge to achieve set goals;
- assessing progress in learning and task performance and effectiveness of learning resources selected;
- awareness of what still needs to be completed to reach a goal, and how best to allocate time and resources;
- and
- modification of strategies, tactics, processes, and resource selection based on the needs of the task at hand.

Even though reflective activity is important, it is possible for students to be so caught up in completing a task that they fail to reflect, impeding the learning process. “We can keep students so busy that they rarely have time to think about what they are doing, and they may fail to become aware of their methods and options” (Wheatley, 1992, p. 536). Schön (1983) refers to this as being “in the action” rather than reflecting “on the action.” If students do not have opportunities to examine their methods and options, they will not develop the metacognitive skills needed for life-long learning. Therefore, learning activities need to support students in reflecting on their own learning and problem-solving processes, as well as on what they have learned (Schön, 1987).

**Conclusion**

A consistent theme within each of the REAL guidelines is “interaction.” Interaction refers to the engagement of learners in the learning process. By engaged learning, we mean that all student activities involve active cognitive processes including creating, problem solving, reasoning, decision making, and evaluation (Kearsley & Shniederman, 1993). Interactivity involves the learners in options: watching, browsing, finding, doing, using, linking, annotating, constructing, creating, and elaborating (Ambron & Hooper, 1988; Sims, 1997). The use of technology does not diminish the importance of good pedagogy and good pedagogy demands interaction. This is especially true for web-based instruction with the critical need for learner-to-content, learner-to-learner/s, and learner-to-facilitator interaction.

Xtreme Learning Control: Examples of the Open Source Movement's Impact on Our Educational Practice in a University Setting

Joanna C. Dunlap, Brent G. Wilson, & David L. Young
University of Colorado at Denver

Abstract: This paper describes how Open Source philosophy—a movement that has developed in opposition to the proprietary software industry—has influenced our educational practice in the pursuit of scholarly freedom and authentic learning activities for our students and ourselves. This paper provides a brief overview of the Open Source movement, and describes three Open Source-inspired Web-based tools/environments developed to promote open sharing and constructing of scholarly work on the Web.

Overview

Do you know the story about the discovery of the structure of DNA? Or, the discovery of the Rosetta Stone cipher? Both are stories of not only brilliance, but also competition. Relying on the foundational work of Linus Pauling, Francis Crick and James Watson discovered the double helix. Then separately, relying on the foundational work of Thomas Young, Jean Francois Champollion deciphered the Stone's script. However, due to competition and secrecy, which kept all parties from openly sharing their findings (and possibly sharing the rewards of discovery...after all, whose name do you remember?), the progress of science may have been delayed. This type of competition is in direct conflict with the nature of science and discovery—a process of evolving exploration founded on the work of others.

Educators are concerned with the impact this type of competition and secrecy can have on their practice as well; educational innovation can be stymied by industry and individuals that perpetuate the politics and control over professional sharing and advancement—such as the publishing industry or the proprietary communication and collaboration software industry. Although some educators may hold secret the work they are doing to advance knowledge and practice around good teaching and learning, most are interested in advancing the collective understanding—in sharing insights, ideas, solutions, and materials that can help us all do our work more effectively. Educators are also interested in creating tools and structures that support the type of learner-centered, collaborative knowledge sharing that can lead to discovery and innovation. Often, educators are stymied in these pursuits due to excessive proprietary software costs and dwindling institutional budgets.

This paper describes how Open Source philosophy—a movement that has developed in opposition to the proprietary software industry—has influenced our educational practice in the pursuit of scholarly freedom and authentic learning activities for our students and ourselves. This paper provides a brief overview of the Open Source movement, and describes three Open Source-inspired Web-based tools/environments we have developed with our students and colleagues to promote open sharing and constructing of scholarly work on the Web.

Open Source Movement

Encouraging innovation through open sharing to facilitate replication and discovery, the Open Source movement is a grassroots revolution that has taken shape in the world of information technology. The Open Source movement is challenging the commercial model of technology advancement, exemplified in the software industry by Microsoft. Linux, an operating system whose source code is open for the world to see and costs nothing to download and use, has become a significant force for change in the software development world. Other information technology products emerging from the movement include Netscape/Mozilla, Apache, Perl, and GIMP. Open Source advocates are trying to create a world where software is openly...
available and a living is made through continuing relationships of service and support. These same Open Source ideas are influencing our teaching and learning practice. The following are three examples of how Open Source has impacted our work with students at the University of Colorado at Denver.

Self-Publishing: NOVAtions Online Journal [in Joni's voice]

A year ago, I was informed that it was my turn to teach a doctoral course focused on instructional technology during the upcoming fall semester. This course is part of a doctoral program in educational leadership and innovation, and – as such – the participating doctoral students were interested in a wide range of educational foci: teacher education, paraprofessional preparation, teaching and learning in K12 and adult settings, and technology-enhanced learning. In preparing for the course I anticipated insightful, yet challenging, discussions and collaborations given the diverse backgrounds and interests of the students. I realized that there was no way for me to be the “expert” in all of their interest areas during our experience together, and that I didn’t need to be because the students were emerging experts in the topic foci they were studying. So, I looked for a way to create a unifying theme and project while at the same time taking advantage of the developing expertise of the students to create a valuable learning experience for everyone – including myself. To this end, we built a grassroots online professional journal.

NOVAtions is an online journal for emerging scholars built using the Slashdot.org Open Source code (see http://novations.opencentric.com). Slashdot.org is an online self-organizing social system (OSOSS) (Wiley & Edwards, 2002) that is a Web-based news source in which the readership contributes and reviews news items, and has significant influence and control over the direction of and themes covered by the site. Our NOVAtions journal is designed to provide a forum for a community of practice – scholars interested in educational innovation in teaching and learning. Contributors to the journal also function as the editorial review board, in much the same was as Amazon and Barnes and Noble enable the book buying public to serve as reviewers.

The doctoral students in my course built the NOVAtions journal from scratch (see Figure 1). Self-publishing the online journal provides the doctoral students with an authentic, enculturating leadership experience in which they:

- publish articles and collaborative book reviews to learn more about the process of sharing scholarly ideas with others and publishing ideas in a journal, and
- serve as the editorial review board to learn about the editing process and improve their own writing.

![Figure 1: Students self-publishing in NOVAtions online journal](image)

This fledgling journal was launched in December 2001, and plans are now in the works to extend the journal participation to the larger community of practice in educational leadership and innovation.
Knowledge Sharing: *Web Resource Collaboration Center (WRCC)* [in Joni’s voice]

The Web Resource Collaboration Center (WRCC) (Dunlap, 1999) is a Web-based tool which empowers learners to build their own Web-based resource centers – using the Web to provide on-demand access to integrated information, guidance, advice, assistance, training, and tools – to support their learning, professional development, and performance.

A few years ago, I was hired by an information technology organization to “get to the bottom” of why its elaborate electronic performance support system (EPSS) which was available on the company’s intranet was not being utilized by employees. The company had used its training and development resources to build this EPSS to help employees keep up with all of the new technologies they were expected to master for the various contractual projects of the organization. Since a front-end analysis was not actually conducted before the development of the EPSS, this is where I started. The employees were pleased that the EPSS provided a variety of resources (e.g., tutorials, white papers, job aids, business cases, etc.) to support their various learning needs and preferences. Instead of conventional training, they wanted access to learning and professional development resources that would help them keep their knowledge and skills “cutting edge”.

Although they were not against the idea of an EPSS, the employees did not believe that the developers of the EPSS understood what resources they needed. In addition, they certainly believed that developers did not know how to present them in contextualized ways (e.g., resources that would help with one type of project vs. another type of project). They were also concerned that there was no way to capture the “here’s how I did it” expertise of the people in the organization, and in the external community of practice. Finally, the EPSS was static. This was in sharp contrast to the constantly evolving information and tools these employees were using. The most up-to-date information was being distributed on the Web. The EPSS was not dynamic enough to capture those changes, so the employees were using the Web to support their learning and professional development – albeit not very efficiently which led to frustration. Bottom line, the employees had been cut out of the process, and believed that they were better judges of what was needed to support their learning and work.

This consultation led to my interest in developing a tool that would (1) take advantage of some of the structural qualities of EPSS, (2) harness the resources on the Web (since it was a distribution source for some of the most up-to-date information and tools), and (3) provide a structure for learning communities and communities of practice to build their own unique content to support both lifelong learning and professional development activities. To meet this challenge, we created a Web-based development tool called the Web Resource Collaboration Center (WRCC).

By creating a structure that supports individualized and collaborative knowledge building by the people who will actually be using the knowledge, the higher-order thinking, problem-solving, and decision-making involved in the selection and utilization of appropriate learning materials and performance support is done by those who can get the most out of the process. Additionally, because these activities occur in the workplace and are driven by the needs of the job at hand, the learning activities are contextualized, authentic, and meaningful. The WRCC meets the following goals:

- The users learn about the domain while they are locating, evaluating (which requires utilization of resources), organizing, and creating resources to support their learning and job performance activities – making the process relevant and productive;
- The content of the WRCC is information that has been applied/articulated from the perspective of reflective practice, making the WRCC a knowledge management forum;
- The WRCC is developed by and for the people involved in the project, challenge, or domain; and
- The WRCC can change and adapt based on the changing organizational and learning/performance needs because the end-users control the content.

In this way, the WRCC not only enables learners to build a learning and performance resource that will provide them with immediate support and guidance, but also helps them develop structure, strategies, and skills for subsequent learning activities.

To provide a structure for these activities, the WRCC is broken into three functional areas: the Discussion Forum, the Link Manager, and the Resource Construction System (see Figure 2). These tools – written entirely in Perl – are not unique – there are similar tools available from a variety of sources. The impact is in the use and integration of the tools, and the fact that they are Open Source and support learner-centered knowledge sharing.
Figure 2: Examples of WRCC’s Link Manager, Discussion Forum, and Resource Construction System

Once built, I recognized the value of this type of tool for learning communities in general, including the students I work with at the university. The WRCC is being used to support instructional activity in both face-to-face and online courses, and as a performance support and knowledge management tool by self-organizing learning communities (see http://carbon.cudenver.edu/public/wle/wrcc/techfork12/ for an example of a WRCC).
Self-Organized Learning and Performance Support Groups: *Electronic Knowledge Base (EKB)*

In our Information and Learning Technologies (ILT) Master's program, we organize students into cohorts. As a cohort, students progress through the program together, and quickly develop a professional bond that lasts beyond the program. One ILT Master's cohort of 20 K-12 teachers shared a common purpose of learning how to best integrate technology into their instruction, classrooms, and schools. This group was constantly sharing their views, understandings, and opinions, as well as information and research they unearthed. This collective base of knowledge was the lifeblood of their common endeavor, and they wanted to "capture" the knowledge they were discovering and constructing with each other.

Inspired by Jonassen, Peck, and Wilson's (1997) note that "learning and knowledge-building communities depend heavily on ... a rich collection of information and learning resources to support them," this cohort designed and developed Electronic Knowledge Bases (EKBs) using adapted Perl scripts available at no charge to educational institutions (Young, 2000; see http://carbon.cudenver.edu/public/ilt/pages/). They used the EKBs as a way to formalize the process of collecting a rich source of knowledge resources. These databases served as an easily accessible and amendable repository of knowledge assisting them in their search for specific information and research related to teaching and learning. The EKBs supported their efforts as a dynamic learning community, and became a source of knowledge for other educators not participating in the ILT Master's program (see Figure 3). Dave Young, then a student and more recently a faculty colleague and co-author, was the primary developer of the resource.

![Figure 3: EKB Homepage, Detailed View of Contribution, and Resource Review Feature](image-url)
**Peer-to-peer networking: Our Next Adventure**

Although we haven't implemented peer-to-peer networking in our environment, we are very intrigued by the possibilities and planning it as a next step in our adventure in reclaiming learner control. Peer-to-peer networking refers to individual users sharing resources by opening up their hard drives to each other – a group of computers communicate directly with each other, rather than through a central server. Besides potentially having a positive impact on collaboration and knowledge sharing, it can also make good technical, infrastructure sense – if computing power and resources are distributed then no one server or network connection is over-taxed.

The Napster phenomenon taught us that downloading from central servers is not the only way to perpetuate an online enterprise. The core concept is even more radical than Napster’s, because once out of the bag and in the hands of end users, true peer-to-peer usage cannot be controlled. In this way peer-to-peer networking constitutes a classic form of self-organizing system, using the technology to bypass every form of central control and put the control in the hands of learners.

**Conclusion**

The Open Source movement is a reenergizing catalyst for our reclamation of learner control. Influencing how we think about supporting collaboration, knowledge sharing, and teaching and learning in general, we are embracing the message of Open Source with open arms. The three examples described above – as well as the work being done by colleagues at other institutions, such as Utah State University’s SlashLEARN project (Irving, 2001; see http://www.slashlearn.org/) and StorageTek’s COSS project (Ryder & Wilson, 1997) – have inspired us to continue to enrich our practice and our students’ learning experiences through the integration of Open Source-inspired tools and environments. We bok forward to sharing our projects and implementation results with our ED-MEDIA colleagues.

Using Technology to Create and Enhance Collaborative Learning

James D. Dvorak
North Institute for Educational Technology
Oklahoma Christian University
United States
jim.dvorak@oc.edu

Karen Buchanan
Director of Teacher Education
Cascade College – Branch Campus of Oklahoma Christian University
United States
kbuchanan@cascade.edu

Abstract: Oklahoma Christian University has implemented a ubiquitous computing program where every student and faculty member are equipped with IBM ThinkPad laptops that connected to a wireless network. The technological enhancements provided by this program helped to create an environment where collaboration between students and faculty could be increased. During the first full year of implementation, one course typically taught in a lecture-based format was re-designed to foster more collaboration and active learning. The instructor enhanced the course with collaborative technology, delivered most of the first exposure to the materials online, and created collaborative assignments to be done during the classroom time. A survey and several interviews were conducted to glean student feedback. Students found the course challenging and they rose to meet that challenge.

Introduction

Oklahoma Christian University is blazing a new trail with the e-campus concept instituted in the Fall of 2001. "The new technologies provide opportunities for creating learning environments that extend the possibilities of "old" (Bransford et al., 1999). Oklahoma Christian launched its wireless e-Campus in the Fall of 2001 by distributing IBM ThinkPads with wireless networking capabilities to every full-time student. It is the first university in Oklahoma and one of the few nationwide that offer to all students a wireless campus and laptop computers. Students can access the Internet or myOC (the university's personalized, web-based portal) from virtually anywhere on campus. Such a culture change affects not only students, but also faculty. For some, this culture change is an easy adjustment; for others, a seemingly insurmountable hurdle. Yet, the change affects everyone and it demands adjustments in the way teachers teach and students learn.

The use of technology does not guarantee that effective learning will occur in a course. Bransford, Brown and Cocking (1999) say that technology can, in fact, hinder learning if used inappropriately. However, when used appropriately technology can connect teachers, the instructional experience, and learners in ways that enhance learning (Newby, et. al. 2000). The goal of this collaborative effort is to use technology as an instructional intervention in the creation of an effective learning environment that is based on current research regarding how people learn.

Integration of Pedagogy and Technology

The Office of Educational Research and Improvement of the U.S. Department of Education charged a 16 member committee with the task of evaluating new developments in the science of learning (Bransford, et al., 1999). This committee reviewed research and consulted with experts in the process of
reporting the most current information regarding how people learn. Their recommendations are instructive for all educators.

These new conceptions of learning have created a shift from an emphasis on rote learning and repetition to a focus on depth of understanding and the ability to apply new knowledge. The implications of this new focus require new or renewed instructional interventions and learning environments (McLaughlin and Shepard, 1995).

The foundation of the classroom model that follows is a learner-centered approach to education. This model is steeped in collaborative learning and has a strong emphasis on formative assessment (Poindexter et. al, 2001). This discussion continues by exploring each aspect of this model course

“Learner-centered” environments value the knowledge, skills, attitudes, and beliefs that learners bring with them to the classroom (Bransford et al., 1999). The conceptual knowledge and beliefs that students bring to the classroom are the starting point of instruction. The pre-assessment in the model class purposefully investigates the knowledge that students are initially bringing to this course.

Learning is greatly influenced by the context in which it occurs. Instructors are charged with creating a learning community that facilitates students sharing their preconceptions, questions, and taking learning risks in pursuit of academic growth. Cooperative and collaborative learning are strongly supported instructional tools in the research literature. They have been shown to lead to cognitive development (Johnson and Johnson 1984; Slavin, 1991; Sharan and Sharan, 1989/90; Bransford et al., 1999).

The model course that follows requires students to read and listen to lectures outside of the classroom so that classroom time can be spent on collaborative pursuits. Students are placed in learning teams as they work through multiple milestone assignments. They will also produce a capstone project. The instructional technology embedded in the course encourages collaboration beyond the four walls of the classroom. Students may use Microsoft NetMeeting to work together online, as well as communicate and collaborate with the instructor. Synchronous chats, message boards and email will provide students with the opportunity to receive feedback from peers outside of their learning team. The instructor will serve as a guide, but students will be charged with directing their own learning. Student-involved learning has a strong link to academic achievement (Stiggins, 2001).

A unique and innovative aspect of this course is its use of formative assessment. Educators of the twenty-first century are functioning in an assessment climate that is almost completely focused on summative assessments (Stiggins, 2001). While these summative assessments provide very specific information about what students know, they do little to promote learning (Gallagher, 2000; Stiggins, 2001). Dylan Wiliam (2000) defines summative assessment as assessments that are “used to certify student achievement or potential” (p. 1). He goes on to describe formative assessments as assessments that “provide feedback to learners about how to go about improving” (p. 1). Crooks (2001) talks about formative assessment as assessment for learning. Several research projects highlight the connection between formative classroom assessment and academic achievement. Professor Terry Crooks (1988) of the University of Otago, New Zealand conducted a synthesis of over 200 studies on the use of formative assessment. He concludes that formative classroom assessment can have a very positive impact on student achievement. He further chronicles the connection between classroom assessment and student decision-making. “The decisions students themselves make, he (Crooks) contends, are the decisions that determine what is learned (Stiggins, 2001). “It [classroom assessment] guides students’ judgments about what is important to learn, affects motivation and self-perception of competence, structures their approaches to and timing of personal study…consolidates learning and affects the development of enduring learning strategies and skills” (Crooks, 1988, p. 267).

English researchers Paul Black and Dylan Wiliam (1998) conducted a meta-analysis of more than 40 controlled studies centered on the impact of improved classroom assessment on student achievement as reflected in summative assessments. They asked three questions in this project:

- Is there evidence that improving the quality and effectiveness of use of formative assessments raises student achievement?
- Is there research evidence that formative assessments are in need of improvement?
- Is there evidence about the kinds of improvements that are most likely to enhance student achievement?

The results conclude a resounding “yes” to all three questions. The results cross all content areas, knowledge and skill types and all levels of education. Results reveal unprecedented gains in achievement. They report effects between 0.4 to 0.7.
An effect size of 0.4 would mean that the average pupil involved in an innovation would record the same achievement, as a pupil in the top 35% of those not so involved. An effect size gain of 0.7 in the recent International comparative studies in math would have raised the score of a nation in the middle of the pack of 41 countries (e.g., US) to one of the top five.

Strong evidence supports the use of formative classroom assessment. This model course provides multiple opportunities for students to receive feedback from the instructor and fellow students so they can adjust their learning. It also provides opportunity for the instructor to assess students and then make instructional decisions based on those assessments.

Current research encourages educators to “Explore the potential of new technologies that provide the opportunity to incorporate formative assessment into teaching in an efficient and user-friendly manner” (Bransford et. al., 1999, p. 39). This model course is an exploration of that potential.

Case Study Context

The model course consisted of 37 freshman-level students. Eighty-three percent of the students were between 18 and 20 years old; 10 percent were between 23 and 24 years old; and 7 percent were 25 years old or older. Sixty percent of the class was male, 40% were female. There were only three international students in the course, one from Venezuela, one from Australia, and the third from Africa. Ninety percent of the students lived on-campus and, therefore, had 24/7 access to the technology described above.

The model course was designed to make heavy use of technology, yet the technology was meant to be “transparent,” used as a tool of the trade (much like a pencil or textbook). Priority was given to student learning. If the technology inhibited student learning, it was changed or removed. This course was designed so that it could be offered as a hybrid course (i.e., a course that has both F2F and online components) or as a distance education course.

The course followed a 20/80 rule (sometimes 10/90), meaning only be about 20% of face-to-face (F2F) time was used for lecture while about 80% of the F2F time was designated for students to collaborate on assignments or for in-class presentations (Poindexter et. al., 2001). To accomplish this, every lecture meant to give the students first exposure to the material was moved outside the classroom and into the Blackboard course management system (Walvoord & Anderson, 1998). Each lecture was accompanied by the instructor’s notes. The learners logged into the Blackboard course site, clicked into the lecture area, and listened to the lecture prior to the class meeting. These lectures consisted of digital audio of the instructor (or guest lecturer), accompanied by PowerPoint slides which were synchronized with the recording. The student could stop, play, pause, or resume these presentations. Moreover, s/he could jump ahead or back in the presentation by clicking a hyperlink to the desired slide. These lecture materials were available to the students for the entire semester (and beyond) and could be reviewed at the discretion of the student. After listening to the lecture, the students took quizzes over the material that was introduced (all quizzes will be given online using the built-in assessment feature in Blackboard). The instructor reviewed the scores of this assessment and adjusted the 10%-20% classroom lecture time for remediation as necessary. Other than these quizzes, no exams were given in this course.

The students were grouped into teams in order to collaborate on assignments and the final project. The groupings were based on several criteria:

- results of the Keirsey version of the Myers-Briggs temperament analysis
- learning styles
- self-selection (limited)

(Poindexter et. al., 2001)

Teams collaborated on multiple milestone assignments and one final project. The milestone assignments demonstrated the learners’ abilities to identify and accomplish the steps in the interpretive process. Each team chose a passage from The Acts of the Apostles and they worked on that text throughout the semester. These passages were the subject of the milestone assignments as well as the final project. The milestone assignments were primarily written assignments, but occasionally students were asked to present their work in class.
The final project had two parts. First, each team submitted an interpretation paper to their instructor in which they offered and defended an interpretation of the passage from Acts they chose. Next, each team gave an in-class presentation of their interpretation. This presentation required the use of a technological medium for its delivery. The student could have chosen from PowerPoint, digital video, web sites, or some other digital medium. Their presentations could not exceed 20 minutes in length, in order to allow time for critical peer review. The team of students filled the role of teacher during these presentations.

The instructor provided several ways for students to communicate with him and even collaborate on assignments as necessary. First, Blackboard has many built-in features to allow this: e-mail, message boards, and the virtual classroom (i.e., synchronous chat), to name a few. Moreover, the instructor had embedded Microsoft NetMeeting into a web page and uploaded it to the Blackboard course site. He pre-configured the software to call his computer at the click of a button. NetMeeting allowed the learners to call the instructor over the Internet and collaborate with him on the assignment or to simply receive feedback. For example, if a student needed feedback on a milestone assignment, s/he may call the instructor using NetMeeting. NetMeeting allows application sharing over the Internet, so s/he could open the word processing application, share that application through NetMeeting, and give control to the instructor. Then the instructor could actually mark up the student’s document with comments, suggestions, and corrections as necessary. This allowed for more than just feedback; it also allowed the student (or team) to actually collaborate on an assignment with the instructor.

The instructor provided several ways for the team members to collaborate as well. First, they, too, could have used NetMeeting for collaboration in the same manner described above (NetMeeting allows multiple users to connect with each other). Next, the instructor enabled the groups feature in Blackboard. Each group could collaborate using message boards, chat, e-mail, and file sharing—all of which are built into Blackboard. Each team had its own message board, chat room, e-mail address, and digital drop box, and those tools were only open to members of the same team.

The instructor provided all reading and research materials to the student in at least one of the following ways:
- digital format via Blackboard (articles will be scanned to PDF and uploaded to the content areas of the course web site in Blackboard)
- on reserve in the university library
- links to content available on the Internet and World Wide Web.

Those items that could not be provided were listed in a digital bibliography so the students could order items from the library using the Interlibrary Loan service or found them on Net Library in e-Book format.

**Findings and Discussion**

A survey was conducted at mid-term of the course and several interviews with students were conducted at various times throughout the semester. Each of these assessments revealed some interesting information. First, 50% of the students agreed or strongly agreed that the technology used in this course enhanced their ability to learn the material. The students found themselves interacting with the material and with each other more in this course than in any of their other courses. Because the lectures were online and because the technology allowed them to communicate with each other so much easier, they found themselves engaged in the course material even on days the class was not meeting.

The survey and the interviews uncovered another interesting fact. On the survey, the students were asked if they agreed or disagreed with the following statement: “If given the opportunity to take this class again, I would choose an Acts class with a more traditional lecture format.” Fifty-four percent of the students agreed or strongly agreed with this statement, 20% were neutral, and 27% disagreed or strongly disagreed. However, several interviews with different students enrolled in the course revealed at least one reason why they would have chosen lecture-based course: it is easier. Every student interviewed commented that this course was very demanding, whereas lecture-based courses are not as demanding because “all you have to do is show up, memorize facts for the exam, regurgitate those answers on the exam, and that is it. There are really no assignments where we have to work, like there are in this class.” Students will, however, rise to meet the expectation of a course. While there are many factors contributing to one class’s grades being higher, it is still interesting to compare grades from this course and the same course taught in a lecture-based format (see Tab. 1).
It appears that students in the technology-enhanced, collaboration-heavy course performed better than those in the passive, lecture-based course.

Finally, it was also discovered that students enjoyed working on the assignments in teams. As one student put it, “There was still pressure to do the assignment and to do it well, but pressure on a team is a lot different than pressure on a single individual.” In the beginning, there were grumblings about the way teams were chosen, but those grumblings ceased and even turned into positive results. One student remarked, “At first, I didn’t like the team I had been placed on, but as the semester went on, I developed a strong relationship with my team members— I trusted them to do their best and they trusted me to do my best. When I needed help, they helped; when they needed help, I helped.” Yet, as is normal, there were a couple of dysfunctional teams. Usually, the root of the dysfunction was related to external circumstances and not issues within the group.

There were also several lessons learned during this course. One lesson shows that while technology makes it easier to collaborate, students still desire face-to-face contact with the instructor and other students. Interestingly, the students enjoyed and even wanted the collaborative technology in place—and they used it. However, they also wanted a high level of face-to-face collaboration. Many of the teams worked out schedules of when they would meet online and when they would meet face-to-face. When meetings were online, usually every team member was “present” at the meeting; face-to-face meetings were not as well attended, but the quality of the meeting at the face-to-face meetings was often better than those conducted online. According to those who reported this fact thought it was due to the level of focus or distraction: there tended to be a greater focus at the face-to-face meetings and more distraction at the online meetings.

In terms of the collaborative technology provided for the students (e.g., Microsoft NetMeeting), the students tended to find their own technology for collaboration. By far the most popular was instant messenger software that the students obtained on their own. A close second, however, were the collaboration tools built into the Blackboard course management system.

**Implications of this work for Oklahoma Christian University**

This course provides faculty with one possible teaching model that integrates technology and pedagogy. This model is based on current pedagogical research. Moreover, the model serves as a stimulus for conversations regarding best teaching practices in classroom instruction at the college level.

The course also provides a model for teaching a course via distance education. As mentioned, the model course was designed in such a way that it could be taught in a face-to-face setting or a distance education setting.

**Implications for Other Institutions**

We would like to encourage other institutions of higher learning to have conversations about best pedagogical practices and how technology can facilitate learning in classroom settings.

Adoption of Computer-Based Instructional Methodologies: A Case Study

Samuel Ebersole, Ph.D.
Instructional Technology Center
University of Southern Colorado
ebersole@uscolo.edu

Marge Vorndam, M.S.
Instructional Technology Center
University of Southern Colorado
mvorndam@uscolo.edu

Abstract: Qualitative data collected from 24 lead faculty members at a regional comprehensive university were analyzed to discover barriers and incentives to the adoption of educational technology. Leading barriers to adoption of educational technology are; time, resources, and lack of confidence in the benefit of educational technology. Incentives that were mentioned included; because it’s the right thing to do, personal satisfaction, and student demand. The effect of mentor role models, modeled use of educational technology, and other exposure to educational technology methodology is also discussed.

Introduction

One of the challenges for implementing technology-based learning on college campuses is providing support for instructors who are already motivated to engage in new approaches to teaching and learning. Another challenge is to provide the initial motivation that will convince faculty that the time and effort required by these new approaches is justified. The University of Southern Colorado in Pueblo, Colorado is a regional comprehensive institution that has begun to address both of these challenges with an innovative program which supports faculty who are early adopters with the time and resources necessary to develop showcase projects. These projects in turn will be used to attract and recruit other faculty within their colleges, hopefully inspiring them to take the plunge into the world of technology-enhanced teaching and learning.

The use of educational technology on the USC campus has been, until recently, determined on an individual basis, or departmentally. In 2000, Blackboard course management software was installed on campus. In the same year, the University developed a strategic plan that recognized the importance of educational technology to teaching and learning. And most recently, the faculty handbook was modified to include appropriate use of educational technology as a criterion on which faculty performance is evaluated.

A national survey found that almost 47% of classes were taught utilizing web page supplementation nationwide at public universities (Green, 2001). Currently, approximately 33% of the University of Southern Colorado’s classes employ web pages as adjunct information for student use. At 55% of participating universities, including USC, on-line course management tools, e.g., Blackboard, WebCT, or e-education, are provided. On other campuses with course management capabilities, 22% of classes were offered using these tools, whereas, at USC...
approximately 18% of all courses utilized the on-line supplemental interface. Nationwide, 34% of all faculty members have their own web pages, whereas at USC less than 20% of faculty members do so. USC is among those institutions that; require all students to take a mandatory introductory computer class, offers supportive instructional training for faculty, and provides computer access for every faculty member. The comparative results would suggest that USC shares the number one challenge highlighted by the national participants, that “assisting faculty to integrate technology into instruction is the single most important Instructional Technology issue confronting their campuses over the next two to three years” (Kenneth Green, personal communication, November, 26, 2001).

It is in this context that the University received a $1.6 million Title III grant from the U.S. Department of Education to create the Instructional Technology Center (ITC)—a facility charged with faculty training in education technology methodologies. A major goal is to increase faculty use of educational technology for the purpose of enhancing student performance and academic success. To accomplish this goal, the grant enables the creation of an environment on campus where faculty leaders or “champions” are empowered—through training, release time, and access to current technology—to develop discipline-specific projects that will supplement traditional avenues of student learning through the appropriate use of educational technology. At the same time, these projects will serve as incentive models for other faculty members in their departments, colleges, and in the university at large. According to Horgan (1998), “Using faculty more proficient with the technology to support their less knowledgeable or more reluctant peers is another way to focus on teaching rather than just the technology. A faculty mentor program, with release time or other special incentives, is often an excellent way to jump-start innovation.”

As part of this mission, the ITC conducted a survey in the autumn of 2001 of representative faculty members from each department to establish a base of information on attitudes toward educational technology, current use patterns, philosophies of education related to computer-assisted education and factors affecting the adoption of technology by faculty members.

Theoretical Foundation

The adoption or “diffusion of innovation” curve developed by Rogers (1995) illustrates the way that an innovation is first adopted by a few members of a community, and how, over time, other members join in and begin to use or deploy the innovation. According to Rogers, an innovation is a concept or practice that is perceived as new by an individual, and diffusion is the process by which the innovation moves through the system. Members of a community who are more receptive to the innovation and who lead the other members are labeled “innovators” and “early adopters.” These are followed by the “early majority,” the “late majority” and, finally, the “laggards.”

One of the ways that innovation spreads through a community is via interpersonal communication and information sharing. Personal contact with an esteemed colleague, often including a personal demonstration, is key to the diffusion process in higher-education settings (Hutchinson & Huberman, 1993). Perceived leaders who adopt an innovation are particularly instrumental in the promotion of a new idea or practice. According to one study of mid-sized to large research universities, chemistry and mathematics professors favor different dissemination approaches depending on their current level of understanding and exposure (Foertsch, et. al., 1997). The same study, however, indicated that in most cases personal contact with an esteemed colleague was strongly preferred by the adoptee.

It has been posited that university faculty who fit the “innovator” model are self-motivated and, given the appropriate infrastructure, will integrate instructional technology even when incentives or rewards are absent (Jacobsen, 1998). With the sense that innovators are already “on board,” proponents of change have often focused on those in the early adopter and early majority categories because of a perception that they hold the most promise for advancement with the investment of the limited resources at hand. In contrast, those predisposed to the other end of the scale are oftentimes viewed as a poor investment in terms of the time and energy that is required to move them towards adoption.

Kurt Lewin’s (1951) “field theory” also provides a framework to analyze incentives (“driving forces”) and barriers (“restraining forces”) that faculty encounter. Identification of barriers to adoption is the first step in the process. Once barriers to change are identified, it is possible to remove the barriers or give the faculty the tools or resources that they need to overcome them.
Methodology

Full-time faculty from 24 campus departments were interviewed to elicit responses to closed and open-ended questions about their use of educational technology. For the purpose of this study, educational technology was defined as, “recent developments in computer-based technologies (hardware and software) used to facilitate learning.” The survey garnered responses from one representative within each department, with three exceptions where representatives could not be reached and did not return telephone calls or e-mail contacts. By interviewing a population of 24 (representing 11.8%) of the 204 full-time faculty, the researchers obtained a significant cross-section of opinion which is believed to be representative of general campus sentiment among faculty.

Results

Faculty interviewees were assigned a category of educational technology use based on their response to three questions. The first question asked them to self-evaluate their personal level of use on a five-part scale. The second question asked them to identify the educational technology that they used in their teaching. And the third question asked them the frequency of their use of educational technology. Based on their responses to these three questions each of the 24 respondents was assigned to one of three categories; below average (n=8), average (n=11), and above average (n=5).

Incentives

Next, respondents were asked to identify factors that convinced them to become (and remain) users of educational technology. Five choices were offered, along with the opportunity to name additional factors. The five choices were; personal satisfaction (selected by 58.3% of respondents), support from administration (selected by 16.6% of respondents), required by administration (selected by 4.2% of respondents), student demand (selected by 37.5% of respondents), and, because it’s the right thing to do (selected by 62.5% of respondents). Respondents were also asked to indicate which of the factors was the most important factor for them. The most common response was “because it’s the right thing to do” (n=6), followed by “student demand” (n=2). Other factors mentioned as being influential in adoption of the use of educational technology are:

- more student friendly*
- efficiency and efficient use of class time*
- convenience*
- good source of info and students have access to it*
- it raises student achievement*
- immediacy of communication*, sense of teamwork with students and between students
- I'm hoping that after I've been through it once, that my updating of material will be easier
- I think it's the right thing to do to familiarize students with resources
- richness and convenience of resources*
- kinds of material that can be accessed*
- found that students were gaining employable skills, need for visuals to provide relief...they are so visually oriented, students have to be at cutting edge of technology*
- students learn many different ways, and this type of technology allows you to use all three areas (visual, auditory, kinesthetic) and it enhances student learning*
- accommodating various student learning styles and achieving the desired learning outcome* I think it made me a better teacher.
- personal decision*

Note: * indicates factors that were considered to be the “most important” factor for the respondent’s choice to adopt educational technology

When considering the response to this question in relation to the faculty member’s designation as a below average, average, or above average user, it is interesting to note that, with one exception, the “below average”

[2] Multiple responses were allowed, resulting in total in excess of 100%.
users selected as their most important factor either “personal satisfaction” or another response that focused on student or instructor convenience. In contrast, all of the “above average” users selected either “because it’s the right thing to do” or a responses that focused on student outcomes, e.g., “it enhances student learning.” This sense of almost a moral obligation to provide the best possible experience for the learner is consistent with the belief that educational technology can accommodate a wider range of learning styles and can result in higher levels of student achievement.

**Barriers**

In an attempt to better understand what respondents perceived to be impediments to their adoption of educational technology, we asked them to list three barriers and the one that they considered the greatest barrier. Because of the wide range of responses, we attempted to group the responses into three main categories; time constraints, resource restraints, and questions about effectiveness. Responses that fit into the first category are:

- time to learn technology
- time to develop, time required
- too busy*
- planning time*
- time constraints on prep time*
- time constraints within class itself
- time to do it*
- because it wastes time
- time to experiment and discipline to learn the techniques that I don’t know*
- time to prepare*
- time it takes to find out what’s out there, find out what’s most effective and time to integrate it into what you do*

*Note: * indicates factors that were considered to be the “most important” barrier to adoption of educational technology

A sense that resources are not available to support development and implementation of educational technology is also an issue as indicated by the following responses:

- cost/availability of equipment
- resources
- lack of knowledge
- training/knowledge
- access*
- convenience of access*
- cost of purchase
- lack of hardware and facility*
- cost*
- funding
- lack of access
- shortage of classrooms that are equipped
- lack of help/facilitators
- money to purchase it*
- there was no one to provide assistance (when I got started)*

*Note: * indicates factors that were considered to be the “most important” barrier to adoption of educational technology

There continues to be concern that educational technology does not deliver on its promise or that its usefulness is still to be proven. The following statements reflect these views:

- doesn’t see how it always benefits students*
- not significant
- not so important to me…my current methods still work
- it doesn’t help*
part of the technology would be harmful to my pedagogy...some of the technologies out there, e.g.,
PowerPoint, are used poorly. Something is lost when you get away from FTF interaction
technology in general has not always been accommodating for people in the visual arts...a lot of the
technology is not image friendly*
• wondering if this is legitimate and achieving the desired outcomes
• not convinced of its usefulness*

Note: * indicates factors that were considered to be the “most important” barrier to adoption of educational technology

And finally, there are additional barriers that do not fit into the above categories. The following statements
reflect these concerns:

• apprehension
• doesn't always work
• comfort level*
• obsolescence
• difficulty of planning
• inertia
• difficulty of use
• copyright problems have created access problems

Note: * indicates factors that were considered to be the “most important” barrier to adoption of educational technology

Role Models

When faculty were asked if a mentor had used technology, and whether that experience had contributed to their
use of technology, those in the “below average use” group generally stated “no”, even if the mentor had used
technology. In the “average use” group, there was equal indication that mentors had or had not used technology.
Among the faculty who were mentored by technology users, more faculty indicated that they used technology
as a result, in part, of the mentor model. In the “high use” group, a majority of respondents enjoyed the tutelage
of mentor users, and indicated that this influence was a strong encouragement for them to model. Statements
regarding mentor influences included:

• everything I've done is because of my mentor...since he has left I've backed away from it somewhat
• my mentor created positive attitude toward technology
• positive modeling of use
• that particular person led me to make that a large part of my doctoral dissertation and although the technology
  has changed, it has had long lasting effects
• I had two wonderful mentors were I was before, and that's why I became interested in technology...it made
  all the difference for me

Other Influences

Faculty were queried on their observation of technology use in other venues, such as at conferences, and if that
experience affected their personal view and use of technology. All responders indicated that they had seen
technology, such as PowerPoint, employed. However, the “below average” and “average” user categories
indicated more reservations about the effectiveness of technology as it was experienced. More “below average”
users indicated complete dissatisfaction with the experience than did “average” users. Also, more “below
average” users indicated that they did not use this technology, or used it with reservations, than did “average”
users. In contrast to these two groups, the “above average” users unanimously indicated a positive experience,
and that the use had favorably impacted their own use of technology. Respondents offered the following
comments about viewing the use of technology by others, and its effectiveness:

• Sometimes it was good, but talking heads w/slides are also present so quality may be questionable
• it made me more committed not to use it
• limited helpfulness
• some are and some are not...I've really grown to dislike PowerPoint.
If person is not organized, presentation can reflect this
as long as the technology worked
inspired me
I've gotten ideas from people...usually through discussion groups or looking at their web sites
generally not...I've run into dull PowerPoint presentations
that is where I get ideas about what to try. I belong to the ASEE (American Society of Engineering
Educators) and they talk a lot about instructional topics

Faculty exposure to articles and on-line sources of information related to technology in education was also
explored. Faculty were asked if they had viewed such content, and if so, how had it influenced their use of
technology. Most respondents indicated that they had read about technology and issues related to its use, and
had found the information helpful. Most faculty responded favorably when asked about the positive model that
such material presented. Comments included:

I refer students to tech resources that I find
it opens up so many sources and resources for information, e.g., on the Internet
it puzzles me
it has made me see the value and importance of it
those discussions are ongoing in our field...effective vs. non-effective uses for my discipline. One thing that
you get from these public discussions is a sense of the value of the choices
provided ideas for newsletter, forms
hearing other faculty present ideas
distance learning techniques (Chronicle of Higher Ed)
it influenced me to a part that it has convinced me that it is a very important tool...even though I cannot keep
up with the innovation
reference again to papers at conferences. I like to see how others do things and then incorporate them in my
classes.
ganered some info, but not very persuasive
ideas on what it does and how it works
minimally, articles on teaching & pedagogy, not major input
journals like Syllabus and others give me ideas about hardware and ideas about use, e.g., using handheld
devices for education
not really
reading those sorts of things gives you an idea of what's going on in the rest of the country. Being involved in
TLTR, Steve Gilbert, etc. they encourage one to use technology when it is appropriate, because it will add
value if used appropriately.

Participants were also asked their opinion about the level of educational technology use and implementation on
the USC campus as compared to other institutions of comparable size and mission. There was clearly a
correlation between users' own use of educational technology and their perception of where the university in
general was in relation to peer institutions. Using a scale of 1-3, with 1 being "behind", 2 being "equal to", and
3 being "ahead", faculty members in the "below average" user group thought that USC was ahead of peer
institutions (mean = 2.67), while faculty in the "average" group thought that USC was "average" as compared
to similar institutions (mean = 1.94), and faculty in the "above average" user group believed USC to be behind
similar institutions in terms of use and implementation of educational technology.

Discussion

University faculty members enjoy a high degree of autonomy and self-determination. Change in behavior is
seldom achieved by the use of top-down approaches (Noblitt, 1997). Rather, change is usually the result of the
removal of barriers and the presence of incentives. Identification of barriers is one possible starting point for
adoption and diffusion research. Interviews with faculty leaders on our campus suggest that the leading barriers
to adoption of educational technology are; time, resources, and lack of confidence in the benefit of educational
technology. Our grant allows us to directly address the first barrier by providing 6 credit-hours of release time
and a summer stipend for faculty who successfully propose a project that uses educational technology to
enhance teaching and learning. The second barrier, perceived limitations of resources, is one that the University
has been addressing and continues to address using a variety of means. Campus computing infrastructure is currently being enhanced both in terms of functionality and performance. The decision to purchase Blackboard as our course management software has resulted in a growth from zero to 165 courses that utilize Blackboard in just the first year of use. A student-supported technology fee generates approximately $220,000 each year for technology infrastructure that directly affects students. All of these efforts are attempts to address concerns by faculty that their working environment is supportive of their efforts to acquire, create and deploy technology-enhanced resources. Perhaps the last barrier, faculty members' concerns about the effectiveness of educational technology, is the one area where much of the work remains to be done. This is an area where effective modeling by peers and respected colleagues shows promise for attitude changes that can lead to changes in behavior. Jacobsen (1998) found that faculty members prefer to receive help and instruction from colleagues on campus. While responses to our question suggests that demonstrations of successful use of educational technology by a respected peer early in one's career is a positive influence, it may also be that those who are early adopters of educational technology are more likely to recall such experiences. Other types of exposure to educational technology seem to send mixed messages. Exposure to use of educational technology in external settings and in academic and scholarly publications was as often as not seen as a disincentive. Dull or poorly executed PowerPoint-enhanced presentations were noted by several respondents. And finally, the presence of incentives for faculty to adopt and deploy educational technology is an area where both resources and faculty development play a role. As mentioned earlier, stipends are being offered to faculty whose projects are supported by the Instructional Technology Center on campus. Other faculty mentioned the convenience and efficiency that educational technology affords. But more often than not, the incentives that respondents mentioned were the benefits that they believed were accrued by their students. The belief that technology-enhanced instruction supported a wider variety of learning styles, and that students were learning both course content and picking up employable skills at the same time, were cited as incentives. While this study is exploratory in nature, it appears to support the idea that adoption of innovation, in this case the decision to employ educational technology, is multi-faceted and efforts to increase participation by faculty members must take an equally multi-faceted approach if it is to be successful.

Abstract: This paper describes AMANDA, a method for mediating asynchronous discussions among distant learners. AMANDA is intended to help tutors achieve better results from group discussions and improve knowledge transfer among the participants. The method consists of launching a set of issues for collective debate and involving the participants in successive discussion cycles with negligible human mediating effort. Along the discussion, specific mechanisms search for potential interactions that might improve the debate and propose new interactions among the group. This paper also presents the software prototype that implements the method, as well as some sample screens from tests carried out in actual training situations.

Introduction

Collaborative learning is about promoting knowledge transfer among the apprentices through a series of learning interactions. Among these learning interactions is the group discussion, a collective process of articulating knowledge by means of argumentative statements. Several works, such as (Quignard, 99) and (Veerman, 00) investigate the role of argumentative discussions in learning. In the knowledge creation theory by (Nonaka, 99), group discussions are characterized as externalization spaces, where the implicit knowledge (or mental models) of each participant is made explicit by means of the articulation of ideas. In traditional classrooms, such a dialoguing activity is achieved by face-to-face discussions and teamwork. In distance learning environments, asynchronous and collective discussions are implemented by discussion forums.

The experience with discussion forums, however, shows they often fail to promote group learning. They either suffer from the lack of participation or grow too much to be followed by the tutor. The reason is the absence of a method that articulates the discussion and promotes group interaction. In this paper, we propose a method and a system for mediating discussions among a group of distant learners with negligible or no interference of a human tutor.

Method Overview

The AMANDA method is a computational solution for mediating asynchronous collective discussions over multiple issues. Initially, a set of issues (questions) is distributed among the participants. The resulting answers give rise to successive discussion cycles, during which the participants argue over their peers' propositions. The collective discussion is mediated by a set of intelligent mechanisms that reason over the current discussion and propose new interactions among the group. The participants provide answers to the proposed questions and argue over their peer's propositions by means of discussion forms (Fig. 6).

AMANDA (Agent de Modélisation et Analyse de Discussions Argumentées) is a joint R&D effort between the Pontifical University of Paraná, Brazil (PUCPR), the Technology University of Compiègne (UTC) and CEGOS, France.
Internally, the interactions among the group are organized in a discussion tree (Fig. 1), a collection of questions, answers and argumentations representing the current state of the discussion. The mediating effort of AMANDA is focused on intentionally expanding the discussion tree with new nodes and thus creating new interactions among the group.

The Discussion Tree

The discussion tree is the underlying model of the discussion in AMANDA. It is an extension of the argumentation model proposed in (Karacapilidis, 98) and the Simari-Loui model presented in (Chesnèvar, 00). In AMANDA, the discussion tree represents multi-issue, multiparty argumentative discussions. It is composed of question nodes (Q-nodes), answer nodes (Alt-nodes) and argumentation nodes (Arg-nodes), as shown in figure 1.

A Q-node represents an issue to be debated. It contains a natural language question, such as "Which types of connection elements may exist in a computer network?". A Q-node can be classified as a content-expected interrogative speech act (Porayska-Pompa, 00), for which one expects an answer that conveys a certain "content" as response. In AMANDA, a question can be either typed by the tutor or automatically generated from the domain models. A Q-node can be linked to a number of answers, represented by the Alt-nodes.

An Alt-node is an alternative answer to a given question. The answer contained in an Alt-node is the "content" expected by its Q-node. In Karacapilidis' model, an Alt-node is a position over an issue. Every Alt-node is assigned to a given participant, who is the author of the answer. Formally, an Alt-node is a triple <a, Q, I>, where a is the textual content of the answer, Q is the related question and I is the author of the answer.

An Arg-node is a supporting/refuting reaction from a given participant over a position expressed by his peer. It conveys both an intention (supporting or refuting) and a proposition (a pro- or contra-argument). In fact, according to (Searle, 70), an argumentation is an illocutionary speech act composed of two elements: an essential content (intention to justify/refute a proposition) and a propositional content (the proposition that holds the intention). In AMANDA, the essential content is expressed in four levels: total agreement (Arg++), partial agreement (Arg+), partial disagreement (Arg-) and total disagreement (Arg-), while the propositional content is a free text provided by the participant. Every Arg-node is assigned to a participant, who is the author of the argumentation. Formally, and Arg-node is a 4-tuple <g, H, w, I>, where g is the propositional content, H is the corresponding parent node, w ∈ {++, +, -, -} is the essential content, and I is the author of the argumentation.

The Advance of the Discussion

AMANDA advances the discussion by expanding the discussion tree with new nodes, based on the current interactions among the participants. Figure 2a shows an overview of the proposed method. In stage 1 (Launching), the set of issues (Q) is distributed among the set of participants (P), which creates the first configuration of the discussion tree (DT) and the first generation of discussion forms (DF). In stage 2 (DF

2 Although the generation of natural language questions from domain models is an important feature of AMANDA, it will not be explored in further details, since it does not directly relate to the discussion mediation.
Reception), the discussion forms are received from the participants and the discussion tree is updated accordingly. In stage 3 (New Cycle), a new discussion cycle is opened, which corresponds to the aggregation of new nodes to the discussion tree and the generation of the corresponding discussion forms. New discussion cycles are successively opened until the discussion cannot be advanced any further.

Most of the reasoning employed in the method occurs in the New Cycle stage. The opening of a new discussion cycle occurs in five steps, as illustrated in figure 2b. It starts by filtering all nodes of the discussion tree that are not worth re-launching, i.e. nodes with empty textual content, highly supported nodes or nodes belonging to depth levels above a certain threshold. The Filtering step produces a set of re-launchable nodes (F).

In the next step (Extraction & Ordering), each node in F is assigned a re-launch score (RS). The RS reflects the importance of a node for the discussion, being expressed as the average among four attributes: (i) the agreement level of the node; (ii) the depth level of the node; (iii) the degree of support/refutation of the node in relation to its parent and (iv) the percentage of participants covered by the node. The higher the RS of a node, the more likely it is that this node will contribute to the advance of the discussion. The output of this step is an ordered list of nodes (O) sorted according to the RS values.

The Assignment step analyses each node in O to search for potential interactions that might advance the discussion. To handle this heuristic and multiple-criteria procedure, we propose the use of independent assignment mechanisms (AM), which attempt to find coherent matching relations between the set of nodes and the set of participants. Each mechanism applies its own assignment rules to find the most suitable participant to work on a given node of the discussion tree. If a given participant I is considered 'suitable' to work on a given node N ∈ O, then N is re-launched (an 'empty' child-node N' is created) and N' is assigned to I. The pair <N, I>, resulting from this matching, is called an assignment. Five assignment mechanisms are currently proposed (EXT, REPLY, BUDDY, EQUAL and VLD-ATCK), each one attempting to address specific objectives in the discussion.

The EXT mechanism proposes assignments to assure that all issues (Q-nodes) are answered by all the participants. The REPLY mechanism assures the right of response to every participant whose proposition was refuted in previous cycles. The BUDDY mechanism allows the participants to argue over answers on issues they have already answered. The EQUAL mechanism aims at spreading the participants over the discussion, so that every argumentation is equally argued among the group. Finally, the VLD-ATCK mechanism assures that all refuting argumentations are validated by the mediators/tutors (if any).

Each assignment mechanism proposes its own set of assignments. However, not all proposed assignments (PA) can be aggregated to the discussion tree. We must respect the maximum workload per participant and avoid undesirable assignments. This is done by the Assignment arbitration step, which filters the proposed assignments (PA) to produce the set of final assignments (FA).

![General flowchart and detailed flowchart of the New Cycle stage](image-url)
The assignments contained in FA are finally turned into new nodes and aggregated to the discussion tree by the Re-launch step. This is achieved by re-launching each assignment \( <N, I> \) in FA and assigning each new 'empty' node \( N' \) to the corresponding participant \( I \). In addition, the next generation of discussion forms (DF) is made available to the participants and the method goes back to stage 2 (DF Reception).

Method Implementation

The AMANDA method described above was implemented and tested in various training situations. The corresponding system (Fig. 3) is composed of a central Coordination Module that implements the flowchart of figure 2. The system has two user interfaces: a local interface that allows full control over the discussion and a learner interface that generates the discussion forms via the Internet. In addition, the system is provided with a Knowledge Base (KB) module that allows the construction of the domain models (ontologies and task models) and a natural language generator (NL Generator), which generates questions based on the domain models.

![Fig. 3: System overview](image)

System interfaces

The local interface (Fig. 4) enables all actions on the discussion, such as: creating a new discussion, adding participants/questions, viewing/editing the discussion tree, updating the discussion (DF Reception), inspecting parameters and opening discussion cycles. For research purposes, it also allows to simulate discussion scenarios with the aim of validating the method in a wide range of situations.

![Fig. 4: The local interface](image)
From the local interface, we can advance the discussion to the next cycle by clicking on the New cycle button. This calls the New Cycle interface (Fig. 5). On this interface, the assignment mechanisms can be individually triggered and the proposed assignments appear in the "To be assigned to" column beside the node to be re-launched. The Adjust button serves to filter undesirable assignments and to limit the number of assignments according to the maximum workload per participant (see Assignment arbitration). The Apply button finally opens the new cycle, by aggregating the new nodes to the discussion tree (Re-launch step).

Fig. 5: The New Cycle interface

As a new discussion cycle is opened, a new generation of discussion forms is made available to the participants. The discussion form for a given participant is built by grouping all 'just-relaunched' nodes assigned to him and formatting them appropriately, so that they can be answered and sent back to the system. Figure 6 shows a real discussion form in HTML format, as it appears through the Internet.

Fig. 6: The learner interface (HTML discussion forms)

The discussion forms are answered by the respective participants and are sent back to be processed by the system (DF Reception). The answers and argumentations contained in the discussion forms are used to fill the corresponding 'empty' nodes created by the latest re-launch and the discussion cycle is terminated. At this point, the re-launched nodes are grouped together in the discussion tree and the next cycle is started.
moment, a new cycle can be opened and new interactions among the group can be proposed based on the latest inputs from the participants.

Conclusion

In this paper we proposed a computational method for mediating group discussions, with the objective of relieving the tutor from the time-consuming task of articulating the discussion and improving the knowledge transfer among the group. This method was fully implemented and has been applied in actual distance training situations, where it has been the test-bed for various algorithms and coordination strategies.

The results obtained in the field so far are promising. They show that AMANDA enables to conduct collective discussions among large groups of participants over a large set of issues with negligible or no human interference. It is capable to autonomously articulate a discussion and find interesting patterns of interaction among the group. This yields in a ‘disciplined’ discussion, where the discussants are given equal chances to answer the issues, defend their refuted viewpoints and participate equally throughout the discussion. Another effect of this articulation is that the debate is progressively focused on polemical propositions rather than on common agreements, yielding in a better use of the effort employed by the participants and improving their motivation.

In addition to the discussion mediation, we also conducted experiences on domain modeling and NL generation. We've had surprisingly positive results on generating natural language questions from domain models (ontologies and task models) and using the resulting questions as discussion elements. We noticed that system-generated questions can be even ‘better’ than those proposed by human tutors, specially when the domain models are well constructed.

Although it is still unclear how well the proposed method performs in comparison with a discussion mediated by a human tutor, we have reasons to believe that AMANDA can be a valuable aid for distant learning and a start point for further research.

Developing a Large Web-Based Learning Environment – Can a Style Guide Help Learning Material Developers?

A. C. Elliott, N. A. Beacham and J. L. Alty

IMPACT Research Group, Department of Computer Science, Loughborough University, UK.

Abstract: An application specific style guide was produced for a large web-based multi-media and hyper-media learning project. It was introduced to 15 different sets of developers at Universities in disparate locations to promote consistency and good HCI practice for the whole project. This paper discusses the reactions to the use and practicality of the style guide through the findings of a survey undertaken one year later. In general, many negative and neutral attitudes towards the style guide were recorded. However, specific trends were observed due to exposure and use of the style guide, the background and experience of the developers and task involvement of developers. The paper discusses the understanding of HCI in the project and the need to encourage developers to use a style guide in multi-media and hypermedia learning projects.

Introduction

During the development of multi-media and hyper-media based learning material, there are often many Human-Computer Interaction (HCI) issues that arise. Developers therefore need to pay attention to good HCI practice when developing learning material. This is particularly important when an e-learning project is large and involves many developers, since it is often impractical for HCI checks to be made on every piece of learning material produced. One way to help achieve consistency in interface design is the use of a project-wide style guide. The use of a style guide can positively influence projects that are geographically dispersed, even, as in this case, when there is only a small group of Human Factors experts working on the software development project (Colbert, 1997).

Style guides, in one form or another, are used extensively in many industrial projects that use human-machine interfaces. They are also common place in many large web-site developments. However, the use of style guides in e-learning projects has not been widely documented. Universities and colleges often maintain a corporate style guide for their externally focused informational web sites, yet there are few examples of Higher Educational organisations using style guides during the design of user interfaces for computer-based learning materials. In places where they are used, it is normally in the form of look and feel or corporate guides, rather than helping the developer with task specific application style guides.

Much of the research in the area of styles guides that has been done to-date has been in commercial and industrial settings. There have been accounts from a number of authors on the benefits and problems of using style guides (Colbert, 1997; Hill, 1995; Kostelnick, 1998; Simpson, 1999; and Washington, 1993). The reported benefits of style guides are often more about the outcomes of applying good HCI practice, rather than empirically studying the implementation of the style guide. Those that have studied the development and use of style guides report that developers benefit from having more specific advice at hand (Simpson, 1999), that guidelines can be distributed quite cheaply and can be practical without the need for a HCI specialist and that user testing may not be necessary in aspects of the interface that are covered by the style guide (Hill, 1995). Accounts of specific problems with the implementation and use of style guides are more easy to pin-point. A re-occurring theme is that of the difficulty in managing the style guide. The process for managing the development, implementation, use and revision of a style guide is not well defined (Simpson, 1999). Washington has also reported that the “requirements analysis” and “promotion” of the style guide are often ignored or overlooked which often has detrimental affects. Hill identifies that guidelines can (1) be difficult to interpret; (2) often give contradictory advice and therefore need to be interpreted in context; and (3) often consider theoretical problems which, in practice, are not experienced often. Similarly, Kostelnick reported that developers can become frustrated deciding which style to adopt, particularly in the event that two or more styles conflict.
Use of a Style Guide in a Large Web-Based Educational Project

The authors of this paper were brought in to advise on the Human-Computer Interaction (HCI) issues of a large web-based educational project. It was decided to introduce a style guide that all learning material developers could use. The team began by performing a “requirements analysis”. A review was carried out of all fifteen University partners who were producing chemistry related distance learning material. As was expected, each partner was offering learning material in a format that they had developed independently. Therefore, inconsistencies existed in the whole look and feel of material, in the organisation of the content and in the way interaction between the learner and the information was initiated and completed. More importantly, there was an extensive amount of what could be deemed as “bad practice” being adopted across the University partners. Therefore, paramount was the construction of a style guide that would address the variations and contradictory signals being sent to the learner and to instill “good practice” principles in the developers. The purpose was to produce a style guide that would help application developers at the University partners - so that learners could concentrate upon learning the material, rather than wrestling with the interface.

Style Guide Development

A style guide should advise when and how to use controls and input methods and should encourage consistency and re-use within the aims of the project (Colbert, 1997). Therefore, the goal of our style guide was led by the need to provide clear direction on consistency and good practice during the development of learning material. This required guidance on application specific HCI design elements such as the design of interactive experiments, affordance and system navigation, as well as expected features such as text layout, design of primitive elements and the use of colour. In all, 44 separate elements that affect the interface design for websites were addressed. Particular features of the application style guide included:

- a section of readable prose explained why a style guide was necessary and how ensuring a similar look and feel throughout the project would be of help to the learner;
- individual recommendation sections on each of 44 different HCI design elements;
- a pull-out A3 size “pictorial reference” guide sheet at the back of the style guide that provided synopses of guidelines, with references to the main sections in the guide itself;
- full use of laser printed colour copying to offer the best clarity possible;
- softcopy production on CDROM in PDF format for convenience and accessibility.

In each of the 44 individual recommendations sections on design elements, the guide offered background information and a description of features, together with a diagram, and then outlined explicit recommendations or design guidance. The recommendations were tailored specifically towards the project and the use of the design elements for learning materials. Recommendations were provided on what developers should, and should not do with the item and indicated the degree of flexibility in the use of the item in the project. Following these recommendations, a set of examples was provided for each section of the style guide. These examples were screen-dumps of existing practice within the project or associated learning material and were accompanied by notes explaining any good points and possible usability issues.

The style guide was offered with the full backing and consent of the project management, the technical team and the educational content advisory group. It was introduced to the project partners and the learning material developers at a conference. The partners took hardcopy and softcopy guides away with them, in anticipation that they would be used in the further development of the learning material in the project.

Research into the Use of the Style Guide

During the following year, the use and influence of the style guide was noted whenever visits were made to developers. One project partner made full colour copies of the style guide for each member of the project team, which showed a commitment (at least in monetary terms) to the use of the guide. In other partner locations, the hardcopy of the guide was on the shelf of the project leader, apparently unused. Therefore, the authors of the application style guide sought to find out the usage of the guide, its practicality and any recommendations for improvements that could be made. At a conference, one year after the launch of the original guide, feedback forms were handed out to all conference attendees. The form included simple answer, Likert-based rating scales and detailed answer questions, on a two-sided sheet of A4. Responses were collected and collated. The remainder of this paper discusses the results obtained and the implications both for this specific project and also for others seeking to use a style guide in educational multimedia developments.
Investigation into the Effective Use of the Style Guide

Response Rate
The response rate of relevant conference participants was approximately one third (n=18). Of those who responded, 2 people had not had any exposure to the style guide and did not answer any specific rating-scale questions. A further 4 people only answered the first section of rating questions, relating to initial impressions but did not provide responses to their current attitudes towards the style guide. Therefore, only around 65% of respondents (n=12) fully answered all of the questions on the feedback questionnaire. Respondents comprised chemistry teachers (n=3, all completed all questions), other chemists (n=8, only 5 completed all questions) and computer scientists (n=7, only 4 completed all questions).

General Attitudes
One of the main findings from this feedback was that very few developers had truly used or referred to the style guide in the one year period. One third of respondents answered that they had only seen, but never used the style guide. The remaining two thirds had used the guide a few times during the course of the year but only two of these people said that they were currently using the style guide in their work.

Generally, trends were observed in the respondent’s use of the style guide and how positive their answers were. However, usage made no difference to the responses for some of the questions. In particular, most respondents provided negative feedback when asked if the guide offered them any new information or improved their knowledge of interface design issues. Feedback from the questionnaires also indicated a lack of understanding about the use of a style guide. Rating scale responses on initial impressions were mixed and included a lot of negative attitudes towards the style guide, even before it had been used. Free text answers from respondents suggested that they believed the style guide to be just something of interest, rather than to be actively used in day to day development of learning material. Many believed that the technical management group should sift through the recommendations and then present a standard set of icons and buttons and controls and should force all developers to do exactly the same thing with their material every time. Feedback also showed that they did not consider the style guide useful when it offered choice. In general, developers did not want general comments and ideas, they said that they wanted to be told what to do in each circumstance. They assumed that this would be the only way to provide the learner with a feeling of seamless interchange between the learning material in different modules, that had been developed by different partners in the consortium.

Respondents were asked about their attitudes towards each presentation idea used in the style guide. They were asked to rate the usefulness of the look and feel section, the detailed recommendations, the good and poor usability examples and the A3 pictorial reference guide. A nearly equal mix of positive, negative and neutral responses were recorded for every presentation idea except the use of examples, which had five times as many positive responses as negative ones. Free text answers also offered support for the use of good and poor usability examples and indicated that developers found these a good foundation for internal discussions, so that mistakes were not repeated in future. However, there was sense of egocentricity in responses. The project involved sixteen different partner groups developing learning material for a single learning environment, yet most respondents only wanted to see views on their part of the development. Respondents did not want to see examples of errors that others had made, indicating that the believed they would not learn from others mistakes.

Trends in Negative and Positive Attitudes Towards the Style Guide
Importantly, the exposure and use of the style guide appeared to be related to the attitudes offered in the responses to the rating scales. The most negative responses were from the one third of people who had not actually used the style guide. Most of those who had not used the style guide provided few responses to questions. Where there were responses from non-users, they were either negative opinions or indifferent attitudes. This was in contrast to those who had used the guide, who offered many positive responses. Also, the most positive responses came from the person who was currently using it in their day to day work.

Results showed some trends in attitudes for those with similar backgrounds. In particular, chemistry teachers offered the most negative responses. All chemistry teachers provided negative reactions to the use of the style guide in helping the development of learning materials, solutions to problems during development and the production of multi-media elements. They also said that it did not improve their knowledge of interface design or help improve the learning material that they were developing. In contrast, the computer scientists offered much more favourable responses. They were positive about the guide being clear, initially helpful and
still helpful one year on. They indicated that it was helpful in finding solutions to interface problems, helping develop learning materials generally, and was specifically helpful in the development of multi-media elements.

Responses were also considered in terms of the tasks that people performed and the computer packages they used during development. Trends in attitudes towards the helpfulness of the style guide were observed for these task groups. Figure 1 summarises each group’s attitude towards the 6 questions that were asked involving the helpfulness of the style guide during development.

![Bar chart showing attitudes of different task groups](image)

**Figure 1: the attitudes of different task groups in response to 6 questions on the helpfulness of the style guide in design and development.**

The first distinct task group were the “all-rounders” (n=6) who had very high involvement in the development of content and the design and who also used a number of packages including editors (HTML or other Web enabling package), graphics and animation or video packages. These were all chemists or chemistry teachers, with a mix of qualification levels. No particular pattern was observed in their exposure or use of the guide with some never having used it, some using it a few times during the year and one currently using it. This task group offered different opinions on their general attitudes about the clarity, usefulness and whether they were happy using the guide. However, they all provided similar, negative, attitudes towards the guide in terms of helpfulness in finding solutions to problems and developing learning material. The negative responses in figure 1 relate only to attitudes about the helpfulness of the style guide for design, development and review of resources.

The second task group were those who were “content driven” (n=4). These people were involved in the development of text, graphics and some animation or video work, but did not use as many packages as the “all-rounders”. They were all chemists and one was a teacher as well as a chemist. As seen in figure 1, the views of this group were less extreme, although generally not positive. This group also did not think that the style guide offered them any new information and did not improve their knowledge of interface design issues.

The third task group identified were the “technical designers” (n=3). These had no influence over the development of the content and therefore concentrated upon the design of text, graphics, animations and video using a number of appropriate computer packages. Again, there was a mix of exposure and use of the style guide in this group. Interestingly, this group provided mostly positive attitudes towards the style guide. They believed that the style guide was helpful in developing learning material and multimedia elements and helped them find solutions to interface design problems.

The fourth task group could be defined as “just doing” their job (n=3). Two of these group were computer scientists, the other was a chemist, all had lower level qualifications. They were not involved in the development of the content and were limited to the production of text and graphics. The only computer package used was an editor. This group offered more neutral responses than anything else – they were neither positive nor negative in their attitudes towards the usefulness, helpfulness and ease of use of the style guide.
Discussion

The negative and neutral attitudes recorded in the feedback questionnaire, together with a high non-response rate indicate that this group of learning material developers had many problems with the style guide. The lack of exposure and use of the style guide emerged as one possible reason for the unenthusiastic reaction. Indeed, initial impressions (before the guide had been used) were often not positive. Therefore, as a consequence of the original disapproving attitudes together with the style guide not being employed by the developers, the opinions one year on were understandably negative. The following discussion suggests three possible reasons why this situation occurred in this project. These are (1) the lack of understanding of HCI by the developers; (2) the workload and background of developers; and (3) the way that the style guide was managed in the project.

The Understanding of HCI in the Project

Responses to the free text questions in the feedback questionnaire gave the impression that there was a lack of understanding on how to use a style guide, and of HCI in general. Very few developers had come across a style guide before, which was reflected in their search for exact standards, rather than wanting a set of recommendations that they could apply in the right circumstances. Since a style guide should not de-skill the designers but should allow them to spend more time meeting their main objective of supporting user tasks (Browne, 1994) our guide was designed to offer some freedom to designers, whilst ensuring that they did not infringe any standard rules of good HCI practice. However, the developers on this project did not appear to understand this and often felt that there was too much information available. The comprehensive nature of our style guide may have, therefore, been an error, as producing unnecessarily complex style guides caused problems for developers in the past (Colbert, 1997). Yet, the production of detailed methodological guidance and compliance rules for a development environment for complex learning material is not easy. Therefore, providing more information, rather than less, and allowing designers the freedom to choose should still be considered, before offering a smaller sub-set of guidelines.

There was also a general attitude that most HCI information offered the developers nothing new. Most believed that they would not learn anything from the information contained in the style guide and that it was all “common sense”. Many thought that past experience as a teacher and personal “feelings” about the design would ensure that learning material would be correct for all learners. These attitudes reflect very little change in developers from those reported by other authors in the past towards acceptance of style guides (Lowgren and Lauren, 1993; Tetzlaff and Schwartz, 1990). These findings are particularly discouraging, since the style guide was introduced at a conference of the developers and also included a section explaining why consistency in the project and the use of a style guide was necessary. Perhaps the case for consistency to help convince the reader of the value of the style guide document (Browne, 1994) has not been presented fully enough in this project. In contrast, a particularly encouraging finding was the apparent relationship between exposure to the style guide and the positive feedback received, generally. Therefore, the conviction exists that if only developers could be encouraged to actually use the style guide, they would find it a more helpful document.

Workload and Background of Developers

The most positive responses came from those who only had a technical involvement with the project. These people were not involved in the production of the actual learning material content, but developed animations, graphics and text to support it. Therefore, task orientation may be a reason for the findings. It is possible that “technical designers” are happier using a style guide because they have a better understanding of the use of it, or have previous practice and education in using such materials. Also, they understood the computer packages used and had a better working knowledge of such applications, so they have more time to spend thinking about the design of the material. We recorded a number of feedback answers that implied that “all-rounders” and “content-driven” people felt that they had no time to look at the guide - taking a step back and learning about HCI design principles and their application was not a high priority for them. The design of the material was frequently viewed as one of the easiest parts of the project by teachers and, as such, developing the content took up most of their time and effort. Many “all-rounders” had to learn how to use the package as well as develop the content to the learning material, so time pressures may have meant that they ignored the style guide. Our results have shown a trend that indicates negative views of the style guide are held by those with many things to do in the development of multi-media and hyper-media educational resources, whereas those who have specific design problems have more positive attitudes towards the guide. This implies that more assistance is required to help every developer get the most out of a style guide.
Style Guide Management

The style guide was produced in hardcopy and in softcopy. However, there was little regular use of the style guide in any form. Unfortunately, each partner University was issued with only one hardcopy of the guide. In some cases there were up to 15 different developers working on the project at each partner University and visibility of the style guide was certainly less than we expected. In one partner University copies were produced for every developer but these were very expensive (136 pages, full colour). In most cases only the one hardcopy existed and this, more often than not, resided in one place with the team leader. PDF file format softcopies were not copied to everyone, or used as often as expected, even though the project was being produced on the computer network. We were not aware of these issues until our one year feedback questionnaire was collected and analysed. We expect different results if there were copies on every developers desk. Therefore, it is recommended that a follow-up on the use of the style guide and how well the information is being disseminated to all developers is examined in e-learning projects.

There is also one particular latent issue in the management of the entire project that seems to have had an adverse affect upon the use of the style guide. During the year, the technical management group implemented a cascading style sheet (CSS) to provide consistency in the colour, font size and style of the text in web (HTML) pages. The use of the CSS was simply to ensure that standard text was not formatted differently between different project partners. However, the partners saw the development and application of this style sheet as the answer to all of their interface consistency and re-use problems. It did, of course, help the layout of text but could not affect anything within graphics, animations or other applets placed outside of the standard HTML code. One year on, the pages look similar, but there are just as many HCI mistakes taking place in areas that are not formatted HTML text. The implications of the use of a CSS system for web design is that those who are not well informed on HCI issues may have their perceptions on the meaning of “look and feel” and “interface consistency” changed detrimentally.

Conclusions

The style guide produced specifically for this e-learning project was not well used by developers. Exposure to the style guide did prove to be a positive experience for those developers who tried to use it. However, many developers did not use the guide because their prior understanding of HCI issues, the use of a style guide and the meaning of “look and feel” did not encourage them. The background, workload and familiarity with the use of computer packages also affected their attitudes towards the potential helpfulness of the style guide. We have learned that in order to succeed, the implementation of a style guide needs to be closely managed and factors that affect the exposure and use of the style guide by the developers considered.

Abstract: This paper examines how teachers, as educational designers, can utilize universal design for learning (UDL) concepts. UDL is a comprehensive approach to the design of educational systems that addresses elements necessary for the achievement of desired educational goals and objectives: elements such as, equity among the participants, environmental supports, and the coupling between participant abilities and task requirements. The essential principles of UDL, which work synergistically, are: equitability, ergonomic soundness, perceptibility, cognitive soundness, error management, flexibility, and stability/predictability. The UDL principles presented in this paper draw from Enabling Technology Laboratory experiences as well as the knowledge and experience of many individuals, ranging from educators to engineers. Educational designers can systematically apply UDL principles to create more efficient and effective educational environments.

Introduction

Teachers commonly refer to their preparation work as “lesson plans”. Yet what they are really doing is design work: they are designing educational activities, materials, and curricula. Thus, teachers are educational designers. As such, educational designers have one simple goal: to create the best possible design. Universal design for learning is a conceptual approach that enables educational designers to more fully realize that goal.

Universal design for learning (UDL) is a comprehensive approach to the design of educational systems that addresses elements necessary for the achievement of desired educational goals and objectives: elements such as, equity among the participants, environmental supports, and the coupling between participant abilities and task requirements. The application of UDL principles targets the educational needs of all students while addressing different learning styles. Truly every student, from the gifted to the at-risk to the one with physical and cognitive disabilities, benefits from UDL. Technology plays a pivotal role in these endeavors by enabling increased adaptability and flexibility. The International Technology Education Association states that technology is “the diverse collection of processes and knowledge that people use to extend human abilities and to satisfy human needs and wants” (ITEA, 2002).

UDL builds on universal design principles developed by architects and engineers, but goes on to add principles gleaned from psychology and educational research. UDL strives to create environments, educational materials, and activities that are more physically and cognitively accessible. Physical accessibility includes wheelchair accessibility and computer access through the use of assistive technology such as alternative keyboards or screen readers. Perceptual accessibility includes dealing with disabilities such as color blindness, hearing loss, or visual impairments. While the distribution of IQs associated with cognitive disabilities must be considered, cognitive accessibility is not limited to individuals with disabilities. UDL must also include the creation of materials that support different learning styles and strengths, providing students with multiple ways of engaging the material, presenting material, and reporting results. In short, UDL should be regarded as simply good design practice.

The movement toward universal design has world-wide following. In the United States IDEA 97 (the 1997 amendments to the Individuals with Disabilities Education Act) is a major impetus for utilizing universal design principles in education, in that it mandates a fuller inclusion of individuals with disabilities in general education classrooms and activities. In a recent resolution the Council of Europe, Committee of Ministers, state the need to integrate people with disabilities into the community using universal design or “design for all” principles. Education was one of the specifically mentioned areas of need (Council of Europe, Committee of Ministers, 2001).

The European Concept for Accessibility Network makes the case for equating universal design with good design. In discussing diversity in the years 2000 and beyond they urge Europeans to “no longer talk about the specific needs of certain categories of people, but talk about human functioning. We should look at every aspect of
human functioning, without categorizing. ... Accessibility will lose its stigma and become a mainstream issue. We won’t need terms like Design for All or Universal Design anymore. We will only refer to good design and bad design” (European Concept for Accessibility Network, 2001).

The Enabling Technologies Laboratory (ETL) at Wayne State University embraces the definition of technology as “the diverse collection of processes and knowledge that people use to extend human abilities and to satisfy human needs and wants” (ITEA, 2002). This definition reinforces and supports the principles of universal design in that it allows technology to be not only devices, or things, but also processes, quality tools, and organizational/planning techniques. Through its partnership with eight southeastern Michigan Intermediate School Districts, ETL has worked with teachers to bring UDL applications into numerous classrooms. The UDL principles presented in this paper draw from ETL experiences as well as the knowledge and experience of many individuals, ranging from educators to engineers.

UDL Principles

The application of UDL should yield products and processes that are: equitable, ergonomically sound, perceptible, cognitively sound, error managed, flexible, and both stable and predictable.

Equitable: Educational products and processes should provide the same means of use for all users: identical whenever possible; equivalent when not. The products and processes should avoid segregating or stigmatizing any users, making the design appealing to all users (Connell, 1997). Figure 1 exemplifies this aspect of universal design. If a science classroom has binoculars available for field trips, then at least one of them should provide image stabilization.

Figure 1. An example of universal design. The binoculars contain microprocessor technology that stabilizes the image for all users. This allows a tired person or a person with tremors or other motor problems to use the same device.

Ergonomically Sound: The physical demands of educational activities must be within acceptable limits for a wide range of users. All individuals must be able to physically access the activity. Appropriate space for wheelchairs must be provided. The relative placement of materials, equipment, and users should be ergonomically sound. Students should be able to easily lift items, carry objects, turn knobs, press keys, and/or move computer mice; if they cannot easily perform such ergonomic tasks, alternative means of physical engagement must be available.

Perceptible: The product, system, and environment must effectively communicate necessary information to the user, regardless of ambient conditions or the user's sensory abilities (Connell, 1997). The design should utilize redundant modes of information presentation (e.g., verbal, iconic, pictorial, tactile). The design should maximize legibility by providing adequate contrast between the information and its surroundings. The expanded use of sound field systems exemplifies this principle. The teacher wears a cordless microphone and a portable amplifier/transmitter that transmits a signal to a receiver that then distributes the signal to speakers placed around the classroom. The sound field technology started in Special Education classes, but research shows that at any given time a high percentage of general education classroom students have hearing problems due to colds, flu, allergies, fatigue, and other temporary conditions (Crandell, Smaldino, & Flexor, 1999). Research also shows that students in sound field classes perform better academically than those not in such a class (Crandell et al., 1999). Hence, there is a growing trend to install sound field technology in all classrooms.
Cognitively Sound: The cognitive demands of educational activities must be within acceptable limits for a wide range of users. The task structure should be appropriate to the task — neither too wide nor too deep. The material must support different learning styles and human intelligences (Forrester, 2001).

Understanding the pivotal role of representations is central to the application of UDL principles. The educational material must provide different representations, which in turn appeal to different learning styles. Figure 2 shows a concept map illustrating habitats. This map was produced by a computer program that allows one to flip back and forth between a pictorial representation to a words-only outline form, thereby supporting different learning styles.

![Concept Map Illustrating Habitats](image)

Figure 2. An example of a concept map illustrating habitats. This conceptual map was produced using Inspiration® a software tool to help develop ideas and organize thinking. A menu option allows the user to express the map in an outline form — words rather than images.

Creating appropriate representations of thoughts and concepts is also critical for reflection and discovering higher-order relationships. The process of a learner reflecting and forming ever more complex mental models of reality is central to the constructivist's learning theory (Jonassen, Peck, & Wilson, 1999). Educational designers use the laws of calculus to formulate, simulate, model, and test hypotheses concerning the physical behavior of elements. The ability to represent physical concepts such as force and electrical activity with mathematics allows us to analyze systems and design products. Graphs, charts, flow-diagrams, cause-effect diagrams, affinity diagrams, and conceptual maps are also examples of representations.

The representation should facilitate, not hinder, the reflective process of the learner. For example, Figure 3 shows two ways of representing numerical density data. The shading represents the data. In Row 1 there is no correspondence between the numerical density data and the visual shading density. In Row 2 the shading deepens as the numbers increase; thus, there is a relationship between the shading and the data. Row 2's shading is more intuitive than Row 1's shading because the visual shading becomes denser as the numerical density data it represents increases (Norman, 1993). The representation in Row 1 forces one to think about and compare the visual shading to the numerical data values; there is no natural mapping between the two representations. If the educational objective is to analyze the data and draw inferences about some physical process, then the extra cognitive processing introduced by Row 1's encoding interferes with learning.

![Numerical Density Data Representations](image)

Figure 3. Example representations. The numbers represent some elements per unit area. Row 1's representation is less intuitive than Row 2's representation because in Row 2 the visual density increases as the numerical data density increases.
Flexible: The Center for Applied Special Technology (CAST) has formulated three principles that capture essential aspects of UDL in a simple and straightforward manner. Educators should provide students: 1) multiple means of representation, 2) multiple means of expression, and 3) multiple means of engagement (CAST, 1999). Multiple means of representing concepts, ideas, data, and information allow people with different learning styles or disabilities to more readily comprehend the essential concepts presented by the representations. Multiple means of expression provide people with a variety of ways to express themselves with respect to communicating, reporting, assessment, and evaluation. Lastly, and in some respects most importantly, multiple means of engagement enable people with different interests, learning styles, or disabilities to be more readily motivated to pursue and maintain engagement with the material. Motivation is a critical factor and, in that respect, providing multiple means of engagement is an essential element of UDL.

Flexibility is the key to providing multiple means of representation, expression, and engagement. Flexibility can be achieved in many ways across several dimensions. Table 1 presents five key dimensions of flexibility.

Figure 4 demonstrates flexibility; it shows a student in an adjustable, mobile, seating system. When the student was provided with this seating system, rather than her wheelchair, her teacher remarked that she “was now part of the class.” She could sit at the same tables, at the same height as her classmates. The student was excited and her classmates were also excited that she could now participate in classroom activities just as they could. (Also note that the seating system allows her to remain in her seating orthosis, which is critical for her ergonomic stability.) Thus, figure 4 exemplifies the UDL principal of flexibility because the special seating system enables this student to participate in “regular” classroom activities that were precluded when she is in her wheelchair.

Figure 4. Use of an agile device – a movable, adjustable chair made of Creform, a pipe and joint technology for creating agile devices. The student is out of her wheelchair and at the same level as her classmates, able to sit at the same tables.
**Error Managed:** Individuals learn by making mistakes; hence, UDL must manage errors. Educational activity associated with desired learning can be termed *value-added* activity. Activity not associated with the desired learning activity can be termed *non-value-added* activity. The non-value-added portions of the process must be error-proofed, while the value-added portion of the process must allow errors to occur (Erlandson, Greenwood, Perrin, & Zapinski, 1997). Figure 5 illustrates this idea for the educational objective of improving writing skills. The writing objective, inside the heavily outlined box, could just as easily be a computer program for mathematics or physics instruction.

**Retrieving & Delivering the Document**

- Physically get and deliver
- Email
- Fax

**Printing the Document**

- How is the print function invoked and executed?
- Cable / Infra Red / Wireless?

**Access to Printers**

- This is the value-added part of the process.

**Stable and Predictable:** Educational environments need to be stable and predictable in that the learners, teachers, and other participants can expect an environment that supports the desired learning. A school classroom requires an environment different from a field trip, or community based experience. A metal shop will have different requirements than a library. The desired educational objective dictates what is or is not acceptable.

While each environment presents unique requirements for stability and predictability, a common theme across all environments is the need to reduce the inherent variability of the educational processes or activities that take place in the environment. The inherent variability of an educational process is not to be confused with providing variation and variability of curriculum material activities. These are very different conditions.

The reduction of the inherent variability of a process is a fundamental principle of universal design and key to the creation of stable, predictable systems. Every task and process naturally has a certain amount of variability or variance. Deming termed this variability *common cause* (Deming, 1982). Everyday occurrences, such as traffic volume and the timing of traffic signals, contribute to the time variability associated with one’s drive to work. An accident or severe storm is an exceptional event that is not common to the process. Deming termed such events *special causes* (Deming, 1982). In terms of educational activities and the educational environment, educational designers need to plan for the occurrence of special cause events (fires, tornadoes), but they typically have no control over these special cause events. On the other hand, educational designers do have the ability to reduce common cause events and problems associated with such variability.

The task of balancing a broom on the open palm of one’s hand, broom bristles up, provides an example of common cause variability. The laws of physics introduce a great deal of variability and can make this task quite
difficult. An accomplished balancer has the expertise and skills necessary to balance the broom; however, most people would scurry around trying, with no avail, to keep the broom balanced. Most individuals simply do not possess the skills necessary to overcome the variation inherent to the process to successfully perform this job.

However, if the process is redefined by holding the broom in two hands, and introducing some technology, such as bracing the broom handle against a desktop, many more people can successfully perform the task. The redefined process and use of enabling technology, technology that enables improved performance, makes the task more accessible by reducing the variation inherent to the process. This illustrates a typical strategy for reducing the variability associated with processes: redefine the processes and incorporate enabling technology.

Workplace organization, standardized work procedures, and the use of visual controls all help reduce common cause variability. For example, the parking place lines and directional arrows present in parking structures organize the parking environment. As long as people understand and comply with these visual controls, the environment is largely self-managing. The knowledge built into the environment helps everyone perform correctly and allows optimal utilization of parking resources. The self-managing features of workplace organization, standardization, and visual controls built into the environment reduce the variability of human performance and create more stable, predictable environments for everyone (Erlandson, Noblet, & Phelps, 1998; Erlandson, 2001b; Erlandson et al., 1997).

Likewise, educational designers need to utilize design principles that reduce the common cause variability inherent in educational environments. Providing a safe, clean, and comfortable facility is an obvious and critical step. Creating a classroom flow that minimizes movement around the room and hence the opportunity for students to bump into each other and cause disciplinary problems is another technique for variation reduction.

Providing environments that are more self-managing is another step. Figure 6 shows a shadow diagram in a shop. This simple technology provides significant self-managing features as well as error-proofing. Everyone knows by looking at the board if a tool is present. Everyone knows to put the tools back over the corresponding shadow diagram.

Figure 6. A shadow board builds knowledge into the environment and creates a more self-managing environment.

Conclusions

The UDL principles of equitability, ergonomic soundness, perceptibility, cognitive soundness, error management, flexibility, and stability/predictability work synergistically. For example, Figure 7 shows three sets of dials. If the educational objective is to conduct an experiment wherein the dials (representing some part of the experimental setup) must be in the proper range for the experiment to proceed, then reading the dials is a non-value added activity not the essential learning objective. UDL principles would suggest use of the Level 4 arrangement. The experimenter can quickly see if the dial readings are appropriate. Not only are they within the marked area, but they are all vertical. This is a quick pattern recognizing cognitive operation, one that people are very good at. The Level 1 arrangement requires interpreting the three dial positions, a highly error prone operation with a large amount of inherent variability. The Level 3 arrangement is less error prone and possesses less inherent variability but still requires more cognitive effort than Level 4. In this example the visual controls build knowledge into the environment; thereby facilitating a more self-managing environment. Since the visual controls work for everyone, they are non-stigmatizing as they provide error proofing.

The systematic application of UDL principles creates educational environments that support competent participation by all students. UDL principles are good design principles that support a variety of learning theories. Educational designers can use the UDL principles to create more efficient and effective educational environments, curricula, materials, and activities (Erlandson, 2001a; Erlandson, 2001b).

An Exploration of the Potential of Causal Influence Diagrams for Assessing Progress of Learning in Complex Domains

Deniz Eseryel
Instructional Design, Development, & Evaluation
Syracuse University, USA
deseryel@mailbox.syr.edu

Abstract:
Despite the recent developments in the field of instructional design and technology, assessing learning complex domains remains quite challenging. This case study explores the potential of causal influence diagrams used by System Dynamicists for assessing the progress of learning in complex domains. The performance of eleven novice instructional designers is compared with the improvement in their causal influence diagram before and after the course. The results of this case study suggest that the evaluation methodology based on causal influence diagram is promising for assessing progress of learning in complex domains; however, more research is necessary to validate the methodology.

Introduction
An important yet little understood question remains as how to facilitate learning (and promote expertise) in complex domains (Spector & Andersen, 2000). Our knowledge about the facilitation of learning has significantly increased in the past two decades. Now, we know quite well how to facilitate learning in simple, well-defined domains. Unfortunately, we are not yet able to effectively facilitate learning in domains that possess highly interrelated dynamic variables and/or components.

A number of researchers propose different instructional approaches that may facilitate learning in complex, dynamic domains. Situated learning, cognitive apprenticeship, and cognitive flexibility theory are some of the perspectives that are being emphasized in this regard. On the other hand, some researchers also experiment with advance learning technologies hoping that they will uncover part of the mystery with learning and expertise in complex domains (Achtenhagen, 2000; Alessi, 2000; Spector, 2001). The biggest challenge in this line of inquiry is that a validated methodology for assessing learning in complex domains does not exist.

A review of System Dynamics literature suggests that causal influence diagrams (CID) is a very useful methodology to graphically represent complex, dynamic systems (Davidsen, 1996; Davidsen & Spector, 1997; Spector et al., 2001; Sterman, 1994). This paper presents the results of a case study, which explores the potential of causal influence diagrams for the purposes of assessing progress of learning in complex domains.

Method
A total of 11 graduate students at a large university in eastern United States, enrolled in introductory level instructional design theory and practice course participated in this study. Of these, 63% of the participants were female. All students were pursuing either a masters or a certificate degree in the field of education. None of the students had any prior professional or academic knowledge or experience in the domain of instructional design. Moreover, the students were not familiar with systems thinking, System Dynamics, or causal influence diagrams.

At the beginning of the course, the students’ learning preferences were assessed by VARK questionnaire developed by Fleming (2001). The results suggest that 63% of the students are not strong in visual cues. This means that they do not prefer the depiction of information in charts, graphs, flow charts, and all the symbolic arrows, circles, hierarchies and other devices for the purposes of learning or teaching. The rest of the students, as well as the instructor, were multimodal with varying degrees of preferences in all of the visual, oral, read/write, and kinesthetic modes.

To assess the degree to which participants would demonstrate an understanding of the complex problem domain, causal influence diagram was used. A causal influence diagram can be viewed as a kind of concept mapping technique tailored especially for dynamic and complex domains. It visually represents the dynamic influences and interrelationships that exist among a collection of variables. A causal influence diagram consists of a collection of nodes (key factors) and links. The nodes may be entities that can be counted, such as products or people, or they might be rates or processes that represent how things are changing. An annotated causal diagram has a description associated with each node to indicate the specific nature of that factor. The links connecting nodes are directional to show how one conceives of the causal relationship among the factors (e.g., a rate of change in weight might have a causal influence on blood pressure - the arrow in this case would point from rate-of-weight-change to rate-of-blood pressure-change). The links

Some System Dynamicists use the term "Causal Loop Diagram" instead of "Causal Influence Diagram". The author prefers to use the latter but also acknowledges that the two are synonymous.
are also annotated as either SAME (+) or OPPOSITE (-) to indicate whether a change in the causal factor tends to create a change in the same or opposite direction in the effected factor.

During the first week of the course, the students were asked to choose an instructional design problem in an area with which they are familiar and submit a short description of the context as well as the problem. Upon their submission of the problem description, they received feedback from the instructor and revised their initial description of the problem. Afterwards, the students were asked to draw out a causal influence diagram showing the relationships between the variables or concepts related to the problem of their choosing. After the students submitted their CID, they were asked to reflect on their experiences with this initial exercise in an online discussion forum. The students were also asked to post their CID in the forum and reflect on each other’s CIDs. Then, the instructor provided feedback to each student.

Throughout the course, the students were encouraged to practice with a number of different concept mapping techniques while working with the course materials and their course projects. After learning each instructional design step, the students submitted that part of their project assignment, received feedback and moved on to the next step. At the end of the course, the students were asked to submit the final version of the total instructional design solution for their project. Also, at the end of the course, they were given a different instructional design problem and were asked to draw a causal influence diagram for this problem domain.

Results and Discussion

After their first encounter with CID, the students reported the overwhelming feeling of confusion. They had problems while trying to represent the domain of their choice even though they felt they knew the domain very well. Also, some of them reported they were not used to represent their thinking in graphics; they were simply not visual. These students were not also familiar with any of the concept mapping methodologies.

While reviewing each other’s CID, the majority of the students thought their friends had done a fine job representing the domain (even though they were not good representations at all) so they assigned high grades to each other. However, as some students stated the reason of these high grades were not just for the work itself but also mainly due to the fact that they knew how much effort each put into that work. Most of the students also expressed their inability to judge the content of the diagrams.

The results were analyzed in terms of the improvement in their thinking on the instructional design problem. In general, their causal influence diagrams still lacked comprehensiveness but an overall improvement was noted. Afterwards, the students’ letter grades (which excluded CID exercises completely) were correlated with the improvement in their CID. The results suggest that causal influence diagrams do reflect the improvement in student learning. Students who showed improvement in the way they think about instructional design case as evidenced by their project work also showed improvement in their causal influence diagrams. However, one may argue a better system for comparison is needed in order to be able to better judge how novice CID compares to those of experts. Also, one may question the reasoning behind the letter grading during the course projects. Indeed, the grading method used was subjective although the instructor tried to be fair in her judgment. In fact, it is difficult to induce a more objective assessment tool to assess learning in the domain of instructional design due to its complex nature. In such complex domains, CID emerges as a very promising assessment tool of learning progress provided that it is further researched and validated in a variety of complex domains.

Digital literacy: A new terminology framework and its application to the design of meaningful technology-based learning environments

Yoram Eshet
Tel Hai Academic College
Tel Hai, Israel
eshet@nctvision.net.il

Abstract: Digital literacy is more than just using software. It includes reading instructions from graphical interfaces (photo-visual literacy), utilizing digital reproduction in learning (reproduction literacy), constructing knowledge from non-linear navigation (lateral literacy), and evaluating information (information literacy). These literacies serve as a measure of the learners’ work quality in digital environments. The present paper proposes a terminology framework for digital literacy. Discussion of every literacy type is accompanied by results from a study that examined the ability of learners to effectively utilize digital literacy in educational contexts.

Introduction

The fast developments in digital technologies during the last decades confront members of the technological society with situations that require the utilization of an ever growing assortment of cognitive skills, termed ‘digital skills’. Examples that are commonly given to these skills include the ability to access or retrieve data, to use computer programs, and to operate digital appliances. Using digital skills require the users to own a relatively new kind of literacy, termed ‘digital literacy’ (Lanham, 1995; Pool, 1997; Inoue, Naito and Koshizuka, 1997). However, digital literacy is much more than just the physical proficiency in operating computer programs, as many studies describe. It is a special kind of mindset; a special kind of thinking. For example: using a computer program involves the user’s ability to communicate by deciphering, or ‘reading’ messages embedded in its interface. It also involves retrieving data from the Web, which requires the user’s knowledge, not only of how to use search engines, but mainly of how to evaluate the retrieved data and distinguish between its relevance and non-relevance. It also requires a smart use of the hypermedia technology that involves lateral-associative thinking, which is very different from the traditional, linear reading of a book. The digital reproduction (copy and paste) capability of computers face learners with new horizons and offers a new meaning to creativity and ingenuity. All the above require the utilization of a new, very elaborate and flexible way of thinking, that is typical of digitally literate learners.

This paper proposes a terminology framework, and describes the major dimensions of digital literacy. It presents some research findings on the utilization of these types of literacy among youth and adult learners.

Methodology

In order to investigate the various aspects of digital literacy, three groups of participants were selected. The three groups were:
- 10 high-school students (age 14-15)
- 10 college students (age 24-28)
- 10 adults (age 30-40)

All participants were given assignments that required performing the ability to use different kinds of digital literacy: each assignment designed to address a different literacy. Details on each assignment are given below. The participants worked on the assignments individually. Each age-group worked separately, but at the same time. The assignments required the participants to perform work with computer programs. The participants were observed as they worked on the assignments, and notes were taken regarding the nature of their work while performing the tasks. The outcomes of the assignments, as well as the documentation of the processes of each participant’s work, were used to assess and comment on their digital literacy. At the moment, the research findings are not yet completely analyzed, and, therefore, only the clearest and most prominent results are presented. For the sake of coherence, in the paper, every dimension of digital literacy is presented separately, and
then discussed with respect to the relevant research findings, that are used to elaborate on its educational significance and utilization.

Photo-Visual literacy - Learning to read from pictures

Writing is a means of communication using symbols. It has evolved through history from a pictorial alphabet, that used meaningful symbols to represent words or letters, and therefore required a low level of cognitive mediation, to an abstract alphabet that uses "meaningless" symbols (letters) and therefore requires a higher level of cognitive mediation. The evolution of computer interfaces show a reciprocal trend, evolving from non-interactive, text-based, hard-to-learn batch interfaces, into intuitive picture-based, easy-to-learn Graphic User Interfaces (Nielsen, 1993). The first interfaces (either in CPM or in DOS operating systems) were operated by text-based commands and required a very high cognitive mediation on the user's side (e.g. memorizing commands and understanding commands' syntax). In the 90's, under Windows environments, interfaces evolved into the icon graphic-based, highly-interactive Graphic User Interfaces, that are highly-intuitive and easy to learn. They appeal to the user's intuition and do not require a high cognitive mediation (Shneiderman, 1998). The evolution of interfaces marks three major trends: (1) an increase in the level of visualisation, (2) an increase in the level of interactivity, and (3) a decrease in the level of cognitive mediation required to reach proficiency in the use of the interface. Since computer interfaces communicate between the user and the program as they contain the information necessary to operate the program, using an interface should be regarded as a reading skill (Mullet and Sano, 1995). Therefore, the evolution of interfaces can be regarded as an evolution of a new kind of writing, from abstract text-based to concrete icon-based communication. We suggest that in order to perform well with this new means of communication, one must have a good command of a unique form of digital literacy – the 'photo-visual literacy' - that the graphic interfaces have brought about: a literacy that requires the ability to use visuals (icons) as messages or "text", as described by Snyder (1999).

In order to examine how different users cope with different types of interfaces, we ran a usability test of two programs that share the same major objective (to design a stage), but are designed under a completely different approach: One (Stage Struck) has a pure graphical interface: almost no menus and no 'formal', predefined target. It is the user's responsibility to find out how and what should be done in the program. The other program (The Opening Night) has a very structured and quite 'expected' design (though it is also graphic). It is menu-driven; menus are textual; the user's task is well explained and determined in a text form.

The present research results show that the Adults group performed better with the more traditional interface of Opening Night, whereas the youngest participants performed better with the highly intuitive and graphic interface of Stage Struck. In addition, the research participants included three dyslexic persons, who were not fluent readers of a regular text. It was interesting to find that they scored among the highest with the graphic interface of Stage Struck, but were very unsuccessful with the traditional, more text-based interface of The Opening Night.

Our research has pointed to another aspect of photo-visual literacy that involves the way young children learn to read a new language. During interviews with the research participants, we came across, and documented two cases of 4-5 year old children (Chilian and Israeli) who learned to read and speak some basics of a foreign language (English) from ‘living books’ types of programs such as Just Grandma and Me (http://www.thereviewzone.com/grandmame.html). In these programs, the text is highlighted phrase by phrase, simultaneously with the narration. From discussions with the children, and then with their parents, we discovered that these children were able to pick up the words, and to formulate preliminary spoken sentences that are beyond the sentences read to them in the program. In doing so, they were tracking the highlighted words, and combined the visual shape of each word with its narration. This case seems to suggest another kind of digital literacy, that enables learning new languages through perceiving words as 'pictures', rather then a combination of letters, and by synthesizing audiovisual stimuli (Beavis, 1999).
Reproduction literacy: The copy and paste culture - a new interpretation of creativity and ingenuity

The invention of the press by Gutenberg (1455) marked the first big leap in the ability of humans to copy, reproduce and distribute information on a large scale. The second big leap was made possible by the digital reproduction capabilities (e.g. the Copy and Paste feature) of computers, that enabled people to reproduce or edit digital texts or visuals. (Benjamin, 1994). The unlimited possibilities to reproduce and distribute digital information led to new interpretations of originality, creativity and ingenuity of artwork as well as of academic text. These interpretations ask questions such as “How far can one copy or edit artwork or text, so that it is still considered an original work and not plagiarism?” “What are the limits of creativity? When does it become a technical act of reproduction?” A classical case that pushed the limits of meaning ful art in the reproduction era was the case of Drako Maver (1998) (http://www.kapelica.org/maver/main.htm). Maver was a non-existent person who was invented as an Internet artist, and whose works were a collage of pictures of corpses copied from the Web and edited. This faked artist was invented and introduced by a group of Italian students as part of a large-scale effort to challenge the limits of art in the reproduction era. So successful was this effort that Maver even won some prestigious awards for his pioneering Internet art works... (of course, the referees were not aware of his non existent nature). Can these works be considered art, real, original, and creative? Coping with this challenge requires a special kind of digital literacy on the side of the digitally-literate user. We tentatively term this literacy ‘Reproduction Literacy’.

In the present study, we investigated people’s attitude towards reproduction literacy in two ways: (1) by presenting them with the the Maver case and asking whether they would consider it art work and (2) by giving them a digital essay, asking them to edit it (rearrange words; add/delete text), so that it can be used in a completely different context. Results clearly show the attitude differences between younger and older people. The recognition of Maver’s work as a legitimate authentic artwork decreased from 75% among the youngest group (high-school students) to 39% among the college students, and to only 13% by the adult group. The opposite was found for the second task, that required participants to reuse text in order to create something original. Here, the adult group performed the best (43% of them succeeded in fulfilling the task). Success dropped to 35% with the college students, and to only 19% by the high-school students. This finding, of decreasing success from older to younger learners, conforms with reports of Labbo, Reinking and McKenna (1998), that described problems of treating digital text by young students compared with that of adults.

Lateral literacy: Hypermedia and thinking

Besides improving people’s performance with computer programs, the hypermedia technology introduced computer users with new dimensions of thinking and new challenges of digital literacy, that are necessary in order to make an educated use of this elaborate technology. In the past, the limited non-hypermedia-based computer environments enhanced a more linear thinking that was dictated by the the non-flexible operating systems, and the fact that users were used to books, and expected to work with computer-based environments in the same way they read through books. From an educational perspective, the major importance of the hypermedia-based environments is not so much the multi-tasking work they allow the user, but the ability to use these environments for navigating laterally, in a non-linear way, through knowledge domains. This capability enhances a lateral, multi-dimensional thinking, and has led to the evolution of a new kind of digital literacy – ‘lateral literacy’. Rouet and Levonen (1996) discussed the impact of the hypermedia technology on learning. They suggested that this technology helps learners to move away from linear thinking into a rich-associative lateral thinking. According to them, in order to perform demanding multi-level tasks, learners must be able to think laterally and synthesize knowledge from pieces of information that are collected in different, sometimes independent, domains of knowledge. Spiro, Feltovich, Jacobson, and Coulson. (1991) discussed the role of hypermedia in forming a multi-dimensional knowledge, based on flexible cognition. Some authors (e.g. Salomon, 1996) raised doubts as to the ability of learners to form meaningful knowledge by surfing in hypermedia environments as the Internet.

In order to examine the level of lateral literacy among learners, the participants of our research were asked to perform a similar task: To plan a trip in a foreign country by using information from the Internet. This task requires the learners to utilize lateral literacy in order to combine independent pieces of information (collected by laterally surfing in the Internet), in order to construct knowledge (the trip). Although analysis of results is not yet completed, findings seem to point to the high ability of the youngest participants (high-school students) to perform the task. The weakest performers were the adults, who tended to stick to linear surfing, that is, they made very limited use of the hypermedia technology, which led to a very poor outcome (a plan of a trip...
to a foreign country). These findings probably reflect the extensive exposure of young people to hypermedia environments. It may suggest that the exposure of learners to rigid, linear learning methods harm their cognitive flexibility, and affect their ability to cope with ill-structured problems (Spiro et al., 1991). On the other hand, the research findings may indicate that the extensive exposure of young students to the lateral, non-linear surfing on the Web, improved their ability to utilize multi-level constructivistic cognitive skills.

**Information literacy: Trust nobody**

Today, with the exponential growth of available information, the consumers' ability to evaluate and assess information has become a key issue in training people to become educated consumers of information (Kerka, 1999; Salomon, 2000). Information can be be classified into the following general groups: (1) primary objective information (e.g., all kinds of census data, migration routes of birds, distribution of volcanoes, satellite images, and weather information). It is usually easy to assess the validity of this information; it is original and relatively unbiased. (2) primary subjective information (e.g., much of the news in newspapers and diaries). These are usually biased to some extent, and it is usually hard to assess the quality and validity of this type of information because the average consumer is not fully aware of the fact that the term 'truth' is very subjective, and that even 'objective' information (what people call 'fact') can be easily treated in a biased way to produce a very subjective piece of information. (3) synthetical information (e.g., journalist articles, scientific hypotheses and models). This type of information is usually professional, more mature in its nature, and usually attracts relatively educated, sometimes professional, consumers, who are capable of assessing the quality of information properly.

We suggest that the ability of information consumers to make educated, smart, information assessments requires a special kind of literacy, termed here 'Information Literacy'. This literacy acts as a filter: it identifies false, irrelevant, or biased information, and avoids its penetration into the learner's cognition (Minkel, 2000). It is true that information literacy is not unique to the digital age only. It was always a crucial trait of successful scholars, even before the information revolution of the digital age. But in the digital age, with the unlimited exposure of humans to digital information, this has become a crucial prerequisite that enables learners to make an educated use of digital information. Without a good command of information literacy, how can one decide which of the endless pieces of contradicting information found on the Web, to believe? Which of the news on the Web to trust? Which political opinion posted on the Web to adopt?

In the present research we examined information literacy. All participants were asked to access seven different Internet sites that contain Middle East news (the Internet site of a main-stream Israeli newspaper; a terrorist organization information Internet site; a site of an Israeli government news agency; two private, politically-oriented news sites; an Arab country news site, and a site of a European news agency). Participants were given several events (news) that were reported in all of the examined sites. They were asked to assess and rate the quality and objectivity of the news. Analysis of results is yet incomplete, but one trend is evident: The younger the participants, the lower their information literacy. In other words, the oldest participants showed a significantly higher ability (49%) to apply critical thinking to information, compared to the youngest participants (15%). These findings, especially in the light of the fact that youngsters are among the most extensive consumers of digital information (in the Internet or in other forms of digital information and communication), illustrate the critical importance of emphasizing the inclusion of teaching information literacy in education systems. The low 49% for adults is also very worrying. It doubly suggests that information literacy be taught in schools.

**Conclusions**

This paper presents various aspects of digital literacy that are usually neglected in educational research concerning the impact of digital information on our society in general, and our education systems in particular. It proposes a terminology framework for digital literacy, i.e. photo-visual literacy, lateral literacy, reproduction literacy, and information literacy. The following (preliminary) research results were found for each type of literacy:

- The youngest participants (14-15 years old) were the best utilizers of photo-visual literacy; they were capable of working very well with graphic interfaces while the older participants were better with more traditional, menu-driven, or text-based interfaces.
- The dyslexic participants performed better with graphic interfaces, then with traditional, more text-based ones.
- The older participants were the most reproduction-literate learners; they were best in rearranging or reusing prior information into new forms of knowledge. On the other hand,
the youngest (14-15 years old) participants were more flexible in their perception of the originality and ingenuity of works made using digital reproduction methods (albeit a sophisticated 'copy and paste').' The youngest participants (high-school students) showed the highest level of lateral literacy, which seemed to decrease with the older age groups. This finding is probably strongly related to the extensive exposure of youngsters to the hypermedia environments of the Internet. The oldest participants in the research (>30 years old) had the highest level of information literacy, whereas the younger participants were not overly capable of making good evaluations and assessments of information. This finding illustrates the importance of emphasizing teaching critical information literacy in educational systems, especially in schools.

In general, two, different, modes of approaching digital literacy were evident among the research participants: The technological mode (using modern graphic interfaces; surfing the Web in non-linear ways), and the pedagogical mode (creating meaningful digital reproductions of knowledge; critically evaluating information). The younger participants were better performing technological tasks whereas the older participants performed better in pedagogical tasks.

More research and data analysis are required in order to examine the validity and applicability of our findings in wider populations.

United States

Abstract: Now that online distance education has outgrown its infancy, increasing attention is being paid to evaluating online course offerings. A stable, easy-to-use web-based course evaluation system is a necessary part of any distance education evaluation effort. This presentation describes the design, development, implementation and revision of a worldwide-web-based system for creating and administering student evaluations of online distance education courses and on-campus courses utilizing Internet technology. The system was developed after assessing instructor needs for such a system and reviewing the existing and potential options for meeting those needs. The system was designed to provide for both traditional summative (end-of-term) evaluation and mid-semester formative evaluation.

Introduction

With the incredible growth of online distance education over the past decade, with over 1.5 million students earning college credit online in the 1997-1998 school year, according to a National Center for Education Statistics (NCES) study, and 82% of the institutions in the NCES study planning to start or increase their online offerings, and the need for faculty and administrators to evaluate these new courses and degree programs, it is essential that tools designed expressly for collecting student feedback to this new type of college course are created. This presentation describes how the instructional support office staff at a large midwestern state university's School of Education designed and developed (with faculty input) an online course evaluation system called EvalOnline. The system can viewed online at http://ic.educ.indiana.edu.

Overview of the Project

In our presentation, we will:

- Share the results of our faculty needs analysis regarding their requirements for an online course evaluation system.
- Provide a technical overview of the system, and the related decisions made.
- Describe how the system is currently being used.
- Describe our plans for further development of the system.
Needs Analysis

The EvalOnline system was created in response to feedback from our faculty and associate instructor clients about their dissatisfaction with the university’s existing online course evaluation system and how it failed to meet their needs as distance educators. In a series of informal discussions and during one-to-one consultations with them, we discovered the following instructor needs:

- Accessibility and Ease of Use for Students
- Ease of Use for Instructors
- Compatibility with Existing School Requirements
- Flexibility
- Relational Database Capabilities

Technical Overview

In the initial stage of the development of EvalOnline system, the design team researched the benefits and disadvantages of using a Microsoft Windows-based server compared with the Linux/Unix-based server alternative. Once the platform was chosen, the design team started work on the database infrastructure and the web interface with which the users would interact. Instructors and students were both given the same web address to access the system (http://ic.educ.indiana.edu). On that page, they saw buttons for Students, Faculty and Administrators. Students clicked on the Students button, and then were shown a page that allowed them to login, using the password given to them by their instructor. The next page shown to them was the course evaluation, which incorporated both Likert Scale (Strongly Disagree to Strongly Agree) and open-ended questions (more question types will be added soon). They chose their responses and then clicked the Submit button, which added their course evaluation information to the system. For instructors, the system allowed for a wider variety of activities: they could create or edit their account, create or edit a course evaluation, or view the results of their course evaluations. Administrators (departmental secretaries, primarily) could view course evaluations of their instructors.

Current Use

During the Spring 2001 semester, the first semester of wide (post-pilot) availability, 50% of the instructors teaching online courses for the School of Education utilized the EvalOnline service to create and deliver their end-of-term course evaluations. The rest of the online instructors either used the previously existing university testing/grading system or did not administer a course evaluation to their students. We hope to increase this percentage by describing and demonstrating the use of the system to the rest of the instructors. We also expect that the faster system response time allowed by the new 900mhz Pentium III server and the greater ease-of-use due to interface and documentation refinements will increase instructor acceptance of the system. As the School’s distance education program continues to grow, adding additional courses and programs, we expect use of the system to continue to rise. We have also had several on-campus instructors utilize the system and we expect this type of use to rise as well.

Future Development

In the near future, we plan to survey a sample of the students and instructors who utilized EvalOnline during Fall 2001 and Spring 2002, to get their feedback regarding the system’s strengths and weaknesses. After analyzing the responses, we plan to initiate a new round of revisions and refinements to the program. We are also planning extensive changes to the administrative interface, to allow administrators to save and print more advanced reports, and to make general administrative features easier and more time-efficient.

On-line Net.art Gallery and Educational Resource

With the guidance of Professor Mark Amerika, a group of students within the CU Boulder Fine Arts Department have completed an on-line art gallery entitled Histories of Internet Art: Fictions and Factions. This gallery features Internationally acclaimed works of Internet art, hot new works by up and coming net artists, as well as the best student efforts coming out of the CU Boulder Techne Lab. Nearly all of these pieces are complemented by student written reviews, which serve to help clarify many of the new concepts presented by contemporary artists. In conjunction with the visiting artist program at CU, prominent net artists have been invited toCU to be interviewed and lead workshops with students who are participating in this program. Interview text and clips as well as art generated from these sessions are also presented in this gallery. In addition, there is an area for researched net theory and links to other collections of net.art.

My proposal is to present this gallery to the participants of the ED-Media Conference and give a short lecture and demonstration of what can be found within this gallery and how it can serve as an essential tool for University art departments that are interested in exploring this new art form. Art departments across the country will likely be including this site in their digital arts research list. Although official press releases have only begun to be circulated, there has already been international attention from The Whitney Biennial, Alt-X, Naural.it, and others.

One of the most significant aspects of this gallery is that it is student created and maintained and will continue to grow and offer important original content. Of much interest to the art community and art enthusiasts in general is the filtration of the artwork and the resource created by bringing these works to a central location. The interviews are also extremely popular as they are original content that can only be found on this site. As an educational resource, students can view and explore this artwork as well as study some of the essential theory that has influenced this art movement. The reviews are also helpful in determining which pieces are important topics of research and many suggestions and points of view are offered as to the significance of these works. Faculty and staff in academic art departments who are interested in starting or enhancing a digital arts program can look to this as a resource and a link to pertinent information.

Although net.art is still fairly new in the art scene, it has made its way into mainstream acceptance and there are on-line galleries now being offered by the Whitney, The Tate, SFMOMA, and many other prestigious institutions. Net.art may be the only art movement that has gained this much acceptance in such a short time ever before in the history of art, much being owed to the accessibility of the medium in which it resides. Because this medium is such an open and leveling platform, the history of Internet art is being written and argued by prominent artists, critics, and art historians simultaneously while the movement is gaining popularity. It has been accepted that anyone can publish their findings and opinions on the Internet and although this creates a means of having a voice for all individuals, the question arises as to who will actually look at what has been published. This has created a new form of economy: the attention economy. The attention economy is already a formidable force and may yet become one of the most influential economies yet. As any advertiser well knows, the attention economy has a direct bearing on its monetary counterpart as it is only by gaining the attention and trust of a consumer that a product can sell. Everything on the Internet is clamoring for the
attention of the surfing audience, and there is a great need for a trusted filtration mechanism to highlight some of the more important information. The Histories of Internet art gallery hopes to become a popular filter and an important hub for linking to the best that the International community of net.artists has to offer. In also having a section for student works, it is possible for students to gain the attention from the art community while attending school. This type of design can also serve as a working template for other student-run on-line galleries.

Many argue that Internet art is only a combination of audio, video, and text based art forms. There is a new aesthetic that is emerging from the blend of these mediums combined with interactivity and the network space. It is possible to use the rest of the Internet as a dynamic entity within this new form of art. Interactive elements blur the divisions between artist, viewer, critic, theorist, and historian. Commercial development of web based tools and software is fueling this new form of visual creative expression, and it is important to demonstrate that there are alternative ways of viewing the Internet as a medium. The Internet can be seen as a digital canvas that has tremendous accessibility potential. It does away with issues pertaining to physical space, transportation, collections, and formation of an established canon by the powers that be. There has been much theorizing as to how this affects present culture and how it will influence art movements in the future. It is of great importance to illuminate and explore these implications as they cannot help but influence all forms of art. Even the most traditional artisans are turning to digital aids to more efficiently produce and manipulate their work. Not only does this create new possibilities in imaging but also a new aesthetic sensibility has emerged as a by-product. It is critical that this is not overlooked.

In the short span of the lecture I wish to present, I plan to raise some of these issues in relation to the on-line gallery that we have created here at the University of Colorado at Boulder. Histories of Internet Art: Fictions and Factions gallery (http://blurr2.colorado.edu/~hiaff) is being developed as part of the TECHNE practice-based research initiative with the support of the University of Colorado at Boulder Department of Fine Art, the blurr_lab, and ATLAS (a campus-wide technology initiative). From its initial inception, it has brought together talent from the college of Fine arts, Journalism, and Engineering. It is my hope and intention that other disciplines within academia will become interested in participating in and embracing this method of on-line presentation and this new field of creative expression and communication. It is also my hope that I can generate interest and stir excitement in this new form of fine art. Thank you for your consideration.
Technology in a Constructivist Classroom

Donna Ferguson Pabst, Ph.D.
Department of Educational Technology
University of Northern Colorado

Introduction
Here is Edward Bear, coming downstairs now, bump, bump, bump, on the back of his head behind Christopher Robin. It is, as far as he knows, the only way of coming downstairs, but sometimes he feels there really is another way, if only he could stop bumping for a moment and think of it. Milne, 1996

The quote from Milne speaks to the way many teachers function in the K12 arena. There is so much to do and so little time to do it in, they continue to do work in the same way it has been done for decades. Teachers generally know there may be better methods available, but do not have the time to investigate what they are. As assessments and data-driven instruction become increasingly important, teachers must stop "bumping" down the stairs in order to become more efficient, effective users of the equipment provided for them. Integrating technology into a Constructivist learning environment is one way that is currently being advocated as a method that will move more students toward functioning in the real world.

The technological changes that have swept through our society have left educational systems largely unchanged. Over the past 20 years, an immense division appeared between the process of teaching and learning in schools and the ways we obtain knowledge. This division has been made more obvious by the fact that the process of teaching has not changed substantially over the past 100 years. The result is an estrangement of children in schools from society as a whole. Educators now question how we can best educate students raised in a world of instant information, where interactive technologies have led them to believe they can act on the world with the press of a button. What is needed is a guiding philosophy for educational curriculum and effective uses of technology. It has been proposed that this philosophy could be Constructivism (von Glaserfeld, 1989).

Technology and Constructivism
Constructivism's central idea is that human learning is constructed, and that learners build new knowledge on the footing of previous learning. In a Constructivist atmosphere, the learner constructs knowledge through discovery and exploration in order to solve real world problems with peers. According to Bruner, Constructivism is a teacher-facilitated process that places students at the center of active learning, rather than in a passive role. Instead of simply absorbing ideas spoken by teachers, or somehow trying to internalize thoughts through endless, repeated rote practice, constructivism suggests children actually invent their own ideas. They assimilate new information and modify their understanding in light of new data. In the process, their ideas gain in complexity and power, and with appropriate support, children can develop insight into their own thinking processes. Advocates of constructivist teaching say its practice is vital if America hopes to cultivate and maintain a work force capable of competing globally in the 21st century.

Schools have always mirrored the values of our society, however the technological changes that have swept through society have left the educational system virtually unchanged. It is frightening to note that as our children are growing up, they may not be receiving the instruction and knowledge necessary to function in a technological world. The task of the educational system should be to embrace the future and empower children to learn with the tools available to them. Trying to think up clever ways to use computers in a traditional classroom setting will not do the job. If we assign technology to a secondary role, which does not fully utilize its potential strengths, we are failing to use it to its fullest potential.

By using technology as part of a constructivist philosophy in the classroom, we can give our children a powerful set of tools. Technology should be thought of as an integral component of any curriculum. Computers in a constructivist classroom can be used as a writing tool, to complete spreadsheets, to compile databases, for concept mapping, to create multimedia, to author Internet projects, to complete research, and mathematical problem-solver. Computers also make it possible to exchange information between classrooms and access online information.
"The introduction of computers into the classroom changes the teachers' role, leading to decreased
teacher-directed activities and a shift from didactic approaches to a constructivist approach" (Schofield &
Verban 1988). Research has shown that teaching in classrooms with computers involved more: a) project
work, b) extensive projects, c) motivation for the writing process, d) group work and cooperative learning,
e) interdisciplinary activities, f) opportunities for students to make choices and g) a different philosophy of
teaching (Dwyer, et al., 1990). A classroom with a technology rich environment has also been shown to
involve less structure and less teacher presentation (Schofield & Vethan, 1988). The trick to teaching is to
entice and motivate the students' excitement and interest in the topic, and then to give them the proper tools
to reflect, explore, compare, and contrast. Current interactive multimedia technologies have the potential to
represent ideas in almost any form so students view the resources, creating their own meanings and
understandings of the information they encounter.

Increasingly, researchers and educators are linking Constructivism and learning with technology.
This is not surprising since many see a strong support for the principles of Constructivist philosophy in
computer-based learning environments. Computer-based Constructivist projects can take many forms, both
online and off. They do, however, all have one thing in common; they are based on a problem-solving
format. CSILE, CoVis, Computer Clubhouse, JASPER, and Web Quests are all examples of such formats.

Using a Building Block model (Dodge, 2000; March, 1995; March & Reed, 1999) integrated
technology projects can be created that will allow students to gather information, use critical thinking skills
and communicate. A constructivist technology-integrated lesson plan should be designed to bridge the
transition between teacher-led instruction and self-directed learning by students. The hope is that through
scaffolding, both teachers and students will gain experience in a learning-centered approach. One way these
projects can be created has four steps: a) determine outcomes, b) draft the project framework, c) develop
the evaluation tool, and d) design the task.

Summary

The goal for education should not be simply to access information, but to understand and use it to
solve real world problems. Technology offers educators the opportunity to move away from instructional
strategies that focus on presenting abstract information to a passive learner, to an active process where
meaning is developed based on experience. This way of teaching and learning supports the Constructivist
point of view where the learner is building an internal representation of knowledge and a personal
interpretation of experiences. Technology also offers students the opportunity to communicate and
collaborate with millions of worldwide users on the Internet.

Technology has effectively revolutionized American society. An unexpected by product of this
revolution has been the emergence of a generation of children weaned on multidimensional, interactive
media sources, a generation whose understanding and expectations of the world differ profoundly from that
of the generations preceding them. We need to give these children the education necessary to succeed in a
technological future. We need to build on children's native learning abilities and technological competence
with an instructional model that allows learners to be actively involved and engaged in a real-life arena,
which includes technology.

A Game Editor for Virtual-Prismaker Learning Environment
to Improve Teaching and Learning in Classroom

Antonio Fernandez-Caballero, Victor Lopez, Pascual Gonzalez, and Maria D. Lozano
Regional Development Institute
University of Castilla-La Mancha
02071 – Albacete, Spain
caballer@info-ab.uclm.es

Abstract: This paper describes a personal game editor developed to improve teaching and learning strategies in classroom through a learning environment called Virtual-Prismaker. Most educational games are closed in the sense that the teacher is not permitted to introduce new activities. In the context of Virtual-Prismaker project we have faced the need to open the game's educational possibilities by enabling to incorporate the educator's experiences and needs, and by enforcing the motivation children find in playing computer games.

1. Introduction
When preparing activities that are to be carried out in classroom, the teacher tries to maximize the use of available resources. Prismaker is a construction game composed of reduced number of kinds of available pieces. The main construction block is a semicube. Apart from these basic construction blocks, there are a series of additional pieces: wheels, axis, small cylinders and logos. In our context, logos are very useful and greatly improve the construction game's cognitive capacities. Indeed, logos are used to assign blocks a meaning. Teachers are able to create a greater number of different games for distinct school matters by using this highly interesting feature. Information technologies provide new tools for the creation of contents that adapt to children characteristics, to their learning capacities and to their special needs. Our research team is involved in the development of an interactive learning environment based on the physical educational game Prismaker™ [Prismaker, 2001]. The game is called Virtual-Prismaker [Gonzalez et al., 2001; Lopez et al., 2001]. Introducing new technologies in classroom does not mean substituting the teacher's work. It rather allows creating new games according to the students needs. This is the cue we are approaching in this paper.

2. A Game Editor to Improve Teaching and Learning Strategies
Computer games designed for education in classroom should allow the teacher to create and to modify the existent playing possibilities to adapt the material to the learning necessities of the different students. Thus, the central idea of our project is to offer the possibility to personalize games. Observing similar games that exist in the marketplace, we have noticed that their playing possibilities are totally closed. Our solution is to offer teachers an open game. For the currently available types of games, the teacher is in charge of creating those activities he considers to be convenient, as well as their characteristics. Here is where the teacher's educational role begins. Our virtual game editor tool is not sought to substitute the teacher's labor, but to offer him to be a decisive part in a new teaching means.

A characteristic incorporated to the game is the division in difficulty levels. This also bears a motivation aspect for the player as he is challenged to complete all the levels. The difficulty levels are based on the age of the player and the teaching matters (mathematics, history, language, etc). The student has to overcome, according to his age, the different difficulty levels to complete each matter. It is the teacher's job to associate any playing activity to a certain level.
In our solution the main raw material needed to create activities are images. We have also created a letter/word editor that allows us to create simple images containing letters, numbers and words in a quick and easy way.

3. The Game Editor Capacities

3.1. Meaning related games

These kinds of games have been incorporated as they throw two desirable characteristics for learning. The first characteristic is its memory training capacity. And, respect to the concept of association, it offers a great potential applied to any matter. Some examples are offered now. In a Foreign Language course it is possible to give the native word and the foreign word for it. An example in Geography is to show the name (or the map) of a state and the name (or a representative monument) of its capital. There is no limitation to the teacher’s imagination. Thus, it is feasible to create identical couples, to create couples with the same concept or even to create couples with some preset relationship. This way, children learn to relate concepts. The association possibilities are infinite. For example we can enumerate the following ones: learning words in several languages, relating two numbers associated somehow, comparing an image to a written expression, associating the same images.

3.2. Order related games

This second kind of games is based on composing an original image where the important thing is the order of the parts that compose the global image. The student is given the original image and the disordered pieces. Considering the fact that the important thing is the order, we have added to this type of game the possibility to create a sequence of images. We can create this way, for example, an alphabet, a sequence of images that describe a story, etc. Another possibility is to create a sequence of images where the order is the important thing. The editor offers a multiple image viewer for this case. Once we have the images, the creation of an activity game of this type is very simple. We can create image sequences such as an alphabet, a story where each drawing represents a part to the story, etc. Series or patterns are allowed too. When a pattern is being created the teacher decides the elements the pattern will consist of, along with the number of times the pattern must be repeated. A mathematical sequence could be created defining the initial value, the expression to calculate the next element and the minimum number of elements to play successfully that game.

3.3. Meaning plus order related games

Meaning plus order has been used in a game based on mathematics, so that children are engaged to learn about the basic operators in a simple way. In this kind of game, the student is offered a disordered mathematical expression, where each piece contains an image of an operand or an operator. The student’s mission is to place the pieces so that the expression is correct. Therefore, both the order of the pieces and the result calculated to evaluate the expression has to be correct. Each piece will be an integer number or one of the following operators: sum, subtraction, division, multiplication, right parenthesis or left parenthesis.

Acknowledgements

This work is supported in part by the CICYT–FEDER 1FD97–1017 grant and by the 2000020264 JCCM and European Social Fund. The authors would like to thank Corebo Moreno Rodenas and Jose Martinez Esparcia for their very helpful contribution to Virtual-Prismaker.

PDA Strategies for Preservice Teacher Technology Training

Abstract: Making technology integration relevant by eliminating the access barrier for preservice teachers is a problem that may be solved for educators of preservice teachers by the utilization of PDA (Personal Digital Assistant) devices. For approximately $250, students can be equipped with the PDA, keyboard, and software necessary to read, write, collect data, and create presentations. This paper outlines the perceptions of the preservice teachers in their beginning technology class that utilized PDAs to support their learning experiences and discusses the appropriate use of PDAs to integrate technology into classroom activity structures.

Introduction

Surveys regarding the current state of technology use in classrooms indicate that, although more students have access to computers than ever before, either in the classroom or at home, 78% of classroom teachers still view lack of access to computers in the classroom as a barrier to their efforts to integrate technology into their daily teaching practices (U.S. Department of Education, 2000). In a comprehensive survey that reviewed teacher use and teacher-directed use of computers in classrooms around the United States, Becker, Ravitz, and Wong (1999) found that “regular use of computers with students is highly dependent on access to computers” and that frequent use of computers occurred more frequently with 5-8 computers in the classroom rather than with 15-30 computers in a lab (executive summary statement on website).

The challenge, then, to educators responsible for providing preservice and inservice teachers with the skills necessary to infuse technology into their daily teaching practices is to provide teachers with options to overcome the access barrier as well as inform them of emerging technologies and practices that strengthen and support their inclusion of technology into daily classroom routines and practices.

Meeting this challenge may have received a helping “hand” with the recent drop in prices of the Personal Digital Assistant (PDA), a handheld device that allows a portable and relatively inexpensive means of gathering, recording, and organizing information into meaningful forms of communication. For approximately $250 per student, the teacher is able to provide a student with a PDA, black and white camera, and a keyboard that will enable the student to take notes, jot down ideas, record thoughts, memories, words, and responses to readings/experiences, collect pictures for creative projects, as well as support time management skills needed for the successful student.

The research described here provided preservice teachers currently participating in the beginning technology course, Teaching with Technology, with an opportunity to explore the application of handhelds to elementary classroom instruction, and then investigated their perceptions as to the factors perceived as most valuable in influencing teachers to use this emerging technology as a part of their students' everyday learning activities.

The Study: The Participants and Data Generation/Analysis
Investigating the perceptions of preservice teachers as to the factors that will influence teachers to use handhelds as part of everyday learning and teaching activities that integrate technology into the instruction required two components. First, the study required the selection of a purposive sample of participants with knowledge and understanding of the capabilities and functionality of the handheld, as well as participants knowledgeable about the use of technology seamlessly applied to instructional design. The participants in this study were chosen from among the preservice teachers currently enrolled in a university technology integration class, Teaching with Technology, that is one of three courses that comprise the first block of the Elementary Preservice Teacher Certification Program. These participants also expressed an interest in learning to use emerging technologies as a part of daily classroom instruction, and had constant access to computers as they were currently working in a technology-rich environment as a part of the technology course. These parameters were established so that the perceptions of informants with similar technology training backgrounds and technology support could be explored. The sampling was designed to include a broad variety of informant backgrounds based on life experiences, age, unique observation field situations, and a variety of teaching expertise (beginners vs. novice preservice teachers).

Secondly, the research required a study design that placed the voices of the participants and the telling of their perceptions at the center of the inquiry, one of the assumptions key to constructing research in the constructivist paradigm. Naturalistic Inquiry, the strategy chosen for this study, provided the researcher with appropriate methods necessary to explore preservice teachers' perceptions of technology-based activities deemed valuable to their teaching practices. Defined as a collection of methods with "the commitment to studying human action in some setting that is not contrived, manipulated, or artificially fashioned by the inquirer" (Schwandt, 1997, p. 102), Naturalistic Inquiry relies upon a study design which allows the findings to "emerge" from the data as the value systems of the researcher and participants "interact in unpredictable ways to influence the outcome" (Lincoln & Guba, 1985, p. 41).

The constructivist design occurred in two stages. During the first stage, participants were given the opportunity to explore, handle, and acquire competency with the use of handhelds, as well as probe the application of handhelds within the instructional design process. To do this, the participants attended two workshops. The first workshop instructed participants in the basic use of handhelds; the second workshop instructed participants in the integration of handhelds into the instructional design process. Between the workshops, the participants were given a handheld and a keyboard and asked to use the handhelds on a daily basis by taking notes, using the calendar feature, maintaining an address book, and beaming documents between study participants. Participants provided the researcher with weekly reflective journals that documented their learning experiences during this first stage.

After the second workshop, participants participated in a series of unstructured, open-ended interviews initiated with a single broad-focused question: What are the factors you perceive as most influencing elementary teachers use of emerging technology, such as the handheld, as a part of students' everyday learning activities, as well as a part of the teacher's everyday teaching activities? The interviews were tape-recorded, transcribed, and member-checked through follow-up interviews with the informants. Other data in the form of related documents, such as e-mail conversations with participants, reflexive journals of researcher and participants, examples of lesson plans and student activities created during the process, were collected and analyzed. A peer-debriefing group met weekly for the purpose of reviewing the analysis of documents and interpretation of resulting interview data.

Data analysis in a study that uses naturalistic inquiry methods is inseparable from data generation and collection; thus the process of data analysis began with the first contact between researcher and participant. Data generated from each contact with participants, through interview, observation, or the creation or review of documents, helped to form several tentative findings, which led the researcher to probe some areas of discussion more deeply or change strategies for observation and data generation. Adjusting data generation procedures continued as additional data were generated and tested against the evolving themes. The process of generating data, unitizing data, and developing categories and themes from the data continued until reaching thematic saturation, or the point at which no more new categories and themes made themselves apparent (Erlandson et al., 1993).

The Findings

These findings are preliminary as the final interviews are still being member-checked, but two main themes (subject to refinement as the data collection/analysis continues) have emerged:

Theme 1: Participants perceived handhelds as an invaluable tool for collaborative learning environments and a catalyst for development of learning communities. Participants overwhelmingly expressed satisfaction with the capability of handhelds to collect data/resources and ease with which that information could be shared with others, either through traditional printing methods or beaming files to others to use. Participants perceived this ease of
distribution of data and the process of collaborative sharing as promoting the development of a learning community that supported their learning needs.

**Theme 2:** Participants perceived handhelds as an invaluable instructional tool because it provided technology that was easy to use, supported the learning needs of students often supported by technology, and was portable and accessible. Participants valued the handheld as an instructional tool for students because the skill level required to use the tools was minimal, could be acquired with minimum classroom time, and, student work could never be “lost” due to the student carelessly closing an application without saving. In addition, with the view that, as students, they personally used technology mostly for taking class notes, writing short paragraphs for various purposes, and keeping up with the assignments, participants viewed the capability of the handheld to provide word processing, editing, and beaming functions as supporting the majority of their learning needs that they were currently supporting with desktop computers. And, finally, the fact that this capability could be taken anywhere and used anytime was perceived as providing users with a portability that could not be provided by laptops or desktop computers.

**Conclusion**

Although the purpose of this inquiry was not to provide findings that are representative of all preservice teachers, but to explore the perceptions of these 12 participants as they reflected upon the value of handhelds in the learning environment, these findings may suggest possible consideration to the various contexts of using emerging technologies as enhancements for learning environments. Strategies for using handhelds as a part of a successful learning environment may include integrating handhelds into instructional designs that require the following:

- Collaborative learning processes or the development of a learning community,
- Writing Process or intensive development of writing pieces, or
- Portable tools for remote data collection.

Abstract: This paper is a report of user studies for developing learning strategy tool software for children. The prototype software demonstrated is designed for children with learning and behavioral disabilities. The tools consist of easy-to-use templates for creating organizational, memory, and learning approach guides for use in classrooms and at home. User studies that were conducted with software prototypes included two rounds of expert review, usability testing in a lab setting with teachers and parents, a focus group with parents and educators, and “thinkaloud” observations of children using a sample of the tools. Results were used in improving the software, preparing the teacher orientation module, and designing online supports for users. The most useful dimensions of evaluation were found to be direct observation of children using the software and messages contributed by a high school student with learning disabilities to the Online Focus Group.

Service to children with behavioral and learning disorders is a high priority in the U.S. (Elam, Rose, & Gallup, 1998; Kay, 1999). Currently, federal mandates require that such children be served in the “least restrictive environment” by providing appropriate supports and effective strategies to ensure success (IDEA97). Common problems faced by these students in regular classrooms are difficulties maintaining attention, organizing work, managing time and materials, and responding with accuracy (Lewis & Doorlag, 1999). With these deficiencies students are at-risk for increased behavioral problems, failure, and ultimately, removal from these classrooms. Research shows, however, that strategy instruction in these skills can help students become successful learners and managers of their own behavior (Swanson & Hoskyn, 1998).

Electronic Performance Support for Children with Learning and Behavior Problems

Computer-based training and support mechanisms are an innovative approach for helping children gain control over personal behaviors. While electronic performance support systems have been used in education and industry to support adults in learning new skills “at the right place, right time, right form” (Laffey, 1995), work is scant in applying these principles to the development of software tools for children. If the goal of EPSS software is appropriate for adults—to provide whatever is necessary to ensure performance and learning at the moment of need in a seamless activity—then it offers the same potential for helping children improve performance in their learning environments. If effective, EPSS support tools for children improve their
independent functioning, reduce teacher time re-focusing their mistakes and energies, and offer lifelong skills for success.

This paper reports the design process followed by the developers in creating a new set of EPSS tools to help young children learn and use these school survival strategies. These unique materials include four components: (1) strategy software tools for children, (2) an information resource database for teachers, (3) a web-based orientation module for teachers, and (4) online resources and discussion lists to support teachers and parents (refer to conceptual framework in Figure 1) (Fitzgerald & Koury, 2001-2002). During the development period, a variety of user studies were conducted with children, parents and educators to ensure that the materials represent best practices in the field. This paper summarizes the user studies and initial findings and highlights important issues in software design for children.

Related Work: Previous Applications with EPSS Tools with Children

Computer-based training and support mechanisms are an innovative approach for helping children gain control over personal behaviors. Although there are limited data on the use of computer-based instruction to support behavior change in children to date, research results are promising. Fitzgerald and Werner (1996) reported success with a computerized verbal mediation essay as a cognitive retraining procedure to assist a student with significant behavioral disorders in changing his behavior; the computerized essay provided consistent practice and focused the child’s attention and thoughts on behavioral choices and consequences. In another case study, the same researchers reported a procedure in which software templates were developed for a student to create self-monitoring materials.

Following these early studies, the developers created a series of EPSS tools for children that supported children in using self-management skills in classrooms (Fitzgerald & Semrau, 1998-2000). The children’s software programs, First Step KidTools for ages 7-10, and Second Step KidTools for ages 11-14, provide a series of progressively complex templates to be used as tools. In using the tools, children identify behaviors for self-improvement, identify specific self-control strategies they want to use, prepare self-talk statements to guide their use of the strategies, and create/print-out materials to support their plans. Both software programs consist of tool templates that are kid-friendly with colorful graphics, text-with-audio directions, multiple examples, simple formats, and automatic record-keeping capabilities. To use the tools, the child simply clicks on “hot words” on the template form to enter personalized content and then print out the completed form for use in the classroom or home.

Qualitative methodologies were used to gather multiple data on the usefulness of the approach and important design features in the software. Several important design decisions were made based on these studies that have been applied to the production of the new strategy software: (1) include the option of spoken text for poor readers; (2) use children as on-screen guides through the tools; (3) use children’s voices for narration; (4) provide access to help screens that can be accessed while using the tools; (5) provide multiple options to re-start or make changes; and (6) put the child in charge of creating his/her tools using natural language. Pilot testing with KidTools in two states demonstrated that children were able to independently use the tools and were motivated by the computerized tool format. Teachers reported improved motivation and self-control in classrooms. The findings from KidTools are extended to the production of KidSkills with its new focus on learning strategies. The previous work ensures appropriate literacy and ease-of-navigation features are included in the KidSkills design (Fitzgerald, Watson, Lynch & Semrau, 1999).

Conceptual Framework for the Design of KidSkills

Recognizing the importance of ecological variables surrounding an innovation systems (Peled, Peled, & Alexander, 1994), multiple products are being developed in a systems approach. The primary components of this framework are illustrated in Figure 1: development of the EPSS software, development of a resource information database for educators and parents, development of an orientation module, and use of online focus groups and a web-based hotline to share information, provide support, and disseminate materials during implementation.
KidSkills, the children's software, offers strategies based on cognitive-behavioral approaches that help youngsters change cognitions (thoughts, beliefs, self-talk, cues) and behaviors (actions) within a problem-solving framework to gain successful outcomes. These approaches have increased in popularity during the last two decades as researchers have documented their effectiveness (Gresham, 1985) and curriculum developers have designed and disseminated teachable programs for implementation in schools (Anderson, 1981; Nichols, 1999). To date, there have been no known precursors to this work that combines electronic performance support tools along with strategy training for teaching cognitive-behavioral strategies to young children.

Fig. 1 Conceptual Framework for Development of KidSkills

The KidSkills Prototype

There are two levels of KidSkills. First Step KidSkills is designed for ages 7-10 and Second Step KidSkills for ages 11-14. There are 18 tools in First Step KidSkills organized in the categories of: Getting Organized, Learning New Stuff, Doing Homework, and Doing Projects. There are 30 tools in Second Step KidSkills organized in the categories of: Getting Organized, Learning New Stuff, Organizing Information, Preparing for Tests, Doing Homework, and Doing Projects. Information on these strategies is provided in a resource information database program, Skill Resources, to provide educators and parents resources to assist children during implementation. A teacher orientation module is currently being developed, including a PowerPoint presentation, demonstration videos, and a web-based hotline for assistance.

The software contains colorful graphics, text-with-audio directions, and simple formats. Graphic characters serve as “guides” to the different tools and provide audio directions in children's voices. The text and audio in KidSkills allow for children to enter text in their own words. The audio directions supplement the simplified text instructions and can be turned on or off. To use the tools, the child simply clicks on “hot words” on the template form to enter his or her content and then prints the completed form for use in the classroom or home. Children have instant access to examples with directions and flexible ways to re-start when desired. The program automatically enters the child's name, date, and establishes an audit trail for record-keeping purposes. These audit trails are instrumental in tracking the development of children's thinking and skill decisions.

Figure 2 displays the main menu screen for Second Step KidSkills. Children select tools from categories by clicking on the hot areas on the screen or by using the pull-down menu. Figure 3 shows an example of a completed Second Step tool. In this example, the KWL (Knows...Wants to know...Learned) tool provides a learning strategy to help the learner focus on important information when learning new material and integrate
new information with his/her current information. This helps the learner re-structure knowledge. The child would enter the following information: the class, topic, source of information, what the child knows, wants to learn, and what was learned. The tool could be used prior to studying to guide learning, or as a follow-up to review information.

User Studies in the Developmental Process

The software development process is recursive, going through several phases of development → testing → revision based on procedures recommended by designers of children's software (Druin, 1999) and evaluators of interactive learning systems (Reeves & Hedberg, 2002). The first step of formative evaluation, design testing, includes three processes: 1) review of content and interface design by experts in learning strategies and children's software design, 2) observations of adults working with the prototypes, and 3) focus group meetings with parents and educators to discuss the tools and consumer training needs. The second step of formative evaluation, usability testing, includes three processes: 4) observations of children using a sample of the tools while collecting “think-aloud” transcripts, 5) examination of tool artifacts, and 6) expert reviews of the completed software. These six developmental steps lead to a full beta testing of the software, training, and support modules.

Expert Review of Paper Prototypes

Paper copies of all the tools were reviewed by eight content experts, including teachers, administrators, university personnel and a parent of a learning disabled child. Each reviewer used a structured questionnaire to provide feedback on screen design, content of the tools, terminology for children, and other literacy features. Some of the reviewers had prior experience using the KidTools program and were able to give suggestions for operability. Based on these reviews, some of structural elements and terminology of the tools were changed to make them more understandable by children with learning disabilities; some tools were re-conceptualized; color coding was added to guide entries; and two new tools were created.

Design Testing in a Lab Setting

An open lab time was scheduled at a statewide special education conference for educators and parents to “play” with the KidSkills prototype. During this time, two graduate research assistants staffed the lab and observed 46 adults using the software, watching for difficulties or unusual routines. Field notes were made to record comments of participants, and feedback forms were collected. Overall ratings were 8 to 9 on a 9-point Likert scale (9 being the highest). Positive comments were that the program would be fun and easy to use, the strategies would be useful for students with learning disabilities, the audio directions were helpful, and they appreciated the interactivity and multisensory approaches. Some potential problems identified were difficulty in using pull-down menus for children, desire for more graphics and larger hot spots, use of tab key to save text.
entries, desire for spell checker and thesaurus, and navigation back and forth between screens. Problems that were identified for implementation included teacher training, scheduling use within the school day, access to computers at home and school, and need for quick instructional resource.

**Online Focus Group with Consumer Group Members**

An online focus group was held with members of the target consumer groups, including one parent, three classroom teachers, three teacher-trainers, and a high school student with learning disabilities. Project staff also participated in the discussions. Four open-ended questions were used to engage participants: (1) acceptance and use of the software, (2) potential implementation problems, (3) recommendations for training and support, and (4) other suggestions. Discussion threads emerged within these broad areas. The messages were coded for themes using the qualitative analysis program, NVivo. With this text analysis program, information can be linked and examined across multiple sources, leading to an integration of the results (Richards, 1999). Some of the concerns that were raised were earmarked for observation of tool usage with children, particularly use of the tab key, size of text entry fields, quality of audio narration, and navigation problems. Discussion of implementation issues were helpful in designing the orientation module and planning the web hotline.

**Think-Aloud Observations of Children Using Working Prototypes**

Twelve children with mild-moderate disabilities were selected to participate in usability testing. These students all had learning disabilities or behavioral disorders, grades levels 27, ages 8-14, and received academic programming in resource or inclusive classrooms. The selected children used the software in a one-on-one setting with project staff. After an initial training period with one of software tools, children were asked to "think aloud" as they worked with the software to produce materials using three different tools (Smith & Wedman, 1988; Someren, Barnard, & Jacobijin, 1994). An observer audiotaped the sessions and made field notes in order to record the children's reactions to the interface and the overall operability of the software using observation and interview guidelines. These results were analyzed using NVivo.

**Examination of Artifacts Created by Children Using Working Prototypes**

The artifacts produced by the children were examined to answer any questions raised during earlier stages of review or suggestions made about the tools during the Online Focus Group. The software contains a complete audit trail that records out to files all tool choices and entries made during usage.

**Expert Reviews of Completed Software**

The completed software tool programs will be sent to a panel of experts in July, 2002. The reviewers will have background in special education (cognitive-behavioral interventions and learning strategies) and two of the reviewers will have expertise in human-interface design of software (EPSS architecture and design for children). A systematic interface design will be conducted using an assessment guidelines based on procedures for user interface studies (Schneiderman, 1998). The guidelines include overall reactions, screens, sound, graphics, content, terminology, and operability. Reviewers will submit a written report with recommendations.

**Putting the Pieces Together**

Although each formative evaluation procedure yielded valuable information and useful suggestions, we found summation and integration of the information to be most critical. As discussed by Maslowski & Visschier, all the possible dimensions of formative and summative evaluation are rarely conducted due to financial and time constraints (1999). Their suggestion is to evaluate the dimensions where designers face questions for the greatest benefit. It is easy to respond to each procedure with revisions and further testing, as recommended in the recursive testing process, yet this approach can lead one down false paths based on partial, rather than complete, findings. For example, adults viewed the tools and raised concerns about navigation and the use of the tab key, yet observers of children found that with very little guidance, children quickly learned to navigate and enter information into tools. Adults questioned the clarity of the children's voices for narration, yet observers reported that children found the voices appealing. Adults who tested the software found it easy to use, yet our high school student strongly recommended a hotline for teachers to answer computer-use questions.
It was clear that conflicting feedback was provided by different "voices" of expertise. The most useful dimensions to us were the direct observations of children using the tools and the messages to the Online Focus Group provided by our high school student with learning disabilities. He grasped how the tools could be used in classroom settings and the abilities and limitations of teachers in supporting roles. Above all, we learned to integrate the voices of children during the design process (Druin, 1999).

1. Introduction

Inquiring databases through the Web, in terms of visual interface, is currently an active area of research [15,16]. The main problem is to provide a user-friendly interface to query remote database. Most systems provide three kind of querying: text search engines, form-based interfaces and natural interfaces. An alternative way to query is based on icons. Starting from previous works [1,2,4,5,13], a client-server Iconic Visual Query System (IVQS), called IVQS Server, has been developed. This system allows the user to query remote and different multimedia RDBMS through the Web using an iconic interface. The system offers two kind of iconic querying: query icon, where an icon represents a query, and entity icon, where an icon represents an entity (a table in a relational Database). An iconic representation of a query can make easier for the end-user or the inexpert user to query a remote database without knowing the internal structure of the database or compiling exhausting forms. Our system has been used in education fields obtaining good results. IVQS Server has been developed as an applet Java on client side and a Java application on server side, so it’s completely platform independent and it doesn’t need any installation on client side.

2. System Overview

The IVQS Server prototype is a Visual Query System developed at ENEA's Usability Lab to access and query remote databases through the Web. The system allows to create and execute queries to remote databases and to have a multimedia results visualisation. The system has an architecture client-server where the client is a Java Applet and the server side is a Java application, both executable directly through a Java-enabled Web Browser (without needing any installation). The system provides two kind of iconic querying (fig.1):

- **Query icon.** Each icon represents a query. More icons can be grouped inside a folder so that the icons are structured in a tree. The user can execute the query double clicking on the icon.
- **Entity icon.** Each icon represents an entity (a table in a relational Database). Between two or more entities a query can be associated. Dragging an icon entity and dropping it on to another one, the associated query, if exists, is executed. For example, if there are the entities (tables) DEPARTMENT and EMPLOYEE, it can be associated a query that is the join on the common field DEPARTMENT_ID.

An Icon Editor has been integrated both to create and to associate an icon to a query or to an entity. In this way the user can create his own icon or import an existing image specifying an URL. The system provides a multi-user environment with user identification/password authentication. Each user can have, in a list of his own favourite queries in a specific area. Two kind of user are handled:

- **Expert User (Super User).** This kind of user can manage the system to create and modify queries, entities and can set up the result display layouts. The user has a good knowledge of relational databases and of their structure. The user can create queries visually selecting databases, tables, attributes and conditions. The system can execute queries to the most known relational databases such as Oracle 8.x, 9.x, MS SQL Server, MS Access, Informix, Sybase and ODBC/JDBC-compliant data sources). In particular, choosing two or more different database, he’s able to build a query involving tables from different remote RDBMS. The user can use the system by himself or as an administrator for a set of end users.
End User (*User*). This kind of user uses a structure already set up by a super user. The user deals with predefined queries and entities. Typically he's neither a computer nor a database expert; the user can use the system without knowing the internal structure of the databases. The user can have his own set of favourite queries.

Every data related to the user is stored, by means of IVQS server side, in the system database.

IVQS Server provides two kind of result display: table and form. In the form result display it's possible to customise the visualisation layout in terms of object position, font type, size, style and colour. Objects can be text labels, images, Web resource links (web pages, e-mail address, executable files) as URLs. In the latter case the user can open the resource that will be handled by the browser. Multimedia objects, such as movies or sounds, are placed in a specific area Media Area.

Typical uses of IVQS Server:

- IVQSS as a visual database interface for the end user, who can access a set of remote databases in a quick and easy way using predefined queries pre-built by the administrator.
- IVQSS as a tool for long distance learning, both for the administrator who can manage the students database and for the students as an interface to access structured information collected by multimedia cards. In particular with IVQSS applications in natural science and materials have been implemented.

3. IVQS SERVER Architecture

The system architecture has three modules: IVQS Server, IVQS applet, the client, that is stored in the Server and the IVQS Web Site. When the client Web browser sends the request, the Web Server sends back the applet, which starts being executed on the client. The applet, because of its security limitations [14,19,20], can open socket connections only to the originating Server. We need a server side application, which can access remote database and talks with the applet. We used a Java application at server side, it can access various kinds of RDBMS (Oracle, MS Access, Informix, etc.). In this way the applet communicates with the application server to send query and to get back results in XML format. After the first generation of IVQS [22] has been implemented the IVQS Server release with the following functionalities: User management, User data management, Query management, Query Optimisation, Asynchronous Query, Query Repository, Query Statistics, Query&E-mail Services and Dynamic Web Page Services.

4. Experimental Results

IVQS Server has been used on a set of existent databases, each one very different from the other in terms both of information and target users. Here is the list of the databases where IVQS Server has been applied:

1. FAD Database (Long distance learning), ENEA web site for long distance learning on the Internet.
2. G7 Global Inventory Project (GIP). An Internet inventory of G7 IT projects. The target users are Internet ones.
3. Prosoma (PLUS), EU Web site, a multimedia database containing the most relevant project results in Europe.

The target users are researchers, enterprises, technology operators and the EU. In all these experiences, IVQS Server has been tested by the users to measure its Usability [5]. The results obtained, in terms of user satisfaction and user efficiency [10], showed that a query iconic representation allows a better perception in user's mind making it easier to memorise [6,7,8].

5. Conclusions and future work

The increasing number of Web users is looking for convenient ways to search information on the Net and to collect and query data from different sources through the Web [2,12,16,18]. It's necessary to develop new alternative tools for such tasks. It has been introduced IVQS, a Visual Query System to query remote database through the Web.
using an iconic interface, developed and tested at ENEA Usability Lab in collaboration with University of Rome "La Sapienza". The iconic interface that is alternative to the form-based web pages which are the most common interface nowadays. The system has proved that an iconic interface is really easier to use for large end-user groups. As future features it's planned to produces an increasing on multimedia web services provided.

CAN DEVELOPMENTAL STUDIES LEARNERS SUCCEED IN DISTANCE LEARNING?

Rob Foshay, Ph.D.
Vice President, Instructional Design & Cognitive Learning
PLATO Learning, Inc.
E-mail: rfoshay@plato.com
URL: www.plato.com

Abstract
This action research program involved implementation of distance education-based developmental studies programs for mathematics using PLATO via the Internet at 8 participating institutions. Twelve characteristics were found to be in common over the most successful of the programs. We present the twelve characteristics and summarize overall effectiveness of the programs.

The Internet and distance learning hold untapped potential to change the culture, curriculum, and course of educational institutions around the world. But, most distance education models assume highly skilled and self-motivated learners: exactly the opposite of the typical developmental studies learner. The League for Innovation in the Community College and PLATO® Learning, Inc. initiated an action research project exploring the questions and challenges of implementing successful distance learning developmental math programs for community colleges across the country.

College Participants
Selection of participants from League colleges and League Alliance members was based on specific commitment criteria. Each participating college was asked to designate two faculty members and commit training and service time to research and program development. The research consortium initially included nine colleges; however, eight fully implemented PLATO On the Internet (POI) as part of their developmental mathematics program:

- Central Florida Community College, Ocala, FL
- Delta College, University Center, MI
- Kapiolani Community College, Honolulu, HI
- Kirkwood Community College, Cedar Rapids, IA
- Moraine Valley Community College, Palos Hills, IL
- Miami-Dade Community College, Miami, FL
- Santa Fe Community College, Gainesville, FL
- Sinclair Community College, Dayton, OH

PLATO on the Internet Courseware
PLATO on the Internet (POI) courseware is a modular, self-paced, computer-based learning system that offers students interactive learning opportunities in mathematics, reading, English, and core work skills with over 2,000 hours of instructional content available. As a comprehensive academic and applied skills courseware system, PLATO uses computer-adaptive integrated learning processes for student assessment, prescriptive placement, interactive instruction, and evaluative testing and feedback.

Project Goals
The purpose of this project was to explore critical success factors for computer-based distance learning in developmental math programs during a summer trial implementation session and a full fall semester term. College participants, League research team members, and PLATO service teams outlined four areas of investigation:

- Development of effective, individualized, open entry/open exit programs for developmental students via distance education
- Cultivation of learners' motivation through the use of technology in developmental studies programs using distance education
• Exploration of successful developmental student profiles using distance learning technology
• Effective combinations of campus-based support service and distance learning delivery systems as models of success for developmental learners

Formative Conclusions

The study identified these critical success factors:
• Easy Access to Internet and Easy Navigational Courseware.
• Technical Support.
• Alignment of Online Courseware and Course Objectives.
• Individualized Instructional Format.
• Student Recruitment and Counseling.
• Orientation.
• Student Connections
• Faculty Development.
• High Standards of Quality and Content Development.
• College Leadership and Program Support.

Abstract. The Electronic Portfolio initiative in the College of Education at the University of Florida represented two years of our best efforts at matching the current research on portfolios to a systemic project for all future teachers. It was therefore surprising for one of the authors, while on a Fulbright to the University of Porto in Portugal, to find an independently developed electronic portfolio project that had so many things in common with the project we developed at the University of Florida. In this session, rather than describing the projects in detail, pointing out similarities and differences, we have decided to try to isolate the factors that caused our surprise.

The Electronic Portfolio initiative in the College of Education at the University of Florida represented two years of our best efforts at matching the current research on portfolios to a systemic project for all future teachers. It was therefore surprising for one of the authors, while on a Fulbright to the University of Porto in Portugal, to find an independently developed electronic portfolio project that had so many things in common with the project we developed at the University of Florida. In this session, rather than describing the projects in detail, pointing out similarities and differences, we have decided to try to isolate the factors that caused our surprise. After all, it isn't everyday that two independent teams of research-aware educators come to the same conclusions about the way any educational project should be run! Seriously, we believe a brief investigation of the issues facing electronic portfolio implementers may prove informative. We have worked and conferred with several groups who are either actively working with electronic portfolios or working on developing an electronic portfolio initiative. We have also spoken with professors who have lost faith in portfolios as a meaningful educational experience. Some or our anecdotal experiences, which we maintain are insights, frame the views that follow.

Mention the word portfolio to a room full of educators and many will complete the phrase with the word assessment. Portfolio assessment - the words seem to be inextricably linked. Yet a vast amount of research related to portfolio initiatives (Lyons, 1998, Paulson & Paulson, 1990, Wolf, 1991) is skeptical about applying any standardized or generic assessment procedures to the evaluation of a student's portfolio. This is due in part to the fact that unlike an assignment, a portfolio can be thought of as belonging to the student and maturing over time. Electronic portfolios can be maintained and updated dynamically over time and there are many reasons to promote portfolio development that transcend individual courses or even school years. By encouraging students to continue the revision of the work they have done, and in particular to revise their rationale for their work (as in the case of an evolving philosophy statement, for example) professors directly apply research findings on reflective practice. Indeed, if portfolios are viewed from the perspective promoted in much of the portfolio research, they provide an extremely rich environment for reflective practice. In addition, portfolios can be used to make connections between disciplines and between student experiences and generally accepted accomplished practices. In these cases, connections are being encouraged in a way that helps a student link specific scenarios or experiences to more global practices. Since portfolio building is the construction of a virtual representation of one's ideas and experience, connections between a student's work and the larger educational themes s/he is studying make sense. We would
argue that working from experience to more general theories is more effective than studying theories waiting for an
exemplar, and portfolios encourage the former.

Similarly, we feel strongly that predefined rubrics and checklists limit the power of personal portfolios. If a
student is going to reexamine positions or ideas s/he promoted in the past in a meaningful way, can that evaluation
be scripted? Can it be scheduled? How does one evaluate an individual student’s portfolio in a generic way?
Despite the strong connection between a portfolio and reflective practice, most systemic initiatives require a clearly
defined, almost formulaic way of communicating the assessment process. Consequently, many professors begin to
create checklists, or two dimensional checklists and rubrics. Unfortunately, description becomes prescription
(Clark, 1979) and soon students begin to lose ownership of the portfolio, then they lose interest, and ultimately,
the portfolio becomes a typical assignment. If portfolio development is to be a personal experience, it must be
evaluated on a personal level, if it is to be evaluated at all. Providing rubrics, in addition to removing student level
choices about portfolio makeup, can easily lower the bar with respect to quality of the finished product. According
to Spiro (1991), “instead of retrieving from memory a previously packaged ‘prescription’ for how to think and act,
one must bring together from various sources, an appropriate ensemble of information suited to the particular
understanding or problem solving needs of the situation at hand.”

On the other hand, in order for a system level portfolio initiative to work effectively, faculty have to
understand what is expected of students. More than that, faculty should be instrumental in envisioning what
students will produce. In most universities it is difficult to coordinate a system wide effort with subjective
evaluation procedures. Although it is possible, it requires setting up subsystems to handle a process which may
include time consuming interviews and quality communication between staff members. It is much easier to publish
guidelines, or rubrics, or checklists than it is to evaluate in context, on a personal level. Consequently, most
systemic portfolio initiatives either bow to the difficulties and simplify the assessment process, or set up
straightforward procedures from the outset. Of course, this “conspiracy of convenience” or reductive bias (Spiro,
1994) is related to larger issues involving any movement towards experiential or problem-based learning (Schon,
1983). According to Ramsden, “if enhancing the quality of student learning is the primary goal, it is imperative to
prevent the task of collecting and demonstrating from overwhelming the process of reflection and change.”
Ramsden goes on to say:

There is now a widespread view in academic development circles, derived directly from the
student learning research, that we should concentrate on learning, on what the learner does
and why the learner thinks he or she is doing it, rather than what the teacher does (Shuell,
1986: Biggs, 1990, 1993). And, if teaching is about helping to make learning possible,
assessment becomes defined as being about understanding students and what they have learnt.
Effective assessment helps students develop the skills of self-assessment... Luckily, if we get
the improvement part right, the accountability part is generally sure to follow. Good evidence
of improvement is automatic evidence of accountability (Ramsden, 1994).

In this light, we can see that in order to develop a truly student centered program, professors (or project
directors) must focus on improvement in student performance and link accountability to related indicators. In other
words, professors must trust themselves and their students to do quality work. It is the acceptance of this fact that is
somewhat rare, and it is this we found in the portfolio project in Porto. There was general agreement about the idea
of nurturing quality over time and avoiding rigid guidelines “handed down” to students. We both agreed that our
problems had to do with the difficulties and potential of a single, particular student at a specific time, to say the
things, to discover the things, to communicate the things, to build consensus about the things that allow and
empower that particular student to understand.

It is often difficult for professors and faculties to operationalize this student-centered approach even though
most philosophically embrace it. But using a student-centered approach to portfolios has several consequences that
directly affect learning and ultimately, program. For example, in both Florida and Porto, rather than portfolio entries
being selected by the teacher, students select their own entries and are then asked to provide a rationale for their
choices that explains why they selected the work to be included. As it happens, students have difficulty providing
this rationale (professors from other universities have also noted this difficulty). As a result of the students’
difficulty, in Florida faculty dialogues took place, which led to discussions about course adjustments. Also student
interviews were modified to focus on rationale statements, thus providing the student with a forum to delineate his
or her thinking. We embraced and promoted what Ehrmann and Lewis (1997) called DIATing (Doing It Again Thoughtfully). Significantly, during the design phase of the portfolio initiative in Florida, a large percentage of faculty held to the belief that professors rather than students should specify what appears in the portfolio. If that view had carried the design, student weaknesses would have not been identified, and steps to address the weaknesses, that is, modifications to the program, would have never been made.

Our experiences in Florida and the supportive comments made by professors in Porto and elsewhere have strengthened our commitment to student-centered education based on the development of an electronic portfolio. We consider the portfolio to be a perfect vehicle to promote the transition from teacher directed to learner-centered education.

Abstract: This paper reviews some of the key issues of what we believe should be the cornerstone of a project-based learning approach with ICT and net-based multimedia learning resources. It refers to the LAVA Learning project where pedagogic, learning resources and computer-based tools have been developed to support a complete learning environment. The project ended up creating a new project tool for this approach, and learning material and specialized content were made available to users of this tool. Content of all media types was provided a primary focus on text and video material. Curriculum from different content providers was linked together to constitute a source of learning materials.

Introduction

In Norwegian public schools there is a considerable focus on project based learning as it is required by the Norwegian National School plan, L97, see (L97). The schools were also to start using information and communication technology (ICT) in all subjects. At that time the teacher experience was low in both areas, especially ICT. Internet was there, but net-based learning resources lacked and so did broadband networks.

The LAVA1 Learning research project was launched trying to design a prototype learning suite consisting of what could be the next generation net-based curriculum and the next generation learning technology on the premises of the pedagogy of project based learning. The research team has been given a total funding of nearly 3 million US$ over a three year period to determine critical factors in the nexus of these three areas.

At the start, we found considerable prior work in pedagogy in the literature, some on appropriate content, and a large body of work in technology and tools for ICT use in schools (with links to pedagogy). Much of the work targets mathematics and science. However we didn’t find any projects where the three areas of research were conducted synchronously.

Our focus, and the purpose of this paper, is the combined development of pedagogy, net-based curriculum for project work, and computer technology to support this pedagogical approach in the humanities and social sciences at a school level. The objective of the work has been to create a learning environment that stimulates the pupils towards explorative discussions in a given topic. We therefore have chosen to use the physical arena of collaboration that exists in the schools instead of creating a virtual community on the net. We have also decided to let the pupils in groups of 4 share the main computer in the project work to stimulate discussion and cooperative creation of the learning projects.

This paper presents some of the major decisions made and results of the work done in the project LAVA Learning’s second field trial (of three). We start with the pedagogical approach to project based learning and its impact on content. We then point out the requirements for suitable ICT tools that we found to be a consequence.

1LAVA is a Norwegian acronym for “delivery of video over ATM networks”, a collection of projects with a technology viewpoint on video. The ATM is left now focusing on learning as one application of high quality video streaming.
of the approach. Commonly used software tools were evaluated but found to fall short or our requirements leading us to develop our own net-centric multimedia production tool called "Slime".

Project work as a pedagogical approach

As already indicated the pedagogic focus in Norwegian schools has turned towards more use of project-based learning and use of ICT in all subjects. As discussed by Roschelle et.al. in (Roschelle 00), learning is a complex task. Pedagogic approaches, curriculum and its use, the teacher's experience, the social and physical environment and several other factors affect how children learn. Changing one factor, like infusing PC's into the classroom, will not by itself dramatically change learning. Getting the most from the use of computers should also involve changes in the rest of the learning environment, especially the teaching methods used and the curriculum. In the endeavor to improve learning conditions, one should also pay attention to results from recent cognitive research, for instance in (Bransford 99). It has been shown that the four fundamental characteristics—active engagement, participation in groups, frequent interaction and feedback, and connections to real-world contexts enhances the learning processes significantly.

In project work learning takes place during the creative process of producing a project report and during the discussions among the pupils when they are engaged in doing so. The pupils formulate a problem statement to be investigated, and find and compile information that can be used to elaborate and answer the principle questions raised by the topic of concern. Learning facts and relations between concepts takes place as the pupils pose questions, confirm or reject each other's suggestions and explain their position. The teacher, the content available to the students, and the tools used to compile and document students' efforts, must all contribute to keeping the right focus on the pupil's discussions. When focus is lost, learning will be less effective and subsidiary or irrelevant threads evolve.

The pedagogical researchers involved in LAVA Learning have been pro-active in designing a learning scenario that incorporates the use of net-based curriculum and computer based project tools in a natural way. The scenario based upon was the following:

1. Go through the start page designed by the project (see below) and follow all linked material that you find interesting.
2. Discuss the subjects of the start page and decide upon a main problem to be investigated (had to be accepted by the teacher).
3. Brainstorm the actual subject identifying possible sources of information.
4. Iteratively build an electronic project report using a combination of net-based and self-produced content.
5. Finalize the project as a class presentation.
6. Present the project to the teacher and the rest of the pupils in the class.

To give the pupils a good start of the project, we have had numerous discussions of how the start page should be, and which role it should play. It ended with a web-site providing an introductory preamble to the theme of the project with some provoking elements like "why don't Norwegians eat dogs?"

Figure 1 shows the start page of 2001. Each of the pictures in the collage is a link and leads to a short video, audio file or text. Links are provided at the bottom of the screen to material prepared by content.
providers participating in the project (described in the next section).

Net-based content

Pupils normally define the problem areas of their work in groups, not necessarily focused on traditional subject boundaries. We observed that they (11 - 15 years) often had problems finding good and relevant content. Their sources were often very ad-hoc, and much of what exists is in English and often written for adults, see (Ludvigsen 01). It also appears to us that the material often supports the pupils' problem areas very poorly. We found a need for more material that is more available to the pupils in language, in actual themes and so on., without being a study book on the net.

Norwegian schools are using the Internet intensively in project work. They combine this with printed materials like study books, lexical books etc. Printed materials are usually very fact oriented and often appear to give answers to all relevant questions. Our opinion is that existing syllabus books often discourages rather than encourages discussion among the students and close subjects.

The Internet on the other hand is completely open. Here you find lots of mainly textual material, but the relevance, organization and language is often in a form not suited for children and project work. There are some exceptions, but in the amount of relevant material in Norwegian was found to be limited.

We therefore asked our content providers to try to develop the next generation net-based curriculum as open learning sources but well coordinated and targeted on “Norway as a multi cultural society” with main focus on food and culture – food and religion. The material was developed according to the following guidelines:

- We would have rich media content — text, pictures, audio, video and web pages.
- The content should be directed towards stimulate curiosity and discussion and not an accumulation of facts.
- Texts should be concise, structured to appeal to intuition, and should not follow a book like structure.
- Content from each of the three content providers (The National Library in Norway, The Norwegian Broadcasting Corporation and Aschehoug, a large Norwegian publisher) should be structured to support the materials provided by the others within the selected subject and should be mutually linked.
- All content should be available in a web-browser.
- In addition to the content providers services, audio, video and pictures should be available for editing and manipulation by the students.

Project tools

In project work, the pupils are producers. Learning takes place as an integrated and iterative process of a number of tasks; Searching (Internet, books aso.), collecting, editing, creating and merging. This normally requires several computer tools to support the students' various work processes.

In the first field trial (of three) in LAVA Learning see (Ludvigsen 01), we used a tool called Syncrolink, see (Syncrolink), in combination with the MS Frontpage html editor and MS Internet Explorer. Syncrolink is a tool that allows the user to annotate videos with hyperlinks to web pages. In the trials, the pupils used Syncrolink to see the video, remove the parts they didn't think was relevant and add links to web pages they had created or that was found on the Internet. Their work process evolved to: Find the interesting places to put links in the video (using Syncrolink), create or find web-pages that cover the issues being discussed (using Internet Explorer or FrontPage), store these web-pages and finally connect the links using Syncrolink.

The problem with this mode of work appeared to be that the students lost track of their contexts and hence that the different parts of what they produced did not harmonize very well.

Another problem that was observed in this first trial was that the children lacked a placeholder for interesting material they came across on the Internet. Adding the URL’s to the Favorites list in the browser only solved the problem on a specific machine. In cases where the pupils used different computers for content collection, they had problems transferring correct URL’s. Solving the problem involved writing down the URL or using a third tool to type it in, and store this on a networked disk.

In studying the pupil’s work we were convinced! Tools can never be neutral in this context. Inappropriate tools will easily distract the pupils' attention. Our opinion is that supporting a good working process is the best way the tool can contribute to good learning processes.

As for MS Frontpage, results (we took lots of video of the pupils during the project work) show that the pupils spent lots of time discussing the appearance of their web pages rather than discussing the content and subject matter.
In collecting preferable properties for a project tool we also wanted the ability to handle all media types in a transparent manner being it net-based or locally produced. Within the actual subject of the pupils project work, the Norwegian Broadcasting Corporation and the National Library had lots of relevant video material that they wanted to make available over the Internet. They wanted to experiment with new net-based services targeted for schools. TV is quite a different medium from video on the web, and TV programs are self-contained and have a longer duration than acceptable as part of a multimedia presentation. We needed to provide mechanisms for the children to include only those parts of the video that were relevant to their field of inquiry.

Experience from early trials of the LAVA project, showed that when students edited a selected video from 30 to about 5 minutes, the exercise gave them a much deeper grasp of the subject matter in the video. In later trials we wanted to preserve this ability.

Permissions to do this editing of copyrighted material were needed and given by the content owners. We wanted to test our earlier observations that the editing process led to better understanding of the video content. To avoid copying and changing the original video material, and avoiding having to copy and handle large video files, the video editing needed to be carried out on streamed video with caching capabilities.

We started looking for a convenient project tool with a clear focus on the need for support of the pupils work processes. Having evaluated easily available tools like MS PowerPoint with MS Media, Macromedia Dreamweaver, Real and others, we found that none provided good support for our requirements. Having the resources of developing our own tool, we decided to create what became the Slime tool shown in figure 2 and 3.

The main approach behind Slime was to provide a set of canvases or scenes where all media types could be collected and edited. Since the scenes needed to handle both static and time-varying media types, we decided to tag all media types with time tags. This meant that in playback mode, a text, a web-page and a picture would all be assigned a time slot when each object was displayed on the canvas, and a time where it each object would disappear.

In Slime content objects are displayed in parallel or in sequence or overlapping in time during playback of edited material. The contents of a "scene" can be played as a synchronized whole. When all media objects in a scene have been played, the tool jumps to the next "scene".

To navigate between the scenes of a project, users can use both the scene graph, the navigation box to the lower left, and the overall timeline shown on top of the tool. The scene graph is a graphical display of the object names and structure of scenes.

Students can easily switch the search modus of the tool by clicking on the switch button. The search mode allows the user to search the Internet using a standard web-browser, or collect local files or search in given content providers' databases for annotated material. Interesting materials found can be collected and included in a given scene. Material collated in this fashion can be thereafter edited and synchronized with the other content objects.

Figure 2: The Slime tool in production modus
A special object model underlying the Slime tool that makes it possible for content providers to control content distribution and use after it has left the server. These security, IPR and copyright issues are beyond the scope of this paper, but are documented in (Diesen 00).

The snapshots in figures 2 and 3 indicate some of the functionality of the Slime tool. For a more detailed description, please see (Slime).

Results and discussion

To document the school trials, researchers have been in the classrooms, and about 40 hours of video of pupils working together using the Slime tool are available. The pedagogic results will be comprehensively documented in papers by other researchers in the LAVA Learning project, and will be available on http://www.nr.no/lava/lava-le/ as they are published. We will focus here on some of the content and tool issues.

We found that the Slime tool was able to support the entire project oriented learning process of the pupils. Many of the pupils started their production by creating a structure of empty scenes. This worked as a way of storing their common understanding of what their project would result in. Project structure was frequently revisited and discussed during the project work. This showed us that this kind of mutable structuring element provided good work support. It generated considerable discussion about the organization of their material for example by serving as a focal point to identify what was lacking and so on.

Despite the excellent support of student work processes, we clearly saw that Slime is a poorer presentation tool than PowerPoint. We had observed problems with timing of the display of text boxes. This indicates the need for a "proceed" button or a revision in our approach to the time model.

What we also found was that material made available directly into the project tool worked well and was used to some extent, but the video material not was sufficiently annotated. The pupils had to go through what they assumed to be relevant in order to evaluate it, and the annotations did not give a sufficiently accurate description of video content. Lots of pupils ended up omitting the use of video, or just using privately produced video. In the next field trial (the third and last of LAVA Learning), we will have to annotate the videos with a higher granularity. This will ensure that search results will turn up only the relevant parts of a video.

We also observed a problem with content resources in general. The problem focus of the different project groups of students was very broad. Teachers will either have to restrict focus, or huge amounts of content must be made available. Students found lots of material on the Internet on relatively ad hoc web sites, and the content was used relatively uncritically with regard to the sources. It is obvious to us that there is a pressing need for more content, and an educational emphasis in critical evaluation of sources available on the Web is very important.
Conclusions

We feel that we have managed to combine research in the three areas of pedagogy, content production and technology to create a good working learning environment using a project based learning approach. The main emphasis is on the pedagogy, which defined the framework for a project tool that would support effective learning. The issue was to keep student focus on the subject matter of the project and not on the underlying technology.

Our observations from field studies indicate that a specially designed project tool like Slime enables students to keep their focus on the subject matter to a much greater extent than the traditional off the shelf tools. Integration of search and production facilities turned out to be important to the learning process.

The content providers of LAVA Learning gave access to their raw material, which enabled us to link it directly into the project tool of the pupils. This turned out to be successful, but the amount of available and structured content for educational needs will need to be provided to keep up with demand for electronically available material. It is of great importance to get reliable sources of material available on the Internet for the children working with an approach like project based learning.

Do children learn better in this way? This really is a question with no simple answer. What we have seen is that motivation increases a lot. Some children would hardly leave school. On the other hand, we believe that a good learning result requires well functioning project groups and a good teacher. The teacher needs to help the groups in finding good problems to work with and in testing the relevance and quality of the material they use.

Acknowledgements

LAVA Learning is a project with many contributors from different fields. The learning arena and the Slime software is developed with the combined effort of many school teachers, college teachers, content providers and researchers. We would like to specially acknowledge the contribution from second professor Sten Ludvigsen from InterMedia, University of Oslo, who has lead the pedagogical research and helped us extensively. The same is the case for the researchers Dag Diesen and Asbjørn Oskal from NORUT-IT in Tromsø, Norway, who have been developing Slime with us, and Ph.D. student Anders Kluge at the University of Oslo. Without you, this project wouldn't have been possible. Our thanks also go to the Norwegian Research Council (NFR) that provided funding for the project.

Abstract
This presentation provides guidance on the issue of universal web accessibility for individuals with physical challenges who need accommodations to fully participate in the electronic world. Four categories of information facilitate understanding the complexity of the issues. These categories are:

- U.S. legal mandates;
- International accessibility policy and legislation;
- Resources and information; and
- Web site accessibility validation.

These four are explored in depth and provide the tools for meeting today’s challenges. As the Web evolves, new accessibility issues will emerge. Once you think you have it figured out, it will change, requiring continual self-study to keep abreast of the how these changes effect your situation. Helpful resources can be accessed from the following site: Http://www.e-linkagesglobal.com

Introduction.
This presentation provides guidance on the issue of universal web accessibility. Lack of information concerning web accessibility not only contributes to the digital divide, but can lead to serious legal problems as well. Lawsuits can arise because of U.S. legislation that required all web sites receiving federal funds to meet accessibility directives by the spring of 2001. The goal of this paper is to provide clarification of the accessibility statutes and offer resources and information to assist in successfully developing accessible web sites.

The circular process of comparing and contrasting information from the Internet, expert testimony and personal expertise were the primary components fueling the engine of this qualitative inquiry. It goes without saying that constant and rapid change makes it extremely difficult to study any phenomenon on the Internet.

Many web developers are ignoring the accessibility issue or just do not know how to make their sites universally accessible. They are bewildered in the face of the vast amount of information available on applying accessibility techniques to the design of their web sites.

Four categories of information facilitate understanding the complexity of the issues. These categories are:

- U.S. legal mandates;
- International accessibility policy and legislation;
- Resources and information; and
- Web site accessibility validation.

These four areas provide the tools for meeting today’s challenges. As the Web evolves, new accessibility issues will emerge. Once you think you have it figured out, it will change, requiring continual self-study to keep abreast of the how these changes effect your situation.

The Legal Mandates for Accessible Internet Sites
The Americans and Disability Act (ADA), which was signed in 1990, prohibits discrimination “on the basis of disability in employment, programs and services provided by state and local governments, goods and services provided by private companies and in commercial facilities.” However, the ADA doesn’t just apply to the physical world. Waddell
(1998) points out that according to the Justice Department, the ADA also applies to cyberspace. In an opinion letter dated September 9, 1996, The Justice Department stressed that covered entities under the ADA are required to provide effective communication, regardless of whether they generally communicate through print media, audio media or computerized media such as the Internet. Covered entities that use the Internet for communications regarding their programs, goods or services must be prepared to offer those communications through accessible means as well.

Section 508 of the Rehabilitation Act Amendments of 1999 (http://www.access-board.gov/sec508/nprm.htm) provided the basis for the Electronic and Information Technology Accessibility Standards, enacted August 7, 1998. "Effective (two) years after the date of enactment, any individual with a disability may file a complaint alleging that a federal agency fails to comply with section 508 in providing accessible electronic and information technology."

Carnevale (1999) notes: "As colleges and universities expand their distance-education programs, they are finding that they must include the virtual equivalent of ramps when building their website. Higher education institutions know they're obligated. "It's not that web site creators are ignoring the accessibility issue," says Jane Jarrows, president of Disability Access and Information. "It is that they don't always realize how important accessibility is." While the U.S. Department of Education's Office for Civil Rights (OCR) has specific guidelines for compliance on traditional campuses, the agency has not yet issued accessibility rules for online education.

United States Legal Cases Related to Education

According to Waddell:

Not surprisingly, web accessibility issues are now being faced by educational institutions. Library reference services are being transformed by the efficiency of Internet access to information systems and search engines. Professors are teaching long distance learning courses over the Internet and even if a student is physically in class, homework assignments and resources are being posted on class homepages. Yet, even if a library terminal has assistive computer technology installed for students with disabilities, Internet research by students with disabilities is not possible with inaccessible web page design.

A blind student from Long Beach California filed a complaint to the Office of Civil Rights (OCR). The university provided OCR with a voluntary resolution plan, which resolved the issues raised in this case. The plan included the following commitments:

1.) Develop and implement a systematic method for ensuring that the issue of accessibility to persons with disabilities, particularly blind persons, is taken into account when colleges purchase computer software and hardware.

2.) Develop and implement a systematic method for informing campus employees who design/select web pages for use by students to make sure the web pages are in accordance with principles known to maximize accessibility to users with disabilities, including visual impairments.

...(T)he issue is not whether the student with the disability is merely provided access, but the issue is rather the extent to which the communication is actually as effective as that provided to others. Title II (of the Americans with Disabilities Act of 1990) also strongly affirms the important role that computer technology is expected to play as an auxiliary aid by which communication is made effective for persons with disabilities" (Pages 1-2, 1996 Letter; 28 C.F.R. 35.160(a)) (Waddell, 1998 citing Brummel, 1994).

In further clarifying what is meant by “effective communication,” OCR has held that the three basic components of effective communication are “timeliness of delivery, accuracy of the translation and provision in a manner and medium appropriate to the significance of the message and the abilities of the individual with the disability” (Page 1, 1997 Letter) (Waddell, 1998, citing Brummel, 1994).

On June 25, 2001, the accessibility requirements for U.S. electronic and information technology took effect under Section 508. This law mandates that this technology be accessible according to standards developed by the Access Board, which are now part of the federal government’s procurement regulations.

Section 508 and its enforcement provisions apply to products procured by U.S. federal agencies after June 25, 2001. This law relies heavily on the procurement process to make sure there is compliance with the new standards. Compliance with the standards is required unless it would pose an "undue burden"—as defined in the standards—or if no complying product is commercially available. The law permits individuals with disabilities to file a complaint with the appropriate federal agency concerning access to products procured after the effective date.

**International Accessibility Policy and Legislation**

Accessibility issues are considered to be one of the “target areas for equal participation” at an international level. Late in 1993—at the infancy of the World Wide Web—the United Nations General Assembly adopted the Standard Rules on the Equalization of Opportunities of Persons with Disabilities [1]. Rule 5 of the Standard Rules addresses accessibility in terms of the physical environment and with reference to information and communications services. Among other points, Rule 5 recommends: 'States ... develop strategies to make information services and documentation accessible for different groups of persons with disabilities.'

Although not a legally binding instrument, the Standard Rules represent a strong moral and political commitment of governments to take action to attain equalization of opportunities for persons with disabilities. The rules serve as an instrument for policy making and as a basis for technical and economic cooperation. In the past few years, a special rapporteur appointed by the U.N. Secretary General to monitor the implementation of the Standard Rules has encouraged governments to consider accessibility of information and communications services within their country’s social development policies.

The unique governance structure of the Internet makes it difficult, if not impossible, for a country to impose accessibility legislation on its own citizens. For example, it is not easy for one government to impose penalties for poor accessibility in a web site of one of its own citizens if the web site is hosted in another country. Governments have used either policy or limited legislation in an effort to ensure that public information is an accessible public good.

Policies that encourage accessibility—stating its benefits to the producers and consumers of information—are used by most of the early adopters of the importance of information accessibility. These policy/guidelines can only implement minor penalties such as the notoriety
of non-conformance. Australia, Canada and Portugal have issued policy statements, and have mostly limited policy application to their own federal governments.

A good example of a clear and concise policy statement comes from the "Guide to the Internet" of the Government of Canada. It states:

"Since the end user cannot count on either standard technology or helping devices to ensure access to information on the [World Wide] Web, the onus is on the web page developer to deliver the message in a way that allows everyone to benefit.

"It is every Canadian's right to receive Government information or service in a form that can be used, and it is Government of Canada's obligation to provide it."

Only the U.S. has, so far, turned information accessibility into legislation. It does so using both “push” and “pull” regulations. "Push" regulations—such as Section 255 of the Telecommunications Act of 1996—require industry to consider accessibility. This type of regulation is, however, only effective in production of accessible products such as kneeling buses and accessible teller machines. It is difficult to regulate delivery of online information using “push” regulation because World Wide Web information is available globally, and there are many countries that do not consider information accessibility an issue.

Section 508 of the Rehabilitation Act is an example of "pull" legislation because it requires that the government purchase accessible products, but does not require that industry produce them. This provides a market pull to industry. Obviously, industry prefers pull regulations to push regulations. In practice, Section 508 may also be more effective because suppliers stand to lose major federal contracts if they are perceived not to adopt corporate accessibility policies. By imposing accessibility regulation on its own ranks, the U.S. federal government is hoping that corporations will adopt accessibility policies as a matter of example and as a sign of good corporate citizenship.

The European Union seems convinced that “pull” regulation and standardizing on WAI is their best option. In its Europe Action Plan, the E.U. provides a special section titled “e-accessibility: Participation for all in the knowledge-based economy.” This action plan optimistically targets the year 2002 as the deadline for all member countries to make their federal websites follow the WAI Content Accessibility Guidelines.

In Canada, federal websites have mostly complied with the Treasury Board Secretariat's Common Look and Feel (CLF) Guidelines. The successful implementation probably makes Canada's web sites the most accessible among industrialized nations. But the Treasury Board is not satisfied. The CLF Guidelines are currently being used in the formulation of legislation similar to Section 508, and with a compliance date of December 31, 2002. The difference between U.S. regulations and the Canadian and E.U. regulations is that Canada and the E.U. are adopting the W3C Web Accessibility Initiative as a reference material to keep with new technologies and developments. This move will likely be the same approach as other countries determine how, if ever, they formulate information accessibility policy.

Unfortunately, many countries may never have to deal with web accessibility for mostly economic reasons. One reason is that country priorities for information and communication services will naturally begin with the telecommunications infrastructure and the cost/benefit analysis of various platforms. For example, the e-Mexico project concentrates on making telecommunications facilities available to the rural areas, and the term accessibility is used to refer to the access of these facilities.
Another reason web accessibility might not be adopted is that in countries where labor costs are low, care giving for persons with disabilities is the norm, and independent living is not common. Caregivers can be asked to provide other services such as reading books and online information.

**Verification of Web Site as Universally Accessible and Related Services**

Web pages need to be validated to ensure they meet the minimum requirements for universal accessibility. There are two major validation services—available free online—which evaluate web pages and help identify potential accessibility problems to correct. The first is Bobby, which is part of the Center for Applied Special Technology (CAST), a non-profit organization, whose mission is to expand opportunities for individuals with disabilities through the development of innovative technology. The Bobby validation system is simple to use to validate a web site. The web site URL is submitted by entering the information onto the web page and then clicking a submit button. [http://www.Cast.org/](http://www.Cast.org/)

The process for obtaining the report is easy. Copy and paste the URL to insert into the verification program. Copying and pasting keeps from making a typing error. Tip: If a Windows-based computer is used, select/highlight the URL and use “Ctrl” and “C” keys to copy the URL and then “Ctrl” and “V” keys to paste the URL to the address box. Then submit.

Web sites should have at least a *Priority One Accessible* rating. When users get feedback from the site, they will be able to see the entire page. Tiny question marks by the images means for users to check their information manually—this will not stop those from getting validated. If major problems are experienced, a question mark appears by each image.

W3C Validation. The second major validation site is W3C’s HTML validation service, a free service that checks documents like HTML and XHTML for conformance to W3C recommendations and other standards. [http://validator.w3.org/](http://validator.w3.org/)

Approval Icon. The NCAM accessibility icon was selected from 17 symbols as a Web Access Symbol for people with disabilities. Web masters can use this to denote their site contains accessibility features for disabled users. The symbol should always be accompanied by its description—a globe, marked with a grid, tilts at an angle; a keyhole is cut into its surface—and alt-text tag,. This image was created by Stromship Studios of Boston. There is no charge to use this symbol, and it may be used in electronic or printed form. It can be copied from the NCAM web site and pasted it into a document. [http://ncam.wgbh.org/accessncam.html](http://ncam.wgbh.org/accessncam.html)

**Conclusions**

"The difficulties of studying the Internet can only be described in the present moment due to the constant state of change on the Internet" (Rizia, 1999). The future will hold many exciting technological innovations, making computers adapt to individuals rather than the reverse. Technology that allows access to computer resources for a person with disabilities is known as adaptive technology. These "electronic curb-cuts" are a combination of hardware and software. The challenge is making adaptive technology part of any base configuration and making all components work in a seamless fashion. This will increase the access to computers and applications without making major modifications.

When designing for the Internet, a global approach needs to be considered. As of now, the U.S. is the only country that mandates accessibility for anyone doing business with the government. Of course, that includes most higher education institutions. Meeting accessibility guidelines for most situations means adding descriptive tags to any image and text links for audio or video files. Anyone, anywhere can use the Bobby site to check for these simple things. Having
accessibility sites makes good economic sense as the number of individuals with disabilities on
the Net—who could emerge as consumers of vast numbers of products—continues to increase.

Implementing a Quality Management System in E-education

Jill Fresen
Department of Telematic Learning and Education Innovation
University of Pretoria, South Africa
jfresen@postino.up.ac.za

Lesley Boyd
Independent QA Consultant, Johannesburg, South Africa
lboyd@mweb.co.za

Abstract: Quality is an elusive and ill defined concept. We have become accustomed to associating quality with fancy features, high prices, zero defects and conformance to specifications. How do we interpret Quality in the field of higher education in general, and E-education in particular? In the field of higher education, we speak of "best practices", "quality learning interventions", "design standards", "quality instructional design", "quality services and products" etc. Although there is a fair amount of literature on quality management in higher education, there appears to be little which applies the principles of Quality Assurance and Quality Management in the field of E-education. This paper describes the implementation of a formal Quality Management System in E-education at a tertiary institution in South Africa.

Background

The Council for Higher Education (CHE) in South Africa is a statutory body established by the Higher Education Act of 1997 to advise the Minister of Education on all matters pertaining to higher education. The CHE is responsible for establishing a quality assurance system for higher education through the Higher Education Quality Committee (HEQC), which was constituted in March 2001.

There is a real need for ETD (Education, Training and Development) practitioners to research the implementation of QA systems and to contribute to the work of the HEQC. The founding document of the HEQC states that "The HEQC is committed to a quality driven higher education system that contributes to socio-economic development, social justice and innovative scholarship in South Africa" (CHE, 2000, p.5).

Context

The Department & Telematic Learning and Education Innovation (TLEI) is a service department, which was established at the University of Pretoria, South Africa, in 1997. We provide support to academic staff members who wish to embrace innovative learning models, including computer-assisted assessment, multimedia, web-supported learning, interactive television and various other delivery alternatives and combinations. We provide faculty and student training in online learning, as well as technical support.

Research Brief

This project focuses on the quality of the products and services offered by the E-education division of the Department of TLEI. The research brief of this study is to implement a Quality Management System (QMS), which will formalise processes, procedures and measurement instruments.

A Quality Management System (QMS) is a way of formally ensuring that an organisation is consistently in control of the product or service which it provides to its customers. The British
Standards Institute (BSI) defines a QMS as “the organisational structure, responsibilities, procedures, processes and resources for implementing quality management” (Boyd, 2001). Documenting a quality system demonstrates how each of the aspects interacts to ensure success in improving the efficiency, performance and cost effectiveness of the organisation. A QMS should not be perceived as separate from the way ‘things are done around here’, but a way of evolving better and better business practices and a part of normal everyday routines.

Although a conscious decision not to seek certification to ISO9000 standards has been made at present, it is useful to review the provisions of ISO9000 both in application to education, and to software systems development, so that the system is suitable for refinement and auditing to ISO9000 standards in the future, if required.

For the purposes of the QMS, we define our “customers” to be lecturers and students, and we describe our “products” as learning experiences.

Quality Management System – progress so far

We began by documenting our intuitive ideas for monitoring and evaluating the learning experiences we design and develop. Our Instructional Design “toolkit” consists of design standards for multimedia, video and web-based products, QA checklists used to evaluate prototypes, guidelines for screen design and other technical functions, as well as client service satisfaction surveys.

Our Project Timeline reflects the traditional ADDIE instructional design model, namely Analysis, Design, Development, Implementation and Evaluation. Following these five stages, we have defined our overall processes to be: A: Initiate Education projects; B: Manage Education projects; C: Design and Develop Instructional Materials; D: Implement learning experiences (products); E: Evaluate learning experiences (products). These five processes are broken down into a total of 17 procedures, each represented by a box in the project timeline.

We conducted introductory QA training workshops, which were attended by all staff members in Eduction. Process diagrams indicating the suppliers, customers and their requirements at each stage have been used to gain insight into the five processes and how they may be measured effectively. The importance of measurements in completing the feedback loop is vital, and these are yet to be defined.

We have formulated a Quality Policy, which is an essential component of a QMS. The policy reflects our commitment to fitness for purpose, client satisfaction, cost effectiveness and continuous improvement of all our processes and functions. The formal QMS will reside on the departmental intranet, in order to facilitate access to and control of documentation.

Conclusion

This is a work-in-progress project, which contributes to the field of Quality Assurance in Higher Education, and Education in particular. It will provide input to the HEQC in South Africa, in their brief to establish a framework for Quality Assurance in Higher Education. It will provide insight into the practical dilemmas of implementing a formal Quality Management System in Education at a tertiary institution.

Participatory Design, Problem Solving and Community Involvement in Two Different Learning Communities

Robert S. Friedman, College of Computing Sciences, New Jersey Institute of Technology, Newark, NJ 07012

Fadi P. Deek, College of Computing Sciences, New Jersey Institute of Technology, Newark, NJ 07102

Abstract

A collaborative software development project designed to maximize the skill sets and interests of school children and teachers, educational software technologist and researchers, and college undergraduates is presented. The work brings together elementary school children with college seniors and technology consultants to implement a problem-solving methodology within a collaborative environment to design, develop and implement a multimedia software application that enhances the spatial orientation abilities of children and puts the programming, interface design and multimedia systems capabilities of college students into action. This effort in project-based learning offers young students the opportunity to learn mapping skills, problem-solving techniques, and participatory design methods while planning and conducting virtual tours of their city.

Introduction

Familiarity with geography, the science of space and place on the Earth’s surface, helps people visualize and understand their home and orient their relationships vis-à-vis other cultures and environments. Maps help to show children where they are, where they’ve been and where they can go, while creating a sense of belonging to a community, a history and a path to the future. The urban environment, in particular, is populated with many young students who do not often perceive their world beyond the boundaries of their immediate neighborhood.

We describe here a software development collaboration project designed to maximize the skill sets and interests of elementary school children and teachers, educational software technologist and researchers, and college undergraduates. Through the implementation of project-based learning, problem-solving and participatory design methodologies, and community involvement, software containing interactive video, calculation programs and spatial orientation tools offers 4th- through 6th-grade students in Newark, New Jersey the opportunity to learn mapping skills while planning and conducting virtual tours of their city.

Cognitive Development, Spatial Orientation and Technology
Learning theorists have articulated unique developmental predispositions for different kinds of learning. David Sobel (1998) states that between ages five and seven, children start to move away from home and parents and explore the natural world. From ages seven to eleven, children are predisposed to merging with nature and making geographic sense of the world around them. Although computers cannot replace the human contact and feedback that only a teacher can provide, they are tools that can be used to significantly enhance students' educational experiences at a time when children have a propensity to explore. Through the process of participatory design (Druin, 1999), 10-year old students have an equal, if not greater stake in the development, testing, refinement and use of the software as compared to the college students who are interacting with the youngsters at each stage and step of the software development process.

Software companies have developed a wide range of software applications geared to geographic inquiry and map making. The current strategies used in mapping software programs permit students to be active mapmakers. Neighborhood Map Machine, Trudy's Time and Place, Carmen Sandiego, Where Are We, Map Makers Tool Kit, Geo Safari – all introduce geography skills to students grade 4-8, geared to providing geographic discovery and knowledge. What these programs cannot offer, however, is any significant or concrete local context for the user. Moreover, educational software applications generally do not satisfactorily support the urban environment. Their symbols are suburban in orientation, and many of their activities use rural landscapes as a backdrop to learn navigating skills. However, children often do not have an opportunity to explore their neighborhoods. Urban lifestyles sometimes include dangers in neighborhoods and deplorable conditions of many buildings, causing parents to be reluctant to have their children explore on their own.

We've developed a partnership among students and faculty at the New Jersey Institute of Technology, Little Bytes, a technology-integrated curriculum development firm, and St. Philip's Academy, an independent elementary school in Newark, to serve as the foundation for a comprehensive multyear program in multimedia learning systems that brings college seniors studying software engineering and multimedia design together with elementary school students and teachers in an effort to provide community-based educational software that introduces children to the landmarks and cultural facilities of Newark through the collaborative development of mapping skills instructional software. A major goal of the program is to build on the participatory design model of software design, articulated most clearly for application in an educational environment by Druin (1999), and a problem-solving methodology that has been successfully implemented at NJIT and in four Newark public high schools (Deek, 1997; Deek & Friedman 2001). We are testing the hypothesis that integrating these two models will promote positive change in the academic climate of classrooms by incorporating teachers, students and skilled college-level software engineers to create educational multimedia applications that accommodate the specific needs of the younger students, provide teachers with design-level access to appropriate instructional materials and educational technologies, and give youngsters hands-on experience in the design, development, testing and use of computer software tools.

Our project began with Little Bytes, a client of NJIT's business incubator providing the content specifications to begin building the software application. The NJIT/Little Bytes collaboration has opened the door to increased involvement with community-based and civic organizations such as the Newark Museum, Newark Bears baseball team, New Jersey Performing Arts Center, the Newark Housing Authority and the Newark Department of Engineering, all of whom have contributed to the development of a mapping skills software application that is focused on Newark's neighborhoods and landmarks. Having already placed several college students, earning service learning credits, at St. Philip's Academy, where Little Bytes serves as educational technology consultant, we were well positioned to expand our involvement to include a small class of seniors to focus on a specific outcome.

**Project Implementation**

During the spring 2002 semester, NJIT seniors majoring in multimedia information technology, information systems and computer science, were more enthusiastic to be involved in this innovative project. The college students' educational experience is project-based, as it moved them out of the lecture hall and into the community and the computer lab as they worked with learning systems researchers, 4th-6th
grade students and educational technology consultants to implement a software design that was created collaboratively among St. Philip's Academy 4th grade school students, their teacher and Little Bytes. The software's three major components begins with a series of fun tutorials facilitated by an animated character, during which the user learns basic geography skills; putting those skills to use as they conduct four searches throughout different locations in Newark, and finally being able to design virtual tours of the city by building efficient routes between landmarks that are in video format.

The protocols of the project are oriented to maximize a problem-solving methodology found effective in computing, mathematics and composition courses at the pre-college and college levels (Deek & Friedman, 2001), combined with Druin's approach to software engineering (Druin, 1999). Children's interaction with technology expands beyond their end-user status and into the conceptual design, development, usability testing and debugging phases as well. By involving the children, we supply an alternative method of software design, development and evaluation, one that is accessible to our end users, the elementary school students. Through the use of visually oriented software design and increased opportunities to team children, teachers and software engineering students, educational researchers and software designers in the development of new applications, software evaluation becomes the province of all the participants.

Application development through participatory design has three main goals: to develop integrated learning environments that support visual and verbal literacy; to encourage student centered learning; and, to develop methodologies that offer a better understanding of what children want and need when using technology. The program provides a combined laboratory and classroom environment in which participants design, develop, test and refine software tools intended to inculcate spatial awareness and mapping skills while also attaining positive results with students.

Problem-Solving

Through participatory design, there are extended interactive discussions among teachers, students and software engineers during each phase of software development. We began with a meeting of all the people involved: the 4th graders, their teacher and principal; the college students and their instructor, two representatives of a community based youth group, Do Something Newark; and two educational technology consultants from Little Bytes. After explaining to the youngsters briefly what we had in mind, the children were asked to describe and draw a picture of a character that would act as their guide through the computer game. The college students formed several groups: graphical user interface designers, database and systems programmers, videographers and 3D designers, and each began to storyboard specific components of the intended product.

There are three major components. Section 1, Navigator, consists of 11 skill building interactive exercises that teach basic map reading skills. Here, an animated character that acts as a guide, Mapper, is introduced. Section 2, Mad Mysteries, presents three scenarios in which students find answers to clues offered in each to solve mysteries that take place in Newark. They are awarded certificates of proficiency that allow them to move on to the final component, Section 3, Create a Tour. The children are given a problem to solve: how to structure a tour of Newark for four different groups of tourists, all with different time constraints as well as interests. The skills garnered in Section 1 and tested in Section 2, are applied in Section 3. After two weeks of preliminary design, the college students settled on Macromedia Flash as the animation and movie creation software best suited for sections 1 and 2, and Adobe Digital Video Suite served as the main technology behind section 3.

Employing a consistent methodology that is common to all the participants and able to be documented added to the sense of partnership among the participants as they shared ways to solve problems specific to the areas that each encounter. Bringing theory into practice, as Filho (2001) suggests, demands that a process architecture be used when students are engaged in complex software engineering projects such as the project described here. We used SOLVEIT, which is such an architecture, and has been successfully employed in high school and college settings. (Deek & Friedman, 2001) The SOLVEIT environment is collection of tools supporting a six-step process for problem solving and software design and implementation. These steps are: formulating the problem, planning, designing, and translating the
solution, and finally, testing and delivering the product. The combination of a participatory design approach and SOLVEIT as a software engineering methodology produced a highly accessible interactive software application. NJIT students used applications such as Flash, 3D StudioMax, Adobe Digital Video Suite, as well as C++, Java and Access to provide the younger students with a game-like learning environment. This combination of methodologies and tools not only broadens all the students’ educational experience, but also provides a more meaningful context within which to integrate the knowledge and skills they have garnered.

Student Response

While the college students were initially hesitant to break free of their traditional classroom environment, they were quick to appreciate the benefits of working within the structure provided by SOLVEIT as well as those that problem-based learning experiences offer, particularly when the solution to a problem takes the form of interactive software, and the design and development of that software is based in the methodology of participatory design. Ritika, who was responsible for the scaling activity in the Navigator group, used Flash 5 because the class had agreed on doing most of the project with it. Also, it was something new to me, and I wanted to learn it. I tried to think of the kids’ demands first when I was making this, so I tried to make it as fun as possible. I put in animations, and will put in sounds, which I think they will enjoy. From the last meeting with the kids, I could tell they wanted something very challenging with degrees of difficulty, but I am not sure how to incorporate that into my part of the game. (Instructor’s notes)

Marc was part of the audio/video team responsible for the planning, shooting, editing, and integration of video footage and voice-overs. In a mid-semester report he noted,

The recent visit by the St. Philip’s students to our NJIT lab led to the continued development of software segments that have thus far been pieced together. The students’ ideas reflect their upbeat attitude toward the city of Newark and their role in the project. An example of their input during this meeting was the idea to change the background color at the welcome screen from a black night to a more optimistic daytime. Jerri, Ursula [of Little Bytes] and AJ [Zenkert, the 4th grade teacher] have all been a big help. Ursula is good at clearing up confusing development issues between Jerri and our NJIT class. I look forward to our future collaborations. (Instructor’s notes)

Rajesh, who in addition to the credits is responsible for several of the Navigator components, used Macromedia Flash, Adobe Illustrator, Microsoft Paint, and Microsoft Image Composer as development tools.

These were chosen for their development capabilities and ease of use. On average, in addition to class time, I spent about 5 hours a week on the project. Initial progress was slow because of the learning and investigating time involved in starting the project. Meeting with Jerri, Ursula, AJ, and the St.Philip’s kids proved that the users need a fun, challenging, and educational application. (Instructor’s notes)

Gosia & Tim began their work by developing the introduction sequence for the software.

We used traditional storyboarding and drawing techniques to develop the intro Space animation. We tried to make an entertaining and fun animation that hoped to show the kids from St. Philip’s their perspective by traveling from space, down through the solar system, into New Jersey. Music was added to give a little flavor to the work using a hardware synthesizer, along with other software. Working in the studio environment with all the very diverse people was unarguably the best experience I have had since being at NJIT. (Instructor’s notes)
Nainsi and Parag found that,

This class has given a wonderful opportunity very close to the real world without entering a REAL world. Our project was mainly created by Flash; I have learned lot about Macromedia Flash and its implementing capabilities. Drawing with details and putting every piece together is sometimes tedious. But overall it is fun. Our discussions among ourselves, Jerri and the kids have shaped our requirements tightly. I really like the involvement of kids in our project, as I find them smart is noticing things and accurate in demanding what exactly they will like to see. What I don’t like sometimes is not having a set rule, not knowing what actually is needed until it is done halfway or all the way. But I guess that is part of learning, and I don’t have many complaints about that. (Instructor’s notes)

St. Philip’s Academy students and teachers have also benefited from this project in many different ways. The current Social Studies curriculum does not contain many lessons about mapping and map usage. Quality supplemental mapping skills material are not easy to find, particularly material that involves the type of mapping that is most pertinent to urban students’ world: the city. When students understand how to use maps and concepts of scale and distance, they have skill sets that can be applied in subject areas such as history, politics, wars, migration, and immigration.

For the students, the opportunity to participate in the development of software is invaluable. Being a part of a team, whether it is a sports team or a debate team, teaches children about working together, solving problems, listening to others’ ideas, and communicating. Throughout this process, the students have had to use and improve all of these skills. What they did not realize was that they learned and reinforced many mapping skills without ever sitting through a traditional classroom lesson. The students were very eager and excited to be a part of the project, and they worked very hard to be helpful, honest and creative in the process. They began to understand that they could not have everything they wanted in the software, but that it did not hurt to offer ideas and attempt to help, with the hopes that their ideas would be used in the final product. The teamwork, brainstorming, and creative thinking that the students used during this process provided a wonderful challenge and learning experience for them.

During a recent usability testing session, 14 4th graders reviewed several components of the Navigator section, including a parade that asks them to measure distance and height, and assess whether a float will be able to pass under a bridge, a “walk in the park,” which tests students’ ability to orient themselves to shifting directions, and a “legend” exercise that asks students to identify icons and move them in their appropriate places on a map. Feedback was obtained concerning levels of difficulty, “coolness,” as well as descriptions of what the students learned. These results have direct bearing on the nature of the modifications the college students will do over the summer, but also suggest that we are on the right path, not only in terms of integrating software into the 4th grade curriculum, but also that involving the children in the design and development of the software has proven beneficial to the younger participants of the project. The majority of children found the software to be “cool,” the instructions clear and the navigation easy. There was a nearly unanimous call for the components to be more challenging, but at the same time, more children found the software to be fun than boring. When asked, “What did you learn while playing this activity?” ten of the 14 respondents answered, “How to measure,” while the remaining four replied, “Nothing.” When asked, “If you could change this activity in any way, what would you change?” about half answered, “Make it easy,” two said, “Make it more challenging,” and four did not respond. Generally, the students liked the interactivity and that the activities require concentration.

Conclusion and Future Work

Development and utilization of customized educational software empowers the teacher and takes advantage of rapidly emerging multimedia technologies. We expand our scope and vision by bringing together the classroom teacher, students, the business community, civic institutions with the universities to create technology integrated products designed to promote student-centered learning which serves the
community and ensures educational success of the child. The first version of City Mapping is designed primarily for 4th graders. It is our plan to produce a module for 5th and 6th graders as well during the fall 2002 semester. At the time, we will also expand our technology integration into the elementary school curriculum by implementing an international media sharing collaboration among students in Indonesia, Poland and Newark, with NJIT students building the infrastructure that will allow the exchange and collaborative development of music, art and narrative via the Internet.
Supporting the Application of Design Patterns in Web-Course Design

Sherri S. Frizell and Roland Hübscher
Department of Computer Science and Software Engineering
Auburn University, USA
{frizess, roland}@eng.auburn.edu

Abstract: Many instructors are expected to design and create web courses. The design of web courses can be a difficult task for educators who lack experience in interaction and instructional design. Design patterns have emerged as a way to capture design experience and present design solutions to novice designers. Design patterns are a widely accepted method of providing design support to software engineers, and they have been proposed to support designers of web-based courses. However, end-users' abilities to use design patterns are unclear especially since web-course design and computer programming are different activities. We present a methodology for supporting novices' use of patterns during web-based instructional design. This methodology consists of a pattern language for web-based instruction and a design environment that scaffolds the process of finding, selecting, and applying patterns to design problems.

1. Introduction

Design patterns provide a way to capture and present solutions to design problems and to facilitate communication among the many members of a design team. The use of patterns for design originated in the field of architecture during the late 1970s as a way to describe solutions to reoccurring problems encountered in architectural design (Alexander et al., 1977). The goal was to support both architects and the general public in designing quality towns, neighborhoods, and homes. Building upon this work, the concept moved into the software engineering discipline as a way to document design experience for less experienced software developers (Beck & Cunningham, 1987; Gamma et al., 1995). These patterns have since been used as an educational tool to teach computer science curriculum (Gelfand et al., 1998). Design pattern usage has also become a relatively new idea in the field of human-computer-interaction and educational technology to support designers in interaction and instructional design (Borchers, 2001; Frizell, 2001; Rossi et al., 1996).

The popularity of design patterns can be attributed to their ability to capture design experience and their concrete nature. Patterns are more flexible than static templates and more concrete than abstract guidelines. This suggests that end-users can better apply them to their design problems. Although the literature on design patterns makes claims to their effectiveness in helping novice designers, there is not a lot of empirical evidence with end-users utilizing patterns in actual design projects. The current research is from the area of software engineering, whose design solutions are often in the form of classes (in the object oriented paradigm) and describe how the classes relate to and communicate with each other and objects to solve a problem. The original architectural design patterns are somewhat different from software engineering patterns with the latter being more concerned with implementation than design. Just as the goal of the architectural patterns is to help architects build structures that possess a certain quality for their inhabitants, the goal of WBI patterns is to assist educators in designing web-based courses that are instructionally effective for students. Web-based instructional (WBI) design patterns are more closely related to architectural design patterns because the focus is more on the user’s experience with the final product. Patterns can be a powerful resource tool for designers within these domains, but our
working hypothesis is that novice designers need additional support in the process of selecting and applying patterns to their design problems.

This paper presents our approach for scaffolding the pattern user’s design tasks. In Section 2, we take a closer look at design patterns and current research results. Section 3 discusses design environments that have been proposed to support design pattern usage. In Section 4, we present our methodology for providing support for the application of patterns in web-course design and the resulting design environment. Section 5 concludes with a brief overview of our research objectives and future research directions.

2. Design Patterns

A design pattern captures a solution to a problem and presents it in such a way that the solution can be adapted and used repeatedly. Patterns go beyond simply presenting a solution; they also tell the user why the solution is needed and the context in which the solution can be applied. This information is presented in a format usually organized into several sections including the pattern name, which describes the design problem and provides a way to communicate about the pattern, the problem, which describes the design issues the pattern addresses, the context, which explains when to apply the pattern, the solution, which tells the user how to solve the problem, and the forces, which describe the trade-offs of applying the solution. Patterns usually exist within a language with other patterns addressing design problems in that same domain. A pattern language is a collection of patterns that are connected, thus allowing the designer to see how all the patterns within the language work together.

Our research is concerned with design patterns for WBI design. The need for design support has become a major issue in the design of web courses. The poor design of the instructional materials in web courses is one of the key problems with learning from the web (Bork & Britton, 1999; Kessler et al., 1999). Design patterns provide a mechanism for capturing pedagogical strategies and good design practices in a way that can assist educators in designing instructionally sound web courses. WBI design patterns vary in content from dealing with navigation design issues to addressing problems with student learning activities (Frizell, 2001; Rossi, 1996; Anthony, 1995). As in other areas of pattern usage, the goal is to support less experienced designers. Figure 1 gives an abbreviated example of a design pattern that has been proposed for web-course design (Frizell, 2001). This pattern addresses the isolation problem some web-based students have, and the solution describes to the designer a method for alleviating the problem.

There have been some preliminary studies on the effectiveness of pattern usage during the design process (Prechelt, 1997; Schmidt, 1995; Beck, 1987). Although this evidence has been in the realm of software engineering, preliminary results from these studies do show that patterns may prove beneficial to the design process. The benefits of design patterns may be greatly harnessed by coupling the patterns within an environment that supports the designer in working with the patterns in the language. We believe this to be especially true in a domain such as web-based instruction where the course designer may not have any experience in interaction and instructional design, and also in domains where the pattern language has grown to include a large number of patterns.
Name: Learning Community

Problem:
Some students have a need to feel connected with other students enrolled in the course. How to facilitate a sense of community for on-line students?

Context:
Web-based courses where students are feeling isolated.

Forces:
Students are not all on-line at the same time.
Some students prefer anonymity.
The difficulty of the medium.

Solution:
Provide an environment that encourages students to get to know other students in the course and to communicate with each other. This can be facilitated by having students post information about themselves. You can make the first assignment called ‘Introduce Yourself’. It can be in the form of a web page and contain information such as the student’s name, email address, interests, and a picture. This information can encourage interaction and dialogue among the students.

Web discussion tools such as bulletin boards can also be added to the course to encourage students to discuss topics. Students can go to the bulletin board to post problems and share ideas. You can also post questions on the bulletin board and require students to respond. This type of student interaction creates a sense of community for students.

Including Group Projects as a part of the instructional activities provides another mechanism to encourage a connection among students.

Rationale:
Creates a learning environment that encourages participation and interaction among the students. A course design that provides for a high level of interaction may alleviate some of the issues of learners who feel isolated and non-connected during on-line courses. In distance education courses, an attrition rate of 50% is common. By making students feel like they are part of a community, they may be more likely to participate and complete the course.

Related Patterns: Group Projects

Figure 1: WBI Design Pattern

3. Pattern Support Environments

Within the software engineering community, there has been some research on providing computer support for working with design patterns. Budinsky (1996) presents a design tool to support the implementation of design patterns in object-oriented software. Their tool supports browsing the patterns on-line and automatically generates the code for the pattern’s implementation based on information collected from the software designer. The objective was to automate the implementation of design patterns for the software developer. However, with this work they found that the problem that may exist in pattern application is not in the coding or development; it is in the designer understanding his problem and deciding which pattern(s) helps solve it best (Chambers et al., 2000).

Web-course design environments such as Shih (2000) and Thomson (2000) recognize the need for design support for pattern usage, but these environments mostly provide support for the navigational structure of web-based courses. Patterns are used to model optimal paths through the course and a design tool guides the designer in developing courses based on these paths.
Design environments such as the ones described above are heavily implementation oriented; a support environment for pattern usage in web-course design must also provide support for pattern selection.

4. Supporting the application of patterns in web-course design

Our research with design patterns is two-fold. We are working on a pattern language for web-based instruction to support designers in the creation of web courses and on a design environment to support our language. We focus the remainder of this paper on our methodology for providing this support and the resulting design environment.

Our goal is to provide support for three main activities, finding and selecting the appropriate patterns, and the application of the selected patterns into the course's design.

- **Finding Patterns**: We utilize a hypertext rendition of our pattern language to support browsing and quickly navigating through the patterns in the language. Patterns are grouped into categories based on the type of problems they address with cross-referencing between related patterns. This allows quick access to the patterns.

- **Selecting Patterns**: To support course designers in selecting the appropriate pattern(s) to solve their design problems, we provide support for pattern selection in two ways. We provide a menu-based approach, which allows the designer to search for patterns based on their course goal or problem. We also use a decision support system to guide the designer through the process of designing a course using a standard instructional design process combined with the patterns that address problems within each phase.

- **Applying Patterns**: After the course designer chooses the patterns he wants to use in his course's design, a design specification for the web-course is developed based on these selected patterns. The course design specification acts as a bridge from design to implementation. It gives the instructor an idea of how the course is structured based on his particular design decisions.

A designer that is experienced with working with the pattern language may not only know which patterns to select and how to apply them, but also follows an effective design process that includes the use of patterns as a subtask. It is important that the novice designer learns to not only work with the pattern language, but also gains a better understanding of design in general and design with patterns specifically. The process of finding, selecting, and applying patterns should be scaffolded for the novice designer. One of the characteristics of scaffolding is that support can be faded away over time giving the learner the control to apply their new knowledge and skills (Vygotsky, 1978).

We are developing a design tool named PatternEdge to explore the combination of a pattern language coupled with a method that scaffolds pattern usage for the designer. PatternEdge employs a dynamic web-based interface implemented with PHP and uses a relational database for storing patterns. A rule-based system supports the designer in the selection of patterns taking into consideration the characteristics of the learners and the goals and objectives of the course designer.

The overall approach is depicted in Figure 2. The patterns within the language are annotated for how and when they are best used. The inference engine can then use this information during the pattern selection process. When interacting with the system, the designer is able to browse through the patterns and select and apply them on their own as they would if the patterns were presented
without design support. Users also have the option of being able to seek design advice for working with the patterns. The system will collect information about the course to be designed such as learner characteristics and the instructor’s goals and objectives. Based on the information known about the course and interaction with the instructor, the tool suggests design solutions (i.e. patterns) to the instructor. The solution given could be a pattern to solve a particular design issue or a collection or subset of design patterns from the language to cover all aspects of a course’s design. After the selection of patterns, the tool generates a design specification for the web-based course based on these patterns. We believe this design specification could be integrated into an authoring tool to support the instructor in developing the course based on the design decisions.

Figure 2: Design Environment

5. Conclusion and Future Work

An objective of our research is to develop an environment that fosters educators in designing instructionally sound web-based courses through the development of a WBI pattern language and a method to support the effective use of this language. We believe end-users can benefit from having a design environment that scaffolds design pattern usage for them. Instead of merely focusing on implementation issues, this environment should provide support for finding and selecting the appropriate patterns. With PatternEdge, we provide this support. Future work includes evaluations with users to assess the effectiveness of the design environment in supporting pattern usage.

Abstract: Since the inception of the World Wide Web, faculty members have been developing online course materials. However, there is little careful analysis of how students use these Webs. In particular, do more successful and less successful students use course webs and associated materials differently? Are usage patterns similar to those of printed resources, or do students explore materials differently on the Web? To answer questions like these, educators and researchers need tools that allow them to closely examine student use of Web materials. Building upon user tracking tools that gather information on student usage, including the time each reader arrives at and spends on each page, the use of multiple windows, and the links followed from page to page, we implemented Clio's Assistants a customizable suite of tools that permit exploration of student Web usage patterns both graphically and textually. The graphical tools include simple bar Charts, customizable directed graphs, and "replays" of student sessions. Textual tools include simple statistical summaries, human-readable log files, database queries, and an advanced pattern matching language. Through these tools, one can identify and explore patterns of Web usage.

1 Introduction

Although a number of tools are used to create educational computing resources, the World Wide Web (Berners-Lee et al. 1994) is perhaps the most popular mechanism for creating computerized educational resources. The Web provides many advantages, including easy design of documents, "universal" access (most Web pages can be accessed from anywhere on the Internet), and the ability to incorporate local and remote documents in a course Web.

Students use course Webs in a variety of ways. For example, some students explore course webs using only one window while others open multiple windows (e.g., one to hold the current problem being studied, another to hold reference materials, and a third to hold current news). Similarly, some students will visit each link on a page while others will be very careful in their selection of links. Are there patterns that successful students seem more likely to use? Do students' usage patterns evolve over time? And, perhaps most importantly, can less successful students benefit from using the patterns of more successful patterns?

Scholars cannot answer any of these questions until there are ways to identify and explore these usage patterns. The goal of Project Clio is to provide tools that allow analysts to identify and experiment with usage patterns. Clio works in three phrases: gathering (Clio's Watchers), synthesis (Clio's Accountants), and analysis (Clio's Assistants). Clio's Watchers are a collection of tools that gather information while a student is browsing the Web. By using the Web Raveler architecture (Kensler and Rebelsky 2000), Clio's Watchers are able to gather information on student usage whether students are on a local or remote site. Because the data gathered by Clio's Watchers are repetitious and make some information (such as time on page) implicit, Clio's Accountants convert the raw data into more useful data that are then stored in a relational database. Finally, Clio's Assistants provide customizable ways to explore those data. The key aspects of Clio's Watchers are that they gather data for a group of individuals (e.g., all members of a course) and that the gather data for all pages those individuals visit, whether they are local or remote.

Clio's Assistants provide the focus of this paper. In Section 2, we describe the primary assistants. In Section 3, we describe a typical interaction with Clio's Assistants. In Section 4, we compare Clio and Clio's Assistants to other hypertext analysis tools. In Section 5, we revisit the need for Clio and Clio's Assistants. Finally, in Section 6, we consider future directions for Clio.

Clio's Assistants
A Tool Suite for Exploring Student Web Usage

2 Clio's Assistants: The Suite of Tools

The Clio's Assistants Tool Suite is a collection of tools, both graphical and textual, that allows analysts to explore the ways in which students use the Web. At the core of this exploration is the notion of classification. Although Clio's Assistants permit analysts to explore usage of individual pages (e.g., How long did the average student spend looking at exercise 3?), most assistants allow analysts to consider groups of pages (e.g., When confronted with an exercise, what kind of page did student X most likely visit before entering an answer? Or From what pages were students more likely to leave the local course Web?). The classification of pages is relatively straightforward: For each class of pages, the analyst enters (1) one or more patterns (e.g., "all pages whose URL begins with http://www.cs.grinnell.edu/~rebelsky/Examples/"), (2) a classification (e.g., "Examples") and (3) a shorthand for the classification (e.g., "E"). Classifications are stored permanently in the system. Links may be classified in two ways: by the internal link type (the REL attribute) or by pairs of patterns. Because links depend closely on the particular pages used (e.g., while a link from sect3.5.html to sect2.4.html in the same directory is probably a "prerequisite information" link, not all links between sections are prerequisite links), internal link types are preferred.

Once analysts have classified pages, they may explore the usage logs with both graphical and textual tools. These tools range from simple summaries (textual and bar charts) to complex representations of the data (e.g., as a directed graph or animation over time). Direct access to the "nearly raw" data is also available. In the following paragraphs, we describe the tools in more detail.

Bar Chart: Simple Graphical Summaries Often the best way to begin exploration of data is with a simple overview of the most "popular" parts of a site. Bar charts concisely represent a large amount of data in a simple and quick way. The Bar Chart tool permits analysts to quickly explore a number of comparative relations. For example, bar charts can be generated for number of visits versus URLs (for a group of students) to get a feel for which pages students visit most often, or time spent versus classification to explore how students are dividing their time. We are currently exploring ways to let analysts explore the data within each bar of the chart. For example, upon finding that students spend a lot of time on example pages, an analyst might then ask to see a bar chart of the most popular URLs for example pages.

Summary Statistics: Simple Textual Summaries While the Bar Chart tool provides a general overview of popularity, the overview is limited to one type of thing (URLs, Classification, etc.). The Summary Statistics tool generates a variety of statistical information about the browsing session of a particular user or multiple users. While we are currently exploring the most appropriate information to provide, it currently provides the mean and median time spent on pages, most visited URL, most visited Web domain, most visited classification, and similar data.

Slideshow: Graphical Replays When exploring the patterns of a single student, it is sometimes most useful to watch exactly what the student did: what pages did she visit and in which order, with which on the screen simultaneously. While it would be best to be able to watch over the students shoulder, the Slideshow tool provides a reasonable substitute in that it "replays" the original Web pages visited by the students chronologically, with multiple simultaneous pages shown in different frames. This display is supplemented with additional information, such as time spent on each page and the referring page. This tool is particularly useful when the content of the page, and not just the classification, is of interest.

Directed Graph: Complex Graphical Summaries The tools described so far provide only basic information about usage. How can an analyst find more complex patterns? The Directed Graph tool provides users with a more sophisticated graphical means of examining a browsing history. A directed graph consists of nodes (dots) and directed edges (arrows) that are used to illustrate Web pages and link between those pages, respectively. Different characteristics of the nodes and edges can be set to correspond to different aspects of the pages and links. For example, different colors might represent different classifications and different node sizes might represent different amounts of time spent on a page. Similarly, the color of a link might represent its classification. Alternately, the color of a node might represent the sequential time at which it was visited (making it easier to consider patterns involving multiple windows; similarly colored nodes are likely onscreen at the same time).

Each of a node's four characteristics can be associated with one of eight attributes of the corresponding Web page. The node characteristics are color, size, horizontal position, and textual label. Page attributes include URL, classification, site, title, sequence number (in terms of pages visited in current window), arrival time, maximum time on page, and total time on page. At present, each link has only one customizable characteristic, its color. The color may represent link type, sequence number, or number of times the link was followed.
Each node of a directed graph represents a distinct (window, URL) pair. The directed graph is displayed in one of two frames, with the second frame being reserved for node information. When a node is clicked on, information such as number of page visits, timestamps and URL all become visible in the second frame. Also located in this frame are controls for zooming in and out on the entire graph.

The directed graph may prove beneficial to those who can most easily see patterns with the aid of visuals. Because many nodes and edges can all be examined quickly, patterns of usage become apparent to the user. Combining the graphical means of pattern exploration with the highly customizable attributes of the graph, the directed graph can be an excellent tool for pattern analysis.

**Pattern Matching: Complex Exploration of Log Files** Once an analyst has identified a pattern through one of the previous tools (e.g., they may see one student who follows many links, but often backtracks, as if they followed the wrong link) or through speculation (e.g., one might postulate that good students always check prerequisite links; the best students quickly realize that they know the prerequisite material and return to the page), analysts may then wish to explore when and how often that pattern occurs within the browsing history of a single student or the class. The Pattern Matching tool is particularly useful for searching through the logs of all students being tracked and letting the analyst see how many and who are following a certain pattern. For example, consider the following sequence of events:

1. The student went to a 'Search Engine' page.
2. The student went to a 'Search Results' page for less than ten seconds.
3. The student went back to a 'Search Engine' page.

This pattern would most likely indicate a failed search. Because the Pattern Matching tool relies on classifications, failed searches can be found at Yahoo and Lycos, not just Google. The Pattern Matching tool has a small language embedded in it that shortens queries to just a few characters. For example, the pattern above would be written in this language as `SE/SR{<10}/SE`. SE here stands for Search Engine, SR for Search Results, the '/' indicates, "and then," and the brackets indicate a time interval. The Pattern Matching language provides a number of other special patterns, including an "or", an "at the same time as" and even a way to classify pages on the fly. The results are returned as time intervals for a particular user, and links are provided to the directed graph, the log file, and the slideshow.

We consider the time-on-page pattern particularly useful as it helps one distinguish between apparently similar by actually dissimilar navigation strategies. Consider the pattern "Problem, Reference Page, Example". A student who follows that pattern may be one who wants to read the reference completely and then view some examples. It could also be one who is simply using the reference page as a quick way to get to an example because there is no link to an example from the problem. How can you tell the difference? If the student spends a lot of time on the reference page, the student is probably reading the page. If the student spends only a short amount of time on the reference page, the student is probably using the page as a quick way to get to an example.

**“Nearly Raw Data”: Log Files and Database Queries** As we worked to develop these tools, we interviewed a number of faculty members and instructional multimedia technology specialists to see what features they might want. A few noted, in effect, “While I’d probably use your tools for my initial exploration, I really want access to the raw data for my final analysis". Viewing the log files is another means of analyzing the information available in our database. The log file can be downloaded in CSV format or viewed online. CSV files can be viewed in many spreadsheet programs. Online viewing allows for the creation of links and the ability to link between the various Clio Analysis tools. One can sort and select the data chronologically or by any other information displayed.

Because the data are stored in a relational database, we also expect to provide a mechanism for direct database queries using SQL. However, that remains a future goal.

### 3 Extended Example

Let us consider a sample session in which one uses Clio’s Assistants to explore students Web use. Professor Peabody is interested in studying where and how his students find their information for a particular assignment. Peabody asked his students to turn on Clio while searching for answers on the Web. (For issues of privacy, he first discusses the uses of Clio with the students and obtains their permission.) Several days later, the professor has his students turn in their solutions to their assignments as well as stop using Clio. He then accesses the analysis tools with his favorite Web browser and begins using Clio’s Assistants.
Peabody begins by viewing the log files of his students. The information presented to him appears as a series of rows with information about each page the students visited. Having received permission to correlate homework scores with student identifiers, Peabody notes that Student 5 did a wonderful job on his homework and he now views the log file just for Student 5. Because Peabody believes that the log file contains the most information, he begins there. A quick scan of the beginning of the file shows that Student 5 spent a lot of time on the reference pages. However, as Peabody jumps to the end of the file, he sees that most of the entries there are for examples. Two questions quickly arise: Did Student 5’s exploration change over time and what kinds of pages did Student 5 use most, the early reference pages or the later example pages?

The second question is perhaps the best place to start. Professor Peabody selects the Bar Chart tool and asks for a comparison of number of visits vs. classification. Both examples and reference pages appear quite frequently. However, Professor Peabody is stunned to see that the most-visited classification was “Course Front Door” and the second most-visited classification was “Search Engine”. Two new questions arise: Why did Student 5 revisit the course front door again and again? Was he lost in cyberspace? Perhaps more importantly, why did Student 5 use search engines so frequently?

Peabody asks for summary statistics for Student 5 on the front door. He sees that the average time spent on the page is less than twenty seconds and that the most common referring page is "no referrer". What does that mean? It probably means that Student 5 makes it a habit to jump back to the start of the course web when moving on to new information. Perhaps Student 5 likes to ground his exploration from a comfortable place. A quick check of the directed graph shows a pattern that looks very much like what he postulated: lots of long straight trails that begin with the front door. Is this answer conclusive? No, the best way to find out more is to speak with the student, as in the work described in (Jones and Berger 1996).

Now Professor Peabody wonders what the student was searching for outside of the course web. He sets up a pattern to request all sequences of the form “Search Engine, Results Page, Any Other Page”. He expects that by scanning the pages received, he will obtain additional information on what kinds of things Student 5 was looking for. He notices two things. First, that many of the search results that Student 5 selected are within his course web. That suggests that the student is just using the search engine to find pages with the course web. Is that an indication that the links on his pages aren’t good, or that Student 5 prefers to search rather than to use links? Another reason to talk to the student. The other thing Professor Peabody notices is that many of the other results are all within a certain domain. It’s probably worth exploring whether he should make direct links to those pages.

Before going on to other things, Peabody decides to revisit the question of whether students need a search engine to find pages within his course web. He looks through all students for the pattern “Search Engine, Results Page, Page in My Course Web”. He finds that Student 5 is the only student who uses that pattern. Now it’s time to consider whether or not that’s a technique he should suggest to other students.

4 Conclusions

Most discussions of the World Wide Web in education focus on the direct benefits the Web provides for students: Easier access to material, ability to explore material at the speed and in the manner that best suits the student, availability of a greater variety of materials. Project Clio provides a very different benefit: Clio’s goal is to help faculty understand, through data analysis, the pattern and personality of students’ usage of the World Wide Web. For Clio to fully assist in the analysis of data, Clio must allow the analyst to explore the various patterns of learning that individuals undergo. Such learning patterns include: active and passive approaches to discovery (Dufresne and Turcotte 1997) and different searching methods (Jones and Berger 1996). By providing a suite of tools that take learning styles into account, we are expanding the boundaries of this underdeveloped area of research. We hope that once scholars are able to identify successful patterns, those patterns can be incorporated into Web sites and taught to less successful students.

The greatest strengths of the Clio’s Assistants tool suite are: (1) the diversity of tools available; (2) the interconnectedness of the tools, which permits the results of one tool to be used in another; (3) the ability to record information for a number of students on arbitrary sites, (4) the customizability of the tools, particularly the directed graph tool; (5) the support for information not commonly available, such as time on page and the use of multiple windows; and (6) the richness of the pattern matching language.
5 Future Goals

The first goal of the Clio team is to try the tools in a real classroom situation. We are currently negotiating with some faculty to classify their pages and require their students to use Clio. However, such trials require a more robust version of Web Raveler (currently under development) and a careful consideration of the impact on students. We expect to gather our first data in Fall 2002 and analyze it in the subsequent semester.

Many of the Clio Assistant tools need to be expanded. For example, the Log File tool should be expanded to allow an analyst to select portions of the log file so as to "dig in" to particular parts or patterns. For example, one might first select just the entries for a particular day, then just a particular classification. At the more advanced end of the spectrum, we are hoping to animate the directed graphs so that one can see the graph expand over time, providing an alternative to the slideshow and giving another node characteristic (that is, when the node appears on the screen). We also expect that an animated directed graph will help reveal important aspects of sessions in which students return to certain pages repeatedly.

We are also considering other appropriate tools. As suggested earlier, we are considering ways to give direct SQL access to the data and looking for interesting queries that one might want to make using SQL. We are also considering whether it might be appropriate to present logs in some form of 3-dimensional "world", in which there would be additional opportunities to represent attributes of pages and links (Kmiec et al. 2002). Since the current tools rely on the intuition of those using the tools to find patterns, we are also looking at ways to use data-mining techniques to automatically find patterns (Pinchback et al. 2002).

Finally, we need to consider some subtle issues in more depth. For example, there is a question as to whether a page can receive multiple classifications. For the purpose of the pattern-matching tool, it makes sense to permit a page to be classified in many ways. However, for the directed graph tool, it seems that only one classification can be used at a time (if an example is red and a page about topic X is green, what color should an example about topic X be?). We expect that these kinds of issues will be revealed and clarified as the Clio Assistants are used by a variety of analysts.

Acknowledgements

We are particularly grateful to the Grinnell College Mentored Advanced Project (MAP) fund for the funding for the research described within this paper. The work benefited from the modern computing equipment in the department of Mathematics and Computer Science, equipment funded by Grinnell College and The Arthur Vining Davis foundation. Our work builds upon the prior work of others in the Grinnell Laboratory for Interactive Multimedia Experimentation and Research (Glimmer), particularly Andrew Kensler, who built the first version of Web Raveler, the Summer 2000 Web Raveler team (Peter Broadwell, Elizabeth Hulse, Chris Kern, and Erin Nichols), who developed a more robust and modular implementation, the Summer 1998 Clio Team (Raphen Becker and Kevin McLaughlin), who built the first prototype of the Clio tools, and the Summer 2000 Clio Team (Rachel Heck, Kumail Nanjiani, Eleanor Raulerson, and Izabela Staicut), who built the Web Raveler plugins to gather and synthesize data. We are also grateful to the other Summer 2001 research students who provided guidance in the Web Raveler system and who gave us suggestions for our own work: the Annotations team (Khong Lovan, Elias Vafiadis, and Joshua Vickery) and the Links team (Angela Kmiec and Melissa Piper Pinchback). Finally, we appreciate the time of the Grinnell College faculty and staff who took the time to discuss the analysis of student data with us.
Abstract: Despite major differences in course delivery, the critical components of effective online mathematics teacher education may not be different from the critical components of effective face-to-face mathematics teacher education. Research indicates that components of effective mathematics teacher education include (a) aesthetic experiences with mathematics, (b) confronting personal beliefs about mathematics, (c) engaging in practical inquiry, and (d) discussing pedagogical implications in the context of mathematics education literature. This paper describes the case of an online mathematics education course for in-service elementary teachers, and discusses issues of design and effect of online experiences.

Introduction

McGowen & Davis (2001a) suggest that we need an “antidote” to teachers’ conceptions of mathematics as learning procedures and getting right answers. Findings show that such conceptions are consistently associated with observed practice of teachers (McGowen & Davis 2001a, 2001b; Stipek et al 2001) and that teachers who hold such conceptions of mathematics have lower teacher self-confidence and enjoy mathematics less than teachers who hold inquiry-oriented conceptions (Stipek et al 2001). Attempts to change teachers’ mathematics conceptions and teaching practice through teacher education and professional development programs focusing on inquiry-oriented mathematics instruction “are minimally effective, in part because teachers filter what they learn through their existing beliefs” (Stipek et al 2001, 214). Teachers assimilate new ideas without substantially altering existing beliefs that drive their practice (Cohen & Ball 1990). In terms of affecting classroom practice, the new ideas are either ignored or they are interpreted and distorted through the lens of existing beliefs. In this paper we posit that instruction needs to provide critical experiences that lead teachers to pedagogical thinking and practice that enable them to move towards an inquiry-oriented conception of mathematics.

Critical Experiences

Critical experiences may be defined as those experiences that cause teachers to reflect on their knowledge, experience and beliefs and help them see mathematics and mathematics teaching in a new light. When moments of epiphany occur, mathematics education artifacts – such as past experiences, curriculum documents, classroom situations, ideas from professional development workshops, from education articles, and so forth – can be seen as inkblots in which the image (or idea) appears to shift and teachers see something new, something that was not apparent to them before. As one teacher in one of our studies commented, “I feel like [this experience] has cleaned my spectacles and I am reading the [curriculum] document with new vision”. Similar findings are reported in a study by McGowen & Davis (2001b) where one teacher noted that the experiences provided in a course of study “opened my eyes to a new outlook on mathematics” (444).
In our research we have concentrated on aesthetic aspects of critical experiences. Contrary to the usual alignment of "critical" with "rigorously intellectual", participants in our study demonstrate that critical engagement occurs within an aesthetic context (Gadanidis, Hoogland & Hill 2002). This was true for teachers with diverse mathematical backgrounds and attitudes that ranged between positive and negative. It is interesting to note that although aesthetic qualities of critical experiences for mathematics teachers are not explicitly identified in related studies, aesthetic qualities are in some cases implied. For example, McGowen & Davis (2001b) make use of phrases such as "we focused on a [...] beautiful experience in establishing connections" (439) and "the atmosphere [...] was electric" (440) to describe aspects critical experiences for mathematics teachers.

Research on mathematics teacher development (Cohen & Ball 1990; Gadanidis, Hoogland & Hill 2002; McGowen & Davis 2001a, 2001b; Stipek et al 2001) indicates that the following are integral components of critical experiences:

- Teachers confront their beliefs about mathematics.
- Teachers have aesthetic experiences with mathematics.
- Teachers engage in practical inquiry.
- Teachers consider pedagogical implications in the context of relevant mathematics education literature.

Design and Effect of an Online Course

The discussion of the design and effect of a full-credit additional qualification online mathematics education course for elementary in-service teachers [referred to hereafter as Online Course] is organized around the four components of critical experiences outlined above. It should be noted that although the design of the course incorporated these components, the components were explicitly identified after the course was designed and taught. The original design of the Online Course was based on successful learning experiences for teachers that emerged from face-to-face professional development sessions. In the discussion below we highlight the design similarities between the Online Course and the face-to-face professional development sessions that inspired the design of the course. We hope to illustrate that the components of critical experiences for mathematics do not depend upon a particular environment – be that face-to-face or online. Rather, that critical experiences depend upon the quality and nature of instruction as identified above.

Prior to developing the Online Course the instructor was a mathematics consultant for a large school district, dealing mostly with elementary mathematics program design and teacher development. This experience reinforced research findings that many elementary teachers view mathematics as procedures to be learned for getting right answers (McGowen & Davis 2001a, 2001b; Stipek et al 2001). One of the goals of district-wide professional development was to help teachers become aware of these beliefs and to examine them critically. Bringing teachers face-to-face with their unexamined beliefs about mathematics involved more than simply telling or showing teachers what mathematics is really like or how it may be different from their personal beliefs. Teachers were provided with opportunities to personally experience aesthetically-rich mathematical contexts, which were different than the teachers’ historical experiences with mathematics or the experiences they may have been providing for their own students. Likewise, teachers in the Online Course were provided with similarly aesthetic mathematics experiences. Such experiences created a reflective context for examining personal in both the face-to-face and the online environments.

Experiencing aesthetically-rich mathematics does not have to involve complex mathematics, especially for elementary teachers. Some of the mathematics experiences in the Online Course involved teachers in mentally solving arithmetic problems such as 16 x 24 and 156 + 78 + 9 (see Activities 1 & 2 in Figure 1). These activities were chosen based on their positive effect in previous face-to-face workshops conducted for elementary teachers and parents. In such workshops, typically half the people in each group were asked to solve a problem like 16 x 24 or 156 + 78 + 9 in their heads and half the people to use pencil and paper. After a few minutes, people shared and explained the methods they used in their groups. Then the discussion was opened up and people shared and explained other methods. It quickly became apparent that the people who used paper and pencil methods had little to say. One reason for this was that most people used the same procedure. Another reason was that although they were able to describe the procedure they followed, they often were not able to explain why. Some people reverted to statements like “this is how it works – it’s just a rule”. On the other hand, people who solved the problem in their heads shared a variety of methods and they understood what they were doing and why they were doing it. They displayed pride in their individual approaches to problem solving. There was an excitement about mathematical thinking in the room, with people eager to share their personal methods.
and quick to express surprise and praise for unique methods that others shared. A palpable energy was created in
this exchange.

We suggest that the experience of mentally solving 16 x 24 or 156 + 78 + 9 is aesthetically rich in that
the mental processes involved do not demand rule-based procedures. How people solve 16 x 24 depends greatly
on how they personally interpret the problem. For example, some people may multiply 16 and 25 and then
subtract the extra 16. Others may deconstruct the problem as 10 x24 + 6 x 24. Many other solutions processes
are possible – even ones that use algebraic structures like (20 - 4)(20 + 4). Given such problems, people are
eager to share their solutions, they express interest and sometimes surprise in the solutions of others, and are
motivated to try to come up with different solution processes. Open-ended inquiry, interest, surprise and
motivation are characteristics of an aesthetic approach.

Teachers in the Online Course noticed that their mental solution processes were “different than when I
did it with paper and pencil because I solved my problem by starting with the bigger numbers first (left to right,
not right to left!)”. Such experiences appear to have helped teachers move towards questioning traditional views
of mathematics and developing a deeper understanding of what constitutes mathematical activity and
mathematical understanding in the context of addition and multiplication. “To me, the implications are that doing
arithmetic mentally requires real understanding. The traditional way (on paper, doing the "ones" first) is more of
a procedure to be memorized that requires little understanding”.

In face-to-face professional development, practical inquiry was facilitated through a double-session
structure. Between sessions tried out new ideas in their classrooms and shared their experiences and reflections
in the second session. Teachers were encouraged to bring to the second session samples of student work. Many
of the insights that teachers gained and shared arose from observations of students doing mathematics and
thinking mathematically in the context of the new ideas that teachers tried in their classrooms. The Online
Course involved teachers in practical inquiry in that teachers were asked to explore the thinking of others,
including the thinking of their own students, in mentally solving problems like 16 x 24 and 156 + 78 + 9 (see
Activity 3 in Figure 1). They shared and reflected on these observations in online discussions. Many of the
teachers tried the problems with their students and discovered that they too used a variety of methods, and
usually not standard paper and pencil procedures. This helped teachers realize that their mathematical thinking as
adults was similar to that of their students and different from the standard paper and pencil procedures. Teachers
were impressed by the creativity of student answers and questioned their reliance on paper and pencil
procedures.

Asking teachers in the Online Course to mentally solve problems like 16 x 24 and 156 + 78 + 9 and to
share their solution processes also offered opportunity for practical inquiry into the nature of mathematics and
doing mathematics. This set the context for discussions of related pedagogy. However, one would expect that
practical inquiry would also involve experimenting with teaching practice, which was not a requirement of the
Online Course. Unlike the face-to-face professional development described above, the Online Course did not
explicitly ask teachers to experiment with new teaching ideas in their own classrooms. This is something that
will be reconsidered when redrafting the Online Course.

In face-to-face professional development sessions, ideas from mathematics education literature were
shared and discussed. The Online Course gave teachers the opportunity to read such literature. Two articles
about children inventing personal algorithms for arithmetic operations (Burns, 1994; Kamii et al, 1993) provided
a context for teacher reflections on their thinking when mentally solving problems like 16 x 24 and 156 + 78 + 9
and for considering pedagogical implications. “To guide your thinking” questions (see Figure 1) directed teacher
attention to pedagogical issues. In contrast to the face-to-face professional development sessions where ideas
verbalized may be forgotten, an advantage of the Online Course was the ‘permanent' record of discussions.
Many teachers revisited past discussions and created scrapbooks of ‘good ideas' by copying sections of online
transcripts in word processing documents. As was the case in the study by McGowen & Davis (2001b), teachers
made important connections between their experiences and ideas in the articles they read.

I do agree with Kamii and Burns' points of view. I think that by having the student discover a successful
method they will be more likely to internalize and understand the concept. In coming up with their own
methods they are doing the thinking the way their mind works. We can see [in our discussion] that
everyone processes things differently.
Discussion

Research indicates that many teachers are unaware that an alternative to a procedural view of mathematics exists (McGowen & Davis 2001b). The interplay between the mathematics experiences, journal readings, online reflections, and discussions created for many of the teachers in the Online Course a critical experience that helped them ‘see’ mathematics and mathematics teaching in a new light. As one teacher commented,

After seeing how different people calculate, I better understand this last overall expectation in [the curriculum document]. Hmph! It is not until I do something myself, do I more fully understand the language and what the curriculum is really driving at. Thus students need to explore different ways of doing calculations, talk about it, communicate their ideas in a variety of ways. I feel like [this experience] has cleaned my spectacles and I am reading the document with new vision.

A critical aspect of the Online Course was that teachers confronted their personal beliefs about mathematics and mathematics teaching in the context of practical inquiry with aesthetically-rich mathematics problems. In solving such problems, in observing students solve them, and in sharing, comparing and discussing solutions teachers realized that mathematics problems might be solved in many different ways. Another critical aspect was the reading and discussing journal articles that placed such experiences in the broader context of mathematics pedagogy. Online discussions allowed the personal kind of sharing that created community. This is not to suggest that such critical experiences created changes in teachers’ perceptions of mathematics and mathematics teaching that were comprehensive or permanent or that significantly affected their classroom practice. How teachers teach is also greatly affected by accepted teaching practices in the wider school community (Buzeika, 1999; Ensor, 1998) and by conflicting priorities (Skott, 1999). However, such critical experiences, whether they are in online or face-to-face teacher education or professional development settings, may be important starting points for change in classroom practice.

Conclusion

There are important characteristics of online learning such as text-based communication and asynchronous discussion that distinguish it from face-to-face learning. However, the cases of the Online Course and the face-to-face professional development discussed above indicate that the components of critical experiences transcend such differences. These components include (a) aesthetic experiences with mathematics, (b) confronting personal beliefs about mathematics, (c) engaging in practical inquiry, and (d) discussing pedagogical implications in the context of mathematics education literature. We believe that in the design of online courses for mathematics teachers, the primary focus of teacher educators should be not on the technological differences but, rather, on the quality and the components of the critical experiences.
A. How do you think mathematically?

Let's take a close look at how your mind performs arithmetic operations. Try the following activities:

Activity #1:
- Multiply 16 and 24 in your head.
- Record the process you followed.
- Now multiply 16 and 24 on paper using the procedure you were taught in school.

Activity #2:
- Add 156, 78 and 9 in your head.
- Record the process you followed.
- Now add 156, 78 and 9 on paper using the procedure you were taught in school.

Activity #3:
- Ask someone else (a student, a teacher, a friend) to solve the following and then tell you the processes they used:
  - Multiply 16 and 24 in their head.
  - Add 156, 78 and 9 in their head.

To guide your thinking:

How are the processes you use to multiply or add in your head similar to or different from the paper and pencil procedures you were taught in school for multiplying or adding?

B. Jean Piaget

Jean Piaget, who spent a lot of time researching the mathematical thinking of young children, said that there are three types of knowledge (Kamii et al 1993):

1. **Physical knowledge:** This is the knowledge of our physical environment. For example, colours of objects, or the fact that an apple falls when you release it from your hand.

2. **Social knowledge:** These are, in part, the rules and conventions that we make up to make our social life run smoothly. For example, we all agree that a red traffic light means stop. Social knowledge is to some degree arbitrary. For example, we could all agree to stop on a green light and go on a red light.

3. **Logico-mathematical knowledge:** This is the knowledge of relationships. This knowledge allows us to see patterns and make connections in situations. For example, we can see two circles as representing a pair of glasses, the number eight, or a snowman. Or, when considering the following question, we can see different relationships that lead to different answers: Which one of the numbers 3, 4, 5, and 7 does not belong?

To guide your thinking:

Think about the procedures you learned in school for multiplying or adding numbers on paper. Which type of knowledge do they represent? Why?

Think about the processes you used earlier for multiplying or adding numbers in your head. Which type of knowledge do they represent? Why?

Think about the mathematics you learned in school. How would you classify it in terms of Piaget's knowledge categories? Can you identify some examples in each category?

Asynchronous Video-Based Instruction with Variable Speed Playback: Is Faster Better?

Joel D. Galbraith, Steven G. Spencer
Center for Instructional Design
Brigham Young University, Utah (USA)
joel_galbraith@byu.edu

Abstract: In the summer of 2000, Variable Speed Playback functionality was added to an asynchronous video-based accounting course at Brigham Young University. This paper reports the results of student surveys on the use and value of VSP in the course. Student feedback was exceptionally positive on the value of being able to dynamically control the speed of their lectures-on-demand up to 2.5 times normal speed with no pitch distortion. On average, student time viewing lectures was reduced by over half, with no reduction in average quiz and exam scores.

Introduction
In recent months there has been a proliferation in higher education institutions of online lecture-based steaming media. New digital and streaming video technologies steadily facilitate the potential for increased user control over audio and video media (Galbraith 2000). Variable Speed Playback (VSP) represents a significant increase in user control over this linear medium. VSP, also known as Time-Scale Modification (TSM), or time compression, involves adjusting the duration of temporal content. From a student's perspective, VSP can be used to "speed through boring or redundant material and slow down for interesting, challenging or new portions of audio and video presentations."

In the Fall of 2001, tests began at Brigham Young University (BYU) on the 2xAV VSP plugin from Enounce Inc. (www.enounce.com). The 2xAV plugin provided a degree of control over their video-based accounting lectures that students had requested over previous semesters. When surveys were distributed to assess if student needs were adequately met with this tool, developers were caught off guard by both the overwhelmingly positive feedback received, and the average rate of acceleration employed. This feedback forced developers to research whether or not student claims of increased learning and sustained attentiveness at higher speeds were substantiated by previous research.

The research (Harrigan 2000, 1995) appears to bear out the students consensus that VSP abilities helped them stay more focused, learn more, and increased their exam scores—all at a significant time savings. One student responded, "In order to grasp everything [at higher speeds] it is necessary for me to pay closer attention. This fosters greater understanding of the course material. Since I started using the plugin, my grades have gotten better."

The Study
VSP abilities were made available to 2,400 students enrolled in a video-based, entry-level accounting course at BYU. Learners could view lectures at up to 2.5x the normal speed. Significantly, both speeding up and slowing down the audio is accomplished without pitch distortion (i.e., the sound does not sound like chipmunks when accelerated). A 6-item survey was made available to the students via the web-based course management system (Blackboard). Approximately 40% of course enrollees responded to the survey over the last two semesters, totaling 924 respondents (n=924).
