PM-ENA History and Goals

PME came into existence at the Third International Congress on Mathematical Education (ICME-3) in Karlsrühe, Germany in 1976. It is affiliated with the International Commission for Mathematical Instruction. PME-NA is the North American Chapter of the International Group of Psychology of Mathematics Education. The first PME-NA conference was held in Evanston, Illinois in 1979.

The major goals of the International Group and the North American Chapter are:

- To promote international contacts and the exchange of scientific information in the psychology of
- mathematics education;
- To promote and stimulate interdisciplinary research in the aforesaid area, with the cooperation of
- psychologists, mathematicians, and mathematics teachers;
- To further a deeper and better understanding of the psychological aspects of teaching and learning mathematics and the implications thereof.

PM-ENA Membership

Membership is open to people involved in active research consistent with PME-NA's aims or professionally interested in the results of such research. Membership is open on an annual basis and depends on payment of dues for the current year. Membership fees for PME-NA (but not PME International) are included in the conference fee each year. If you are unable to attend the conference but want to join or renew your membership, go to the PME-NA website. For information about membership in PME, go to igpme.org and click on "Membership" at the left of the screen.

Preface

These Proceedings are a written record of the research presented at the 35th Annual Meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education (PME-NA 2013) held in Chicago, Illinois, November 14-17, 2013.

The theme of the conference is Broadening Perspectives on Mathematics Thinking and Learning. Dr. Nicolas Balacheff focuses on a model, cK¢, to think about learners´ mathematical conceptions. Dr. Na'ilah Suad Nasir focuses on race and culture in mathematics education. Dr. Tobin White and Dr. Melissa Gresalfi address technology in mathematics education in a panel format.

The Proceedings include papers from 1 plenary talk, 2 panel presentations, 68 research reports, 121 brief research reports, 208 posters, and 14 working groups. The plenary and working group papers are the first and last chapters, respectively. Papers from the research reports, brief research reports, and posters are organized into chapters by topics. Each paper is indexed by authors and keywords. Underlined author indicates presenting author.

We would like to thank Janet Liao Kornas for her dedication to the technical details of putting together a high quality document. We are pleased to present these Proceedings as an important resource for the mathematics education community.

cK¢, A MODEL TO REASON ON LEARNERS' CONCEPTIONS

Nicolas Balacheff
CNRS - Laboratoire d'Informatique de Grenoble
Nicolas.balacheff@imag.fr

Understanding learners' understanding is a key requirement for an efficient design of teaching situations and learning environments, be they digital or not. This keynote outlines the modeling framework cK¢ (conception, knowing, concept) created with the objective to respond to this requirement, with the additional ambition to build a bridge between research in mathematics education and research in educational technology. After an introduction of the rationale of cK¢, some illustrations are presented. Then follow comments on cK¢ and learning. The conclusion evokes key research issues raised by the use of this modeling framework.

Keywords: cK¢, Conception, Misconception, Knowing, Milieu, Didactical Situations, Conceptual Fields, Learner Modeling, Design Experiment, Technology Enhanced Learning

A Short Story

The model I will introduce has a long history. Its construction started at the end of the 80s with the project of bridging artificial intelligence and didactics of mathematics, and the objective of enhancing the design of computer-based learning environments. The design of these environments had a ternary structure including a model of the learner, a model of the content to be learned and an instructional model. These models are nowadays either effectively implemented, or only involved in the design phase. For the last two, research has constantly been very active with some promising progress. On the contrary, modeling the learner proved to be a real challenge, and actually it is still the case despite expectations raised by recent research on educational data mining and learning analytics.

The theoretical framework within which I was working, the Theory of Didactical Situations (TDS), is based on ideas that some may consider as precursors of "learning games" now celebrated by researchers in educational technology:

> "*Modeling a teaching situation consists of producing a game specific to the target knowledge among different subsystems: the educational system, the student system, the milieu, etc*."
> (Brousseau 1986/1997 p.47).

Within this approach, the teacher is "*a player faced with a system, itself built up from a pair of systems: the student and, let us say for the moment, a 'milieu' that lacks any didactical intentions with regards to the student*" (ibid. p.40). A systemic approach to learner modeling makes possible expressing learning as adaptation and adaptation as construction. However, while research went quite far in modeling didactical situations, the progress on modeling the learner "*subsystem*" was rather limited. Indeed, there was a lot of research within different frameworks, with different concepts and a variety of terms, reporting observations of learners' behaviors. But the distance between the content of these reports and models that we could use to inform the design of learning environments, was quite significant.

As a researcher in mathematics educations, I had another motivation. I started my research on the learning of mathematical proof in the 70s, with an exploration of the structure of proofs produced by students, using graphs to represent them. This approach was intrinsically limited, so it was not too difficult to understand the critiques of Guy Brousseau and Gérard Vergnaud. The former drew my attention to the role of the situation; the latter pointed to the cognitive

complexity of producing proofs. Then, I engaged in a completely different direction which resulted at the end of 80s in a first picture of what could be the genesis of mathematical proof. While this picture could help designing didactical situations, it didn't shed light on the underlying mental processes. In other words, it was a didactical study, not a psychological study. Still, there was a weak point: it left open a gap between proving and knowing. To close this gap I had to find a way to model the learner's ways of knowing. The Vergnaud model of concept and conceptual field offered a possible solution:

> "[…] *from a developmental point of view, a concept is altogether: a set of situations, a set of operational invariants (contained in schemes), and a set of linguistic and symbolic representations.*" (Quoted from Vergnaud 2009 p.94, but this characterization goes back to the early 80's)

Vergnaud introduced the notation: C=(S, I, $\mathcal{S}$) in which the components refer respectively to each of the three sets mentioned above. He emphasized that these components cannot be separated; they have to be considered all at the same time when studying learners' development. This characterization has direct connections with the TDS description of the relation between a learner and a milieu based on different forms of knowledge (Brousseau ibid. p.61):

[1] The models for action governing decisions.
[2] The formulation of the descriptions and models.
[3] The forms of knowledge which allow the explicit "control" of the subject's interactions in relation to the validity of her statements.

Apart from the set of situations (S) which is implicitly shared, common elements are related to action (I) and formulation ($\mathcal{S}$). Then, one element is missing which corresponds to the terms "control" used in the TDS description. I mentioned this lack when discussing the Vergnaud concept of theorem-in-action. A theorem, and the same applies to a theorem-in-action, is both a tool and a statement: "if A then B" is a tool to obtain B if A is valid, it is also a statement which has a truth value. This duality of "*the operational form and the predicative form of knowledge*", as Vergnaud expresses it, facilitated keeping implicit the control dimension in the characterization he proposed. However, after Polya and a long tradition of research on metacognition, Schoenfeld (1985 pp. 97-143) has shown the crucial role of control in problem-solving. The suggestion I made consists in introducing explicitly this dimension of control in Vergnaud model. This is the origin of the quadruplet I describe below.

Before entering the main content of this keynote, I would like to address an issue which led me use the term "conception" and not the term "knowledge" as it is classical in educational technology and mathematics education as well. Most of our research is based implicitly or not on the hypothesis that learners act as rational subjects. But, one often is faced to rational thinking co-existing with knowledge which looks contradictory (from the observer's point of view). Bourdieu (1990) proposed a solution to this paradox: "*The calendar thus creates ex nihilo a whole host of relations [...] between reference-points at different levels, which never being brought face to face in practice, are practically compatible even if they are logically contradictory*" (ibid. p. 83). The key elements are time on one hand, and on the other hand the diversity of situations. Time organizes the subjects' decisions sequentially in such a way that even contradictory, they are equally operational because appearing at different periods of their history: contradictory decisions can ignore each other. The diversity of the situations introduces

an element of a different type. It is a possible explanation insofar as one recognizes that each decision is not of a general nature but that it is related to a specific sphere of practice (we would say, nowadays, that it is situated) within which it is acknowledged as efficient. Within a sphere of practice learners are coherent and successful; they are non-contradictory.

Contradictions (and failures) appear when learners are faced with situations foreign to their sphere of practice but in which they have nevertheless to produce a response (e.g. a question from an interviewer). They mobilize what they have available which worked elsewhere, but more often than not this ends in systematically making errors. The classical position in the 80s was to consider these errors as symptoms of misconceptions. This term used to come with expressions like "naive theory", "private concepts", "beliefs" or even "mathematics of the child". Such views missed the fact that "*a child may not be 'seeing' the same set of events as a teacher, researcher or expert. […] many times a child's response is labeled erroneous too quickly and […] if one were to imagine how the child was making sense of the situation, then one would find the errors to be reasoned and supportable* " (Confrey 1990 p.29). Agreeing with this position, I renounced using the term "misconception". Still, recognizing that learners may have different models-in-action to mobilize for (what we consider as) the same piece of knowledge, I needed a term, but one different from "knowledge" because of the issue raised by the observation of possible contradictions in learners behaviors. A possible term was "conception" largely used in science education to denote theory-in-action. Most often than not conception functioned as a tool in discourses but it was not taken as an object of study as such (Artigue 1991, p.266), although there was an acknowledged need (e.g. Vinner 1983, 1987) for a better grounded definition of conceptions, and for tools allowing analyzing their differences and commonalties. In the following section, I propose a definition of "conception", and then describe a model revisiting the Vergnaud's triplet.

Behavior, Conception and Knowing

The only indicators one has to get an insight into learners' understanding are their behaviors and products which are consequences of the conceptions they have engaged. Such evaluations are possible and their results are significant only in the case where one is able to establish a valid relationship between the observed behaviors and the invoked conception. This relation has been relatively "hidden" as such for a long while as a result of the fight against behaviorism, but it has always been present in educational research at least at the methodological level. Indeed, the key issue is that *the meaning of a piece of knowledge cannot be reduced to behaviors, whereas meaning cannot be characterized, diagnosed or taught without linking it to behaviors*.

Being a tangible manifestation of the relationships between a person and her environment, a "behavior" depends on the characteristics of this person as well as on the characteristics of her environment. A now well documented example is that of an instrument which at the same time facilitates action if the user holds the required competence, and on the other hand limits this action because of its own constraints (Rabardel 1995, Resnick & Collins 1994, p.7).

The words "person" and "environment", which I am using here, refer to complex realities whose aspects are not all relevant for our investigations. One may want to ignore the clothes the person wears and the shape of the room in which he or she stands (although we have always to be prepared to consider seriously features initially downplayed). What is of interest is the person from the point of view of his or her relationship to a piece of knowledge. For this reason I will refer from now on to the learner as a reduction, if I dare saying so, of the person to her cognitive dimension. In the same way, I do not consider the environment in all its complexity, but only those of its features that are relevant with respect to a given piece of knowledge. Actually, this

corresponds to the TDS concept of *milieu*, which is a kind of projection of the environment onto its epistemic dimension: the milieu is the learner's antagonist system in the learning process (Brousseau, 1997 p.57)

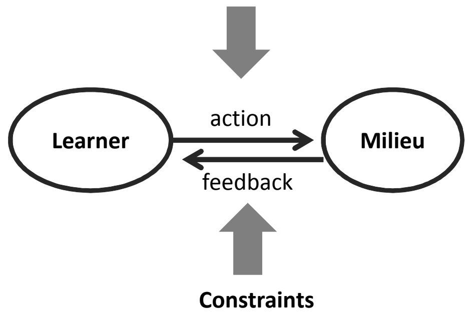

Figure 1. learner/milieu system

This situatedness nature of a conception suggests not considering it as a property which can be ascribed only to the learner but as a property of the interacting system formed by the learner and his or her antagonist milieu, to which I will refer as the "learner/milieu system". What is requested for this property to be valid is that the system satisfies the necessary conditions for its viability. I mean that the system has the capacity to recover equilibrium after a perturbation which otherwise would cause its collapse, or that it can transform itself or reorganize itself. This is another formulation of Vergnaud's postulate that problems (perturbed system) are the sources and the criteria of knowing (Vergnaud 1981 p.220). It is important to realize that nothing is said about the process leading to the recovery of the equilibrium under the said constraints. They are proscriptive (Stewart, 1994 pp. 25-26), which means that they express necessary conditions to ensure the system viability, but not prescriptive, which means that they do not say in what way an equilibrium must be recovered.
Hence, a definition of conception:
A conception is the state of dynamical equilibrium of an action/feedback loop between a learner and a milieu under proscriptive constraints of viability.
The study and characterization of a conception will be based on observable behaviors of the system (action, feedback) and outcomes of its functioning. It requires evidence of the assessment of the equilibrium, which depends on the possibility to elicit the learner's control of the interaction and of the milieu's reification of failures and success by adequate feedback.

Geometry provides many good examples: constructing a diagram on a sheet of paper with a pencil is permissive to empirical adjustments, while dynamic geometry software allowing messing up a diagram by dragging points can reify the failure of conforming to geometrical properties (Healy et al. 1994)—but still, "students may modify the figure 'to make it look right' rather than debug the construction process" (Jones1999 p.254).

The situated nature of a conception means that for different situations considered conceptually the same or for problems claimed isomorphic, one may associate different conceptions with the same learner. There is a large documentation of this phenomenon in the literature, for example under the theme of transfer, or from research in ethnomathematics. Anyhow, in the researcher's referential system, these different states of the observed systems [learner in a situation] should be labeled in the same way. For this reason, I define a *learner's knowing* as the set of conceptions which can be activated by different situations the observer considers conceptually the same—a qualification that indeed one will have to clarify. I realize that using "knowing" as a noun is rare, but it helps keeping distance with the word "knowledge" which has in education a strong authoritative connotation.

Having this definition of conception and of its relation to knowing, in the next section, I propose a model inspired by Vergnaud's formalization which I develop in the next section. Some examples will illustrate the model and facilitate clarifying the intention of my research program.

Outlines of a Model

What is a model could be discussed at length within the PME multidisciplinary research community. I take here a pragmatic position, looking for something likely to facilitate our collaboration with research in educational technology, but also as a means to make more efficient our own research. The objective is to contribute to a better understanding of learners' understanding and to have eventually a practical value for teachers and designers.

It should be emphasized that the terms "conception", "knowing", "concept" and several others appearing in the description of the model are abstract terms, whose meaning is that of their functions and relations within the model. Indeed, we must then discuss how far the proposed formalization makes sense when confronted with "reality", and if it is an adequate tool for our research. The examples I will present and some additional comments will hopefully partly respond to this preoccupation.

I call "conception" a quadruplet (P, R, L, Σ) in which:

- P is a set of problems.
- R is a set of operators.
- L is a representation system.
- Σ is a control structure.

The first three elements are almost directly borrowed from the Vergnaud triplet. The vocabulary is different to avoid confusion with the vocabulary of psychology. In particular, operators correspond to actions one can observe in the functioning of the learner/milieu system; they are not schemes in psychological terms. The representation system is formed of all the semiotic tools which allow representing problems, supporting interaction and representing operators if formulations were required. The characterization of the set of problems P is more complex than expected. Two opposite solutions have been proposed: (i) to include all problems for which the conception provides efficient tools (Vergnaud 1991 p.145), but for basic concepts this option is too general to be effective; (ii) to consider a finite set of problems from which other problems will derive (Brousseau 1997 p.30), but this option opens the question of establishing that such a generative set of problems exists for any conception. A solution familiar to most researchers consists of deriving the description of P from both the observation of students in situations and from the analysis of historical and contemporary practices of mathematics. Actually, what one does when working on specific conceptions is to open a window on P by making explicit a few good representatives of its potential elements. These representatives work as kind of prototypical problems; this is a pragmatic implementation of Brousseau's proposal.

The forth element of the quadruplet, the control structure, includes behaviors such as making choices, assessing feedback, making decisions, judging the advancement of a problem solving process. These metacognitive behaviors are more often than not silent and invisible, hence rarely accessible to observation. It is why, to overcome this difficulty, one uses specific experimental settings, for example inviting learners to work in pairs, with the expectation that this will be enough to elicit these behaviors.

It is worth noticing that the quadruplet is not more related to the learner than to the milieu with which he or she interacts: the representation system allows the formulation and the use of the operators by the active sender (the learner) as well as the reactive receiver (the milieu); the control structure allows expressing the learner's means to assess an action, as well as the criteria of the milieu for selecting a feedback. It is in this sense that the quadruplet characterizing a conception is congruent to the conceptual definition of a conception as a property of the learner/milieu system.

This formalization not only allows characterizing conceptions and hence providing a framework to discuss their diagnosis, it has also the potential of helping to establish links among conceptions more precisely.

Shaping Relations Between Conceptions

Arithmetic, From Fingers to Keystrokes

Addition has been widely studied, so there is enough resources to document what learners' conceptions could be like. This first example shows how eliciting the four dimensions of the quadruplet provide a synthetic and precise picture of the conceptions chosen for the purpose of the illustration (there are several others).

C1: Verbal counting IIIII & IIII
P -- *prototype*: "You have 5 pebbles, I give you 4 more, how many have you now?" (Objects are present or represented in an analogical way, both numbers are small).
R – match fingers and objects, match fingers and number names, pointing to objects,
L -- body language (finger counting, pointing), number naming, verbal counting
Σ – not counting twice an object, counting all the objects, order of the number names
C 2: Counting on 16 & 4
P -- *prototype*: "You have 16 pebbles, I give you 4 more, how many do have you now?" (The numbers are given, but the collections are not present, one of the numbers must be small enough)
R -- choose the greater number, count on to determine the result.
L -- body language (finger counting), number naming, verbal counting.
Σ -- order of the number names , match of fingers to number names
C3: written addition 16+23
P -- adding two integers
R -- algorithm of column addition
L -- decimal representation of numbers
Σ -- check the implementation of the algorithm, check the layout of number addition
C4: Pocket calculator [1][6][+][2][3][=]
P -- adding two integers, the result is bound by the size of the screen
R – keystroke to represent a number, to process number addition
L -- body language (keystrokes), decimal representation of numbers on the screen
Σ – keystrokes verification, order of magnitude.

Table 1: Four Examples of Conceptions of Addition

First, the quadruplet puts to the fore the domain of validity of these conceptions, none of which can be claimed wrong but might be badly adapted outside their spheres of practice. For example, C1 will not be reliable in the domain of C3 and really difficult to implement in that of C2. For very large numbers, C4 will not work unless extended with additional strategies to deal with the limits imposed by the technology (e.g. screen display). Beyond the remark that the two first concern quantities and the two others concern numbers, one can compare the conceptions on each dimension of the quadruplet and analyze in an accurate way their commonalities and differences. One can also express relations often considered among conceptions; for this it is necessary to introduce a function allowing passing from one system of representation to another. Let us take the case of generality:

[*C is more general than C' if there exists a function of representation*
f: $L' \to L$ so that $\forall p \in P'$, $f(p) \in P$]

So, one can show that C3 is more general than C2 and C4, but for different reasons although in both cases the size of the numbers is at stake. Indeed, we obtain in this way something that intuitively and informally would have been seen without such a sophisticated formulation. Isn't there here a flavor of pedantry? I hope not. It is just good to check that the formalism can express

familiar facts but, indeed, it must go far beyond that and be capable of revealing less obvious relations.

The Challenge of Translation

The exercise of formalizing generality puts on the fore the importance of *translation*, a process we engage anytime we analyze learners activities. To emphasize the importance of the manipulation of representation systems, I take another example from the history of mathematics: ancient Egyptian arithmetic. The mathematical papyruses have been translated in the contemporary mathematical language, including the processes used to solve some problems. Figure 2 displays the sequence of steps to compute “10 times 1/5” (Couchoud 1993 pp.21-22). I will not here explain how the scribes obtained the result, 2, out of this sequence and how they moved from one line to the other. Looking closer to these processes suggests that the translation of  by 1/5 is misleading. What is denoted by the Egyptian sign is “five parts of the whole”, hence an integer but integers which could not be added as integers are. These representations were not computed, instead scribes used tables to establish the correspondence between two numbers to be multiplied and the result. The control structures associated to this ancient conception of “fractions” and the modern one are completely different. Moreover, if one wants to consider passing back from the modern conception to the Egyptian one, that is expressing any fraction as a sum of unitary fractions, he or she will enter a new mathematical chapter. Several algorithms are available to compute an Egyptian decomposition for any fraction. For example, for 4055/4093 one will get the shortest and unique additive decomposition: [1/2 + 1/3 + 1/7 + 1/69 + 1/30650 + 1/10098761225]. Unfortunately, Egyptians could not write the last term. Analyzing these conceptions along the dimensions of the quadruplet in a systematic way makes easier figuring out what separates them.

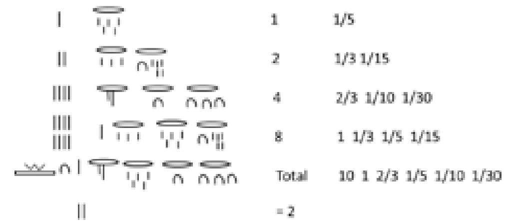

Figure 2: 10 times 1/5

Discussing learners’ conceptions in the context of the mathematical curriculum is more difficult because operators and representation systems are often very similar. In this case, the control structure may be the discriminating element. As a matter of fact, this touches the foundation of conceptions because of the legitimacy controls provide by validating them.

Let us take a case in school algebra. In his research questioning the “production of meaning for Algebra”, Romulo Lins (2001 p.47) observes the activity of students to whom he proposed the following task:

To calculate how many oranges will fill into each box, we divide the total number of oranges by the number of boxes, i.e.:

orange per box = $\dfrac{\textit{number of oranges}}{\textit{number of boxes}}$

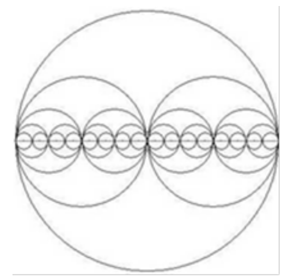
If I tell you the total number of oranges, and the number of oranges in each box, how would you calculate the number of boxes used?

Justifying the task, Lins writes: “*The reason for presenting the ‘algebraic’ formula was to ascertain whether the pupils would constitute it into an object, dealing with it in the process of solving the problem; neither of them made any reference whatsoever to this formula*” (ibid.) In a very pragmatic way students manipulated oranges and boxes: “*They always used a number of something*” (ibid.). They dealt with quantities and not numbers. The control on their reasoning

comes from the concrete reference the context makes possible. Actually, if algebra had been called up, literals would have been used to speak about actions on objects of a referent world made of boxes and oranges. This phenomenon is familiar, as Boero (2001 p.108) reports following a research he carried out in a different context: "*some students seem to transform the problem situation by thinking about the number of sheet and the weight of the envelope as physical variables*" whereas others "*put into a numerical equation the problem situation and transform the equation*".

Invited to write a postscript to the book "*Perspective on School Algebra*" (Sutherland et al. 2001), where I analyzed the reports of Lins, Boero and several others, I introduced the expression "*symbolic arithmetic*" to distinguish from algebra those conceptions in which symbols are manipulated and rules used with the supervision of a control structure grounded in the referent context.

In the following case, the role of the control structure clearly makes a difference between two conceptions which on the other hand seem to share the representation systems and operators.



Questioning Controls to Understand Representations

This case, which I have often presented, is as an excellent prototypical example of the complexity of identifying conceptions. The excerpt is borrowed from the work of Bettina Pedemonte (2002) on argumentation, cognitive continuity and proof. She chosen the problem described below and proposed it to pairs of students—the idea of having pairs was driven by the expectation to get spontaneous comments about actions, choices and decisions taken during the problem solving process.

"*Construct a circle with AB as a diameter. Split AB in two equal parts, AC and CB. Then construct the two circles of diameter AC and CB… and so on.*

How does the perimeter vary at each stage?

How does the area vary?"

Using the formulas they know well both students, Vincent and Ludovic, express the perimeter and the area for the first steps in the series of drawings. They agree to conjecture that the perimeter will be constant and that the area will decrease to zero. But soon Vincent notices that "*the area is always divided by 2…so, at the limit? The limit is a line, the segment from which we started…*" This observation raises a conflict about the value of the perimeter which, in the opinion of Vincent, should be the length of the segment:

41. *Vincent*: It falls in the segment… the circles are so small.
42. *Ludovic*: Hmm… but it is always $2\pi r$.
43. *Vincent*: Yes, but when the area tends to 0 it will be almost equal…
44. *Ludovic*: No, I don't think so.
45. *Vincent*: If the area tends to 0, then the perimeter also… I don't know…
46. *Ludovic*: I will finish writing the proof.

Although Vincent and Ludovic collaborate well and seem to share the mathematics involved, the types of control they have on their problem-solving activity differ. Ludovic is working in the algebraic setting (Douady 1985) where control is based on a constant checking of the correctness of the symbolic manipulations conforming to the syntax of elementary algebra. Vincent is working in a symbolic-arithmetic setting where the control comes from a constant confrontation between what the formula "tells" and what is displayed by the drawings. So, both understand the initial situation in the "same" way, both manipulate the symbolic representations (i.e., the

formulas of the perimeter and of the area) following the right syntax, but their controls are radically different. The symbolic representation supports the cooperation of the problem-solvers but it does not impose a shared understanding: as a *boundary object* it is flexible enough to adapt to the different meanings but robust enough to work as a tool for both students. To identify the differences beyond the apparent commonalities of representations one has to question learners' decisions and choices, which means identifying the control grounding their activity.

Conception, Knowing and Concept

Understanding learners' conceptions requires their interpretation from the perspective of our own conception which we claim related to the same content of reference; one may say: the same concept. This can be expressed within the terms of the model, putting on the fore the role of translation which is more often than not implicit in our research practice. Let's take the case of "falsity" which is defined in the model in the following way (with a natural coding of the respective quadruplets):

> [*C is false from the point of view of C' if there exists a function of representation* $f: L \to L'$, *and there exists* [$p \in P$, $r \in R$, $\sigma \in \Sigma$, $\sigma' \in \Sigma'$] *so that* $\sigma(r(p))$=*true and* $\sigma'(f(r(p))$=*false*]

In other words, there exists a problem from the sphere of practice of C which has an accepted solution but which is assessed "false" from the point of view of C'.

"Generality" and "falsity" are not properties of conceptions but relations between two conceptions whose validity depends on the translation from one system of representation to the other. This is a general situation often hidden by the fact that we tend to read the production and the processes learners carry out directly in mathematical terms. Not being aware of this may make understanding learners difficult, as illustrated by Linns remarks on students' inability to escape the concrete reference of a situation he sees himself as mathematical. More generally, we have a tendency, often implicit, to consider ourselves as privileged knowers entitled to judge and evaluate other people's knowings. Such ambition requires at least that we can claim that the conception one assesses and the conception one holds are—so to say—ontologically compatible; they are concerned by the same object. This is difficult in mathematics where the only tangible things one manipulates are representations, and representations of representations. This can be solved within the model, taking Vergnaud's postulate as a grounding principle: problems are sources and criteria of knowings (1981 p.220):

> *Let C and C' be two conceptions and* C_a *be a conception more general than C and C'. This means, with a natural coding of the respective quadruplets, that there exist functions of representation* $f: L \to L_a$ *and* $f': L' \to L_a$ *which relate C, C' and* C_a. *Then:*
>
> [*C and C' have the same object with respect to* C_a *if for all p from P there exists p' from P' such that* $f(p)=f'(p')$, *and reciprocally*]

The fact that two conceptions have the same object does not mean that they have another type of relationship (one being false with respect to the other, or more general, or partial, or else), it may be the case that problems of P' (resp. P) cannot be expressed with L (resp. L'); and if they are, the translated problems may not be part of the sphere of practice of the other conception (e.g. the case of the conceptions of addition, Table 1). Eventually, conceptions have the same object if their defining problems (or their spheres of practice) can be matched from the point of view of a more general conception which in our case is the conception of the researcher. Research on mathematics learning must start with an introspection of researchers' own conception of the content at stake; questioning this conception is the first methodological tool to assess the validity

of what can be said about learners' conception. This corresponds to the a priori analysis in the methodology associated to the TDS.

"To have the same object with respect to a conception C_a" sets an equivalence relation among conceptions. Let's now claim the existence of a conception Cμ more general than any other conception to which it can be compared; this seems to be an abstract declaration, but pragmatically it corresponds to a piece of a mathematical theory.

I call "concept" the set of all conceptions having the same object with respect to Cμ.
This definition is aligned with the idea that a mathematical concept is not reduced to the text of its formal definition, but is the product of its history and of the set of practices in different communities. Indeed, there is no agent holding the concept and no way to ensure that we can enumerate a complete list of these conceptions. So, a last definition will allow reducing the distance between this abstract definition and the needs we have to have a practical model:

> *I call "knowing" any subset of a concept which can be ascribed to a cognitive subject or a community.*

In practical terms, this definition of conception and knowing provides a framework which preserves learners' epistemic integrity despite contradictions and variability across situations. In a way which might seem more usual, I could summarize the ideas presented here in the following way: a *conception* is the instantiation of a *knowing* by a situation (it characterizes the subject/milieu system in a situation), or a *conception* is the instantiation of a *concept* by a pair (subject/situation).

The name cK¢ comes from the names of the three pillars of the model: *conception*, *knowing*, *concept*. I keep the word "knowledge" to name a conception which is identified and formalized by an institution (which is a body of an educational system in our case).

Problems, Conceptions and Learning

Indeed, most problems are not solved by activating just one conception. So we need to be able to express the relation between a problem and conceptions which contribute to its solution, but without having to give details about this solution because of the cost of a too thin granularity. For this reason, I propose the more general idea of a *set of conceptions solving a problem*:

> *Let p be a problem, and {C1,…, Cn} a set of conceptions.*
> *{C1,…, Cn} solves p iff there exists a sequence of operators* $(r_{i1}, \ldots, r_{im})$ *whose terms are taken in one of the* R_i *so that the sequence* $(p_1=r_{i1}(p), \ldots, p_{im}=r_{im}(p_{im-1}))$ *verifies that there exists* σ *from* Σ_{im} *so that* $\sigma(p_{im})$*=solved.*

From this general characterization, one can derive more precise properties, for example expressing that a conception is specific to a problem (any set of conceptions solving it contains this conception), or that conceptions are equivalent from a problem solving perspective (one can replace the other without changing its property vis-à-vis the problem). Exploring this possibility evidences that problems and conceptions are of a dual nature: on the one hand conceptions need problems as constituents of their characterization, and on the other hand problems get their meaning from the conceptions contributing to their solutions. This duality suggests a natural connection between conceptions by the mediation of problems: this is exactly the idea of Vergnaud's conceptual field.

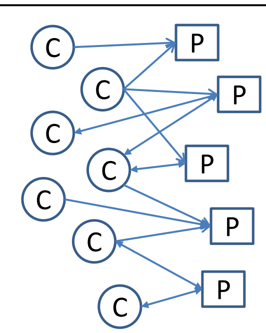


Figure 3: Duality of problems and conceptions

Learning is a process whose outcome is an evolution of conceptions being reinforced, questioned or transformed. The motor of this process is problems, which are (in our terms) destabilizations of the learner/milieu system. This destabilization can be obtained by modifications of constraints on the interaction between the learner and the milieu or modifications of the characteristics of the milieu (cf. Figure 1)—indeed, the learner is a "subsystem" on which no direct action is possible. The most difficult task is to find problems questioning the control structure and/or the representation system because the former is mostly implicit in the activity of learners and the role of the latter is invisible to their eyes once they are familiar with it. To overcome these difficulties is the *raison d'être* of the TDS situations of formulation and validation, which are based on a social organization of the class and a play on the characteristics of the milieu. I will not elaborate on this relation between cK¢ and the TDS, a part from noticing briefly here that within a didactical *problématique*, learning can be modeled as a transition function on a bipartite graph of conceptions and problems. Problems are the means to activate and (i) diagnose a conception, (ii) destabilize a conception to obtain an evolution, (iii) reinforce a conception.

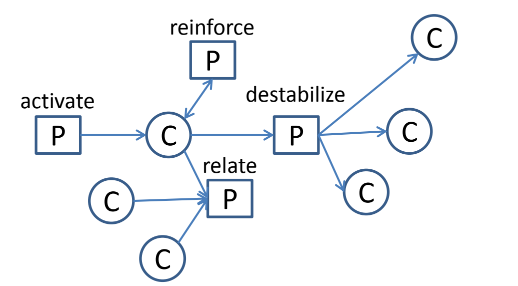

Figure 4: sketch of a bipartite graph conceptions/problems

Let C be the current diagnosed conception and C_t a targeted conception (the expected learning outcome). The most critical evolution is the one to be obtained when C is false with respect to C_t. To engage the learning process, it is necessary to find a problem for which a representation is possible within both C and C_t, and which could be a means to reveal a conflict: a solution is conceivable from the perspective of C, but is not accessible in a way that the milieu witnesses and the subject recognizes. It may appear that such a problem does not exist and that intermediary problems, and possibly intermediary conceptions, are necessary to "reach" C_t. Learning is often not a single step but a path in the graph. To identify and create the conditions to bring this path to reality within a learning situation, in particular within a classroom, is one of the core objectives of the TDS.

Let's take the classical and well documented case of the sum of the angles of a triangle. The most common initial conception is that the bigger the object the bigger its measurable characteristics (e.g. area, perimeter), hence the sum of the angles. The operators are those involved in the manipulation of geometrical instruments (rule, compass, protractor, etc.) and symbolic arithmetic, the control structure includes visual control of actions and checking of computations. To activate this conception, one can ask students to draw triangles, measure angles and add up the obtained results. The variety of the results in the class will not raise questions since triangles are different; students will be reinforced in the confidence that they have the capacity to achieve the task. But measuring angles is not sufficient to destabilize the conception and give room to the targeted conception which is rooted not in the manipulation of the geometrical "object" but of its property. A possible way out is of asking learners to repeat the task, all with the same triangle (e.g. reproduced on a worksheet); the problem of deciding of the results for *this* single triangle will emerge and challenge the operators of the initial conception. More is needed to question its core theorem-in-action, this will come from the orchestration of the confrontation of the outcomes of collective workshops on triangles with contrasting shapes (small, large, sharp, flat). The destabilization of the initial conception can be overcome only by

engaging in geometrical arguments of a theoretical nature. At this point, operators and controls are questioned, but the ambivalent nature of the triangle being both an object (of the spatio-graphic space) and a (geometrical) representation will (probably) remain unsolved.

Concluding Forewords

cK¢ proposes a framework for "learners modeling" taking up the challenge of providing a model of an epistemic relevance to bridge research in mathematics education and research on educational technology. It responds to a need for representations both understandable by researchers in mathematics education and computationally tractable. The formalism it dares should enhance the way one informs the design of technology enhanced learning environments, complementing descriptions generally available in natural language with no standardized narrative structure.

A European multidisciplinary assessment project (Baghera 2003) has been an occasion to check the efficiency of cK¢ in supporting a productive conversation between researchers in education and in computer-science. But probably more interesting for us is the powerfulness of this framework to think and develop our own research. Research in mathematics education develops jointly theories and experimentations, in this context models serve as mediators between theories of which they require an articulate and precise understanding, and experiments of which they frame the design and drive the collection of data. However, both theories and experiments raise difficult issues. On the side of theories, one has to deal with a complex discourse which rarely makes explicit all details and hence gives room to non-univocal interpretations. On the side of experiments, the practical implementation is always richer and more complex than what the design of models anticipates. Moreover, in the case of conceptions, one is confronted with issues (that Toulmin already noticed when proposing a model of argumentation): distinguishing operators from controls is not absolute (e.g. theorems can be activated as tools or predicates), controls are more often than not implicit. Such difficulties require further theoretical as well as methodological investigations.

Initially based on the Theory of Didactical Situation and the Theory of Conceptual Field, the cK¢ modeling framework is not restricted to them. For the purpose of its development and in order to enhance its efficiency it is necessary to integrate other theories to strengthen its components (e.g. representation, control system). But cK¢ holds other promises; it facilitates building a bridge between knowing and proving, constructing a link between control and proof, hence facilitating understanding the relation between argumentation and proof. But this is another topic which connects the research agendas I have had along my career, first on the teaching and learning of mathematical proof, then modeling learners' conceptions for the design of learning environments.

TECHNOLOGY IN MATHEMATICS EDUCATION: A DISCUSSION OF AFFORDANCES

Melissa Sommerfeld Gresalfi
Vanderbilt University
melissa.gresalfi@vanderbilt.edu

This paper details a framework for evaluating the potential of particular forms of technology for supporting student engagement with mathematics. I propose that, focusing on the strength of affordances to engage in particular ways allows us to begin to build an analytic frame that serves two purposes: (1) to begin to document learning as an interaction with larger bodies of data; and (2) to make and evaluate conjectures about the potential of different technologies for supporting high quality engagement with mathematics. I describe design iterations from previous work that leveraged this framework as an example of how this framework could be used and why it has proven to be valuable.

Keywords: Technology, Data Analysis and Statistics, Learning Theory, Design Experiments

Introduction

We seem to be in an upswing of technology adoption, with the general belief that more technology is better. We can see this in one-laptop-per child programs, charter schools that advocate the use of technology such as "New Tech High," the enthusiasm for "blended learning," and even the popular BYOT programs at schools, which encourage children to bring in any form of technology that they have at their disposal. I find this enthusiasm puzzling, to say the least. Technology, as a general term, refers to such a broad range of tools that it is difficult to understand why anyone would immediately believe (or doubt) that it would improve education. COULD technology become a resource to support student learning? Of course. Could it also thwart student learning? Absolutely. It's all in which forms of technology, how they're being used, by whom, and when. The questions we need to pose involve not whether technologies are useful, but which technologies, and under what circumstances.

In this paper I discuss a framework for considering the potential of particular forms of technology for supporting student learning, drawing on work that I have published that has focused specifically on particular forms of student engagement. I then share some of my own work on designing and studying immersive videogames, and leverage this framework as a means of making sense of the potential of these technologies. In so doing, my goal is not to take a position about whether technology is useful for supporting mathematical learning or not, but instead, to suggest a way of thinking about technology that would better allow us to evaluate whether, when, and why leveraging technology would make a difference for mathematics learning.

A Theory of Context

In 2008, Jim Greeno and I published a chapter that focused on considering "opportunities to learn" as a set of *affordances* for learning. Drawing on Gibson's (1979) theory of perceptual affordances as a framework, this paper described human activity as a co-constructed set of possible actions defined by: 1) the affordances of the environment for a particular action; 2) the intention of the agent to take up those affordances; and 3) the effectivities of the agent to actually

realize those affordances (c.f. Barab, Cherkes-Julkowski, Swenson, Garrett, Shaw, & Young, 1999; Gresalfi, Barnes, & Cross, 2012). *Affordances* refer to the set of actions that are made possible by a particular object; for example, a chair affords sitting, but a door does not. Of course, the extent to which an affordance can be acted on has to do with one's *effectivities*, an individual's ability to realize those affordances. To return to the earlier example, because of their quite different effectivities, a chair affords sitting for a human, but not for an alligator. And finally, the extent to which an affordance is realized depends on the dynamic *intention* that emerges among the elements of the system; just because one could sit on a chair does not mean that one does so, depending on the situation. Thus, understanding what happens at a particular moment requires unpacking what was afforded, and how those affordances were recognized and realized. It is important to note that something can only be afforded if it can be recognized and acted on; what makes an affordance actionable is inherently a dynamic relation between the environment and person (Greeno & Gresalfi, 2008). This focus on interaction acknowledges that a particular task might make something possible, but doesn't make it obligatory.

This framework helps to suggest a way of documenting "situated learning," that is, the assumption that what someone is able to do and, eventually, learn, is inextricably tied to the particular context and circumstances in which one is acting (Greeno & MMAP, 1998; Lave & Wenger, 1991). Situative and sociocultural theories of learning receive a lot of attention in educational research in general, and in mathematics education in particular. However, it is one thing to claim that learning is an interactional accomplishment; it is quite another thing to demonstrate how that is so. Much of the research in this area has relied on micro-level analyses of discourse and gesture, painstakingly demonstrating that what one person does cannot be separated from the other things that were done to/for/around that person at the same time (Engle & Conant, 2002; Esmonde & Langer-Osuna, 2013; Esmonde, Takeuchi, & Radakovic, 2011).

Despite their quality, these kinds of analyses are not scalable; they cannot be applied to large numbers of students with the goal of understanding whether and why a particular intervention worked as it did. Instead, for those large-scale questions, we often rely on assessments that target one particular moment in time and offer that moment (or a difference between two such moments) as evidence of learning. Condensing an entire learning activity to a single moment is problematic, but even more problematic is that these assessments are themselves part of an interaction (that also includes the learner), and thus understanding what someone demonstrated that they "know" cannot be reasonably accomplished without a careful analysis of what or how the assessment itself contributed to that moment of knowing. This kind of analysis is rarely, if ever, done, and thus we are left in a situation wherein we can offer detailed, textured analyses of learning as an interaction among a small number of students, but can offer no such analysis with larger numbers of students. What is missing, it seems, is a theory of context that could be leveraged in a scalable way such that larger studies of learning could also functionally offer analyses of learning as an interaction.

The Strength Of Affordances

In my own work, I have considered context as having affordances that make it more or less likely that someone will act in a particular way. In documenting what people do in relation to these affordances, we come to understand someone more nuanced about moments of knowing. In Gresalfi (2009), I proposed a framework for characterizing the nature of affordances that focused on the relative strength an affordance offered to enact a particular activity (see also Gresalfi, Barnes, & Cross, 2012). Specifically, an affordance was characterized as "strong" when it

required students to comply or when not complying would have been a social or rule violation. In contrast, a weaker affordances provides an opportunity for something to happen, but does not make it imperative that the affordance is realized. A videogame can offer a nice example of the contrast. In some videogames, the player is encouraged to collect particular objects as they play, which can be used for some purpose in later game play. In some contexts, the players are merely encouraged to be on the lookout for these objects—picking them up, or not, is voluntary. In that case, the affordance that is offered is relatively weak; picking up objects is possible, but not mandatory. In contrast, much stronger affordances could be offered if the game prevents a player from moving on if objects have not been collected. In this case, the affordance for collecting objects is very strong, because not doing so prohibits continued engagement with the game.

In this work, characterizing the strength of affordances, that is, attempting to make progress on a theory of *context,* allowed a different understand *individual* performance. As an explanation of why, consider a paper written by Ilana Horn in 2008 about "turnaround" students. Horn followed seven students at two schools, all of who had initial experiences of mathematical success despite having previous histories of lower mathematical achievement. She labeled this year their "turnaround" year, and then followed these seven students through the rest of their high school career. Four students were in a school that offered tracked mathematics classes, while the other three students were in a school that did not offer tracked mathematics classes. Horn (2008) offers great detail about the differences between these schools in terms of the *figured worlds* (Holland et al, 1998) that they offered to students; a very brief summary is that the tracked school offered a narrative of success being possible for some, but not all, while the de-tracked school offered a narrative that anyone could be successful if they put forth the effort. Horn documented that, in their "turnaround" year, all seven students were in classes that supported a shift in their identities to consider themselves to be good at math. However, in subsequent years, in the absence of this class structure, students in the tracked school reverted to their earlier mathematical performances and self-perceptions, ultimately enrolling in remedial math or dropping out of math altogether. In contrast, students in the de-tracked school all enrolled in college preparatory math, and completed, at a minimum, the courses they needed for college acceptance. Horn's (2008) goal was to document how structure can influence identities, and the particular importance of curricular structure and teacher beliefs in shaping the kinds of figured worlds that allow identities to develop and persist. However, equally interesting is the question of what was similar about students' "turnaround" experiences, and how that was related to what happened in later courses.

One could characterize this finding as illuminating the difference between students when they are offered strong opportunities to engage with mathematics through the activity of meaning making, in 9th grade, and then later only weak opportunities. Specifically, students in the tracked school were working with an extremely skilled teacher who was awarded the Presidential Award for Excellence in Mathematics and Science Teaching. She has been the focus of significant analyses for her skill at maintaining rigor while broadening participation and collaboration (Staples, 2007). In short, she was a very skilled teacher who created strong opportunities for students to experience success in her classroom. However, when moved to classrooms with teachers who arguably offered weaker opportunities to engage, these students, for whatever reason, failed to take up those opportunities. In contrast, the students who continued to be successful worked both in their 9th grade year *and* throughout high school with a department of math teachers who shared an approach to teaching that intentionally welcomed diverse forms of participation, leveraged heterogeneous grouping practices, and believed that all students could

succeed (c.f. Boaler & Staples, 2008; Staples, 2008). Like the students in the tracked school, students in the detracked school were offered strong affordances for students to engage deeply with mathematics and experience success. However, the students in the detracked school *continued* to be offered strong opportunities to engage in these meaningful ways. Suddenly these students are not "bad at math," but rather need stronger opportunities to engage in order to be successful. But crucially, if offered those opportunities, they *are* indeed successful. This recasting offers a clear way of conceptualizing performance as a shared accomplishment between person and environment, and helps us to recast failure and success as something that lies not just on the shoulders of teachers, or students, but both.

To summarize, the potential of building a theory of context is that it helps us to understand what individual behavior is responding to. A theory of context in no way guarantees that we will know what people will do, but it gives us a working hypothesis about what could happen. It is for this reason that I find this framework compelling not only as an analytic tool, but also as a design tool.

Affordance to do what? One challenging thing about creating a theory of context that focuses on potential is that it is possible to do many different things in any given moment. One could think about an affordance to comply or not, to try or not, to work with others or not (the list is endless). For that reason, when attempting to design a theory of context, it is imperative to select a specific focus. In my work, I have focused on the nature of student engagement with content. This is a meso level focus; a macro focus might look at participation versus non participation or opposition (see Hand, 2010), while a micro focus might look at the nature of what, specifically, students understand about mathematical content (see Empson, 1999). A meso level looks at the ways that students are engaging with mathematics itself, characterizing that engagement in terms that could be applied across mathematical content. Specifically, I have considered four types of engagement: procedural, conceptual, consequential, and critical (Gresalfi & Barab, 2011; Gresalfi, Barab, Siyahhan, & Christensen, 2009). Procedural engagement involves using procedures accurately (Rittle-Johnson, Siegler, & Alibali, 2001); conceptual engagement additionally involves understanding why an equation works the way it does. Consequential engagement involves recognizing the usefulness and impact of disciplinary tools; being able to connect particular solutions to particular outcomes. For example, students are engaging consequentially when they not only solve a problem by calculating the mean, but also explain what the mean tells them about the situation. Finally, critical engagement concerns agency in problem solving, and involves explicitly choosing particular tools and interrogating their impact on a solution. This way of engaging builds on the others; students can engage conceptually or consequentially without making an explicit choice about how they are solving a problem; realizing that their approach to a problem impacts its solution is a significant shift in engagement.

To illustrate the difference between these levels, consider the problem below (Figure 1), taken from Henningsen & Stein (1997), which they characterized as having the potential of offering high cognitive demand. At the macro level, this problem (assuming it is offered in the context of a classroom activity, with a grade attached to its completion), offers a strong affordance to attempt to complete the task. Not attempting to complete the task, in that context, would generally represent a significant breach of classroom expectations. At the micro level, this problem offers strong affordances to make connections between fractions, percents, and decimals, simply because the question includes the same question in these three terms. What's more, the problem offers a strong affordance for students to consider what .725 of the rectangle

actually looks like, as they are asked to shade this area in the rectangle. This task is made more challenging because the rectangle contains 80 squares, rather than 100, so students will have to do some actual mathematical work to determine what .725 of 80 actually is, and what it looks like in the representation.

1. a. Shade .725 of the area of this rectangle.
   b. What fractional part of the area is shaded?
   c. What percentage of the area is shaded?

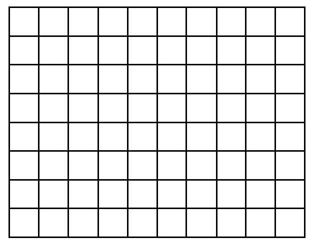

Figure 1: Sample Problem Offering High Cognitive Demand

At the meso level, we start to think about the nature of students' engagement with the problem—how they could go about solving it and what implications that might have for how they would understand it. A student could answer the question without considering the figure, as the fractional equivalent of .725 can be calculated procedurally, as 725/1000, and the percentage could also be calculated procedurally, by moving the decimal point two places to the right. These are standard procedures that are commonly taught to students to enable them to determine equivalency between fractions, decimals, and percentages. Thus, this problem offers strong affordances for engaging procedurally. However, the addition of the figure, and the request to shade the figure, creates opportunities for students to consider what .725 actually *looks like*. If the students were given a 10x10 square, this would be relatively easy. But because the square is 10x8, more calculation and thought is required. There are many ways that students could approach this task, but ultimately, successful completion requires both conceptual and, possibly, consequential engagement.

Conceptually, figuring out what .725 of 80 looks like requires moving beyond the rote execution of a procedure. The value of .725, or 72.5%, is not a quantity that is typically worked with. Students could solve the problem by figuring out what 75% of 80 is (60), and then estimating that it would be a bit less. Depending on the classroom context, this kind of solution might be acceptable and would surely demonstrate the students were taking up the affordance to think conceptually about what it means to take .725 of something. If a more exact solution was required, students might multiply 80 by .725. In either case, there is a strong affordance for students to move beyond simply using a procedure, either through estimating or calculating the area. As a brief note, the context of the classroom plays a significant role in the ways these affordances might be realized (Henningsen & Stein, 1998; Gresalfi, Barnes, & Cross, 2012).

Consequentially, the addition of the grid in this problem offers another strong affordance, which is to consider whether the solution that a student might come up with actually makes sense. Students often have trouble remembering the "rules" for decimal multiplication (for various predictable reasons, c.f. Martinie & Bay-Williams, 2003; Rathouz, 2011). Thus, the "simple" task of multiplication could yield a variety of solutions, few of which match onto the grid that the students are asked to shade. In this case, being asked to shade the area offers a

potential source of feedback for students, as it is impossible to shade 58000, 5800, or even 580 squares (the correct answer is 58). To make the strength of this affordance a bit clearer, contrast this task with one that asks to *determine* how much .725 of 80 is (without offering the grid). From a micro analysis (above), the two problems would offer identical affordances. From a meso analysis, however, the problems are quite different, as one contains a strong affordance to reason consequentially by testing out whether the calculational result actually makes sense.

Translating to Technology

Although the analysis of tasks is a well-worn area in mathematics education, the addition of technology is much newer. Technologies offer their own affordances, with the potential to support or thwart deeper forms of engagement. Potentially more problematically, most forms of technology offer not just different affordances for engagement, but also, more. Tools such as geometer's sketchpad or Tinkerplots create opportunities not just for productive engagement with mathematical content, but also offer a sandbox-like space that also allows for play and experimentation that can distract students from engaging with key ideas. More open technologies, such as video games, have the potential to offer even more affordances, both productive and not. In this context, with new tools that offer so many spaces for engagement, it is particularly important that designs be subjected to some kind of theory of context, with the goal of understanding what forms of engagement are truly likely to result.

Below, as an illustration, I offer an example of design changes that I made in the context of designing an educational videogame, which focused specifically on increasing the strength of an affordance to engage critically with content. These changes were made to the overarching dilemma of the game, which changed across three implementations to offer increasingly strong affordances to engage critically with content. As a reminder, critical engagement with content involves being reflective about the impact of a mathematical move on a designed context; in the case of statistics, one is engaging critically when they are able to discuss how the choice of a particular analytic tool (such as the mean) impacted what one could see in data, and how that might be different if a different analytic took (such as the median) was used.

Because the goal of this paper is to focus on design, I do not share detailed information about the implementations themselves. A much more extensive discussion of the evolution of the unit, details about design-based research, and specifics about the implementations can be found elsewhere (Gresalfi & Ingram-Goble, 2008; Gresalfi, in review).

Evaluating Technology in Terms of Affordances for Engagement

The curriculum discussed in this paper takes place in the context of an online, interactive and immersive videogame called Quest Atlantis (QA) (www.QuestAtlantis.org). QA is an educational videogame that uses a 3D multi-user environment to immerse children, ages 9-12, in meaningful learning trajectories across multiple disciplines. The QA virtual environment involves engaging a core dilemma that requires leveraging disciplinary content for its resolution. In some ways, these dilemmas provide a framework much like a well-developed problem or project might. Specifically, in designing these games, our goal is to *situate the learner* as having the intention of making decisions that impact the dilemma, *situate the content* as information that is legitimately required to resolve the dilemma, and *situate the context* as modifiable and responsive to learner choices (Barab, Gresalfi, & Ingram-Goble, 2010).

Interactive, immersive educational games create several opportunities for student engagement that are frequently lacking in traditional schooling. In particular, the immersive

context can embed students' inquiry in contexts that can have consequence, thus transforming targeted concepts from rules to be remembered to tools that can be applied. In addition, the fantasy of online videogames support pedagogically useful tropes that can serve as legitimate feedback for students' thinking; rather than having to look to a teacher for whether one's solution is accurate, the situational context can change in response to students' decisions, thus serving to push back on student thinking and solutions. In QA, students take on particular roles and engage various plot lines, which can evolve and change based on the choices that they make. In this way, students are central players in an unfolding storyline that requires participation in academically meaningful activities, either in the real or simulated world. Although students are "playing," their actions have more consequence than their "real world" interactions in schooling. In this way, well-designed videogames hold the potential to position students in relation to content in particular ways by affording different kinds of engagement, while simultaneously setting out a trajectory of participation that has implications for more enduring relationships with content and a new way of seeing the world (Gee, 2003; Lee & Hoadley, 2007; Shaffer, 2006).

Ander City

The statistics unit discussed here, called Ander City, was created to support students' engagement with the following content standards (NCTM, 2000):

- Select and use appropriate statistical methods to analyze data.
- Describe the shape and important features of a set of data and compare related data sets, with an emphasis on how the data are distributed;
- Use measures of center, focusing on the median, and understand what each does and does not indicate about the data set;
- Compare different representations of the same data and evaluate how well each representation shows important aspects of the data.
- Develop and evaluate inferences and predictions that are based on data.
- Propose and justify conclusions and predictions that are based on data and design studies to further investigate the conclusions or predictions.

The specific and somewhat unusual goal of the unit was to understand the role of statistical tools in allowing one to reveal—or hide—information. Students were afforded opportunities to consider how particular tools allowed some stories to be told, and not others. Although the exact storyline changed through cycles of design, as will be discussed below, the overarching issues remained consistent. Students were asked to make three crucial decisions for the city, all of which involved comparing two data sets that represented different companies or approaches. As an example, the first activity that students completed in all three revisions of the unit involved deciding which brand of bicycle the city should offer for rental in the park, based on which was the safest. All dilemmas were designed to support different conclusions depending on the statistical method leveraged for analysis (e.g. students might make a different recommendation if they calculate the mean of a data set than if they consider the mode or look at the distribution of the data set). As students help to redesign the city by making arguments for or against particular decisions, they engage with increasingly advanced statistical content, and are challenged to offer increasingly sophisticated explanations and justifications of their decisions.

To summarize briefly, looking across the iterations of the design (see Figure 2), we found that as we increased the strength of the affordance to engage critically with content, more students demonstrated critical engagement in their written recommendation.

Figure 2: Average total scores for Procedural, Conceptual, Consequential, and Critical Engagement across the Implementations.

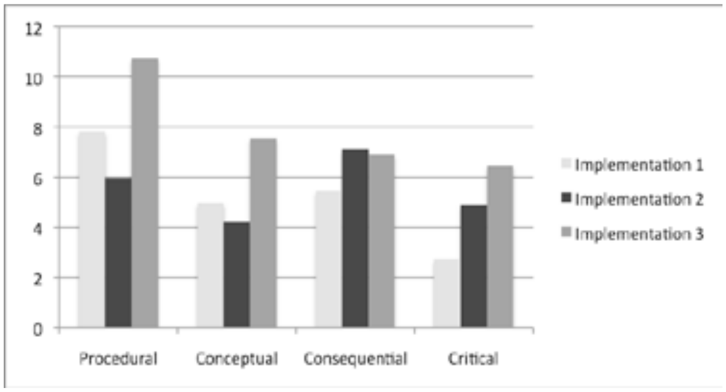

Table 1 summarizes the overall design decisions that were made. Below, I analyze the first and last of these decisions in terms of their affordances and share outcome data, particularly with respect to how those outcomes shaped our revisions for future designs.

Table 1: Overview of changes in narrative, intentionality, and outcome

Design	Narrative	Intention	Outcome
1	Mayor Enoch needs help making good decisions for the city.	Help Mayor Enoch	None
2	Mayor Enoch is being accused of deception, his opponent claims that he is making biased decisions that don't really benefit the entire city.	Defend Mayor Enoch against skeptics	Help Mayor Enoch keep his position
3	Mayor Enoch and Mr. Grant BOTH claim that they are making the right decision. They disagree with each other, although they both have data to support their positions. Is someone lying?	Determine which candidate is making better recommendations; or who might be lying.	Determine who will ultimately be elected mayor.

First Design

The storyline of the first version of the statistics unit centered on the fictional character of Mayor Enoch, mayor of Ander City, who claimed to need help. He was concerned that the citizens of the town were unhappy and were leaving the town. He felt that he had an obligation to make sure that he was making decisions that would make the city a better place to live, and would ensure that its citizens stayed. He thus needed assistance in making three crucial decisions: the first involved which brand of bikes they should offer for rental in the park, the second involved which brand of swings they should install, and the final issue involved the kinds of snacks they should make available in the snack cart that was adjacent to the playground in the park. These contexts became the decision points for students; they were invited to take a look at the data and make a decision to help Mayor Enoch based on their analysis of those data. The specific dialogues that occurred between Mayor Enoch and the player can be seen in Figure 3.

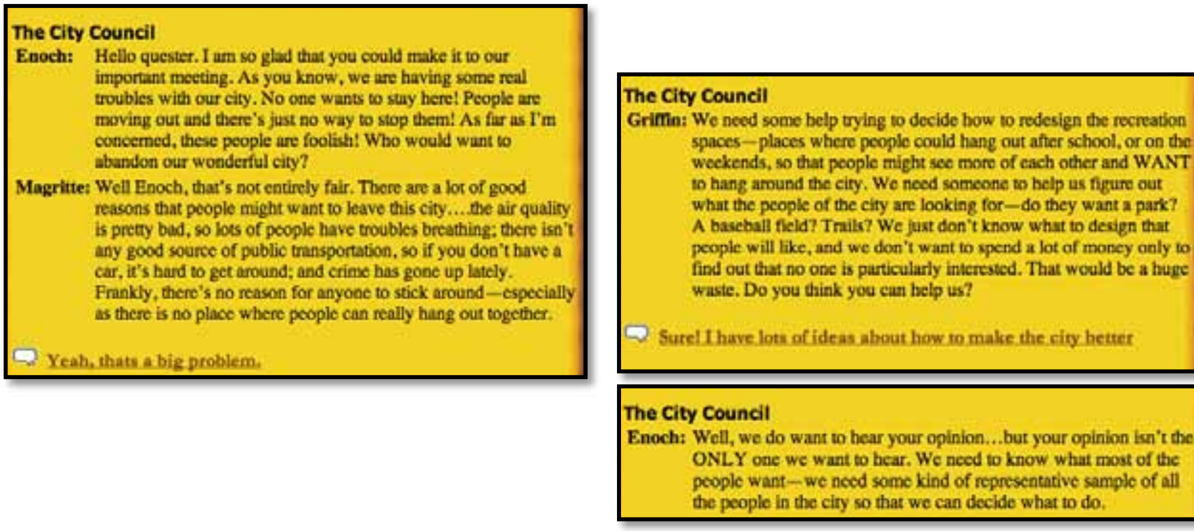

Figure 3: Narrative Framing for Design 1.

The narrative was designed with the goal of attuning students to the importance of making decisions that were *defensible*; decisions that could be justified with data. In creating a scenario wherein the Mayor of the city was in somewhat of a crisis, our initial conjecture was that the emotional salience of the situation would create a strong affordance not just to analyze data, but to be intentional about *how* those data were analyzed (critical engagement). We conjectured that this external audience (the citizens of Ander City) would raise the standards for students' recommendations, as they would take their activity to be about *convincing* rather than simply *complying* (Engle & Conant, 2002).

Uptake of Affordances. In this first implementation, we found that while students' critical engagement improved over the three decisions they made, there was still very little critical engagement overall. Specifically, students became accomplished at selecting one way to analyze the data they were given (the analytic method was always left open to the students), and then explaining what their analysis meant in terms of the situation (what we called consequential engagement). However, very few students seemed to realize that the way they analyzed the data impacted what they were ultimately able to say about those data. This suggested that what we had originally considered to be a strong affordance for engaging critically was in fact a fairly weak one; this was evidenced by the fact that so few students engaged in this way. This lack of uptake was in spite the fact that, in whole class discussions, they were able to compare and contrast solutions and therefore could clearly compare different solutions. In other words, we did not believe that there was a problem in students' effectivities for engaging these affordances.

Final Design. In our redesign, we attempted to raise the salience for the need for justification and considering both sides. We conjectured that the largely invisible audience of the citizens of Ander City did not provide a sufficiently strong affordance for engaging. Thus, we changed the narrative so that the mayor was running for re-election against a character who was maligning the mayor and his decisions. In the new scenario, students were asked to decide which candidate was making better choices for the city, and in particular, if one candidate was lying. We conjectured that shifting the role of the skeptic to the students themselves would serve to shift the agency for being critical directly to the students, as it would be impossible to consider who was

lying without evaluating both perspectives. In this way, the affordance for engaging critically was much stronger than in the initial design, as NOT engaging critically would constitute only a partial solution. The revised unit began with the following letter from another student in the town, seen in Figure 4.

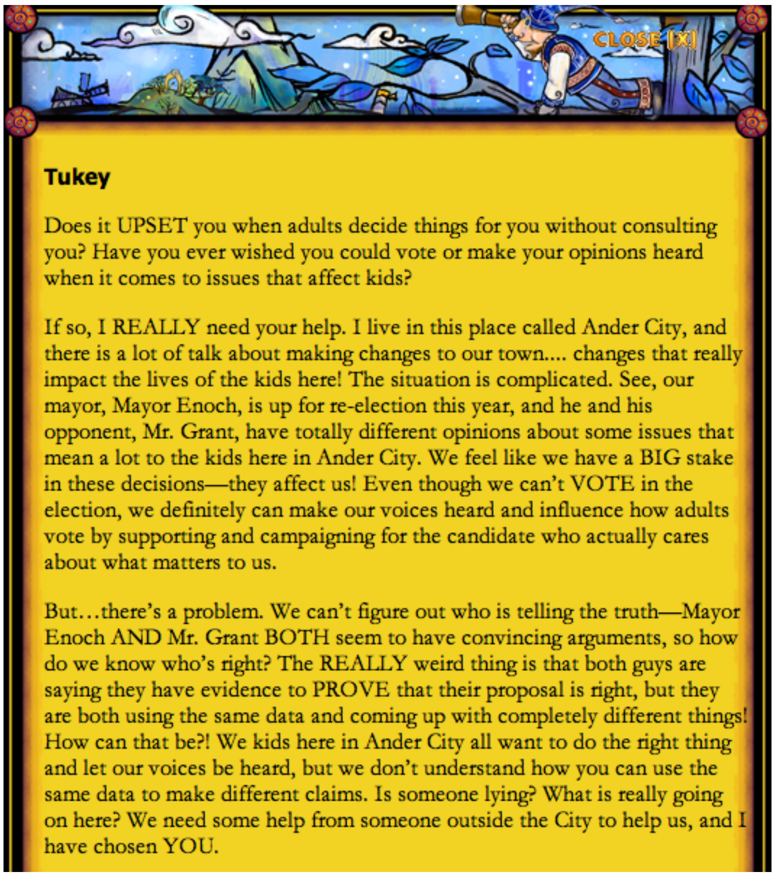

Figure 4: Narrative Framing for Final Design

Uptake of Affordances. In the final design, many more students engaged critically with the content, offering explanations of not only what they did, but also what they might have found if they had done something different. An example of an excerpt from a student's recommendation is below; the student explains that she used two different tools (total first, and then range), and justifies why she believes range is a better measure for the situation under consideration.

> "I analyzed the data by making a bar graph then added each 10 skids up and came out with speedy spokes for the answer as which is most reliable bike to stop soon enough before wrecking into something. But I just noticed the that the Speedy Spokes skid can be anywhere from 30 in. to 54 in. and the Rollin Steady skids were from 43 in. to 55 in. I would much rather be on a Rollin Steady bike because it is more consistent to what we are looking for here in Ander City so you don't run into the cars at stop sign. The reason why I chose range for the analysis is because I just thought that with a more consistent stopping bike that you wouldn't be worrisome about you stopping before the traffic or in the traffic this is why I chose the range for my analysis."

This student made it clear that she had considered the data in two different ways, each of which revealed something different about the data. Specifically, one way of looking at the data (total stopping distance) suggested that one brand of bike tended to stop sooner, but another way of looking at the data suggested that the other brand of bike was more predictable. These are both reasonable ways to think about safety, and thus it was left for the student to decide which analytic frame made more sense. Importantly, this student clearly felt that she had the agency to determine how to analyze the data, and was able to reason about what particular numbers (total stopping distance, range) actually meant in terms of the situation. Although not all students engaged critically even by the final implementation (the average score for critical engagement was 6.2/12, which is only over 50%), there was certainly a marked increase in the number of students who were able to approach data analysis in this more empowered, critical way.

Discussion

The examples above were intended to demonstrate how, in considering the strength of affordances, we can make sense of what students to in relation to what they have opportunities to do. In the case of the first design, very few students engaged critically in their written responses despite the fact that every single decision they were asked to make had two very plausible different solutions. One could imagine an analysis that suggests that students aren't able to consider two perspectives simultaneously, or, more insidiously, that students aren't thinking but are instead just following rules. Both explanations assume that there is a problem with students' interest or ability. Considering how engagement changed in light of the shift in the strength of the affordance to engage critically, a different interpretation is possible; specifically, that students *are* able to engage critically when they have a reason to do so—when the affordance is sufficiently strong that taking it up is required to successfully solve the problem. The shift in engagement that we saw across implementations clarifies that there wasn't a problem with students' effectivities, but rather, that a stronger affordance was required in order for students to recognize it and realize it.

An important question to be posed of this framework is whether or how one might actually measure the strength of an affordance. Indeed, the design trajectory shared above demonstrates compellingly that it is difficult to know whether students will take up an affordance, and thus initial determinations of something as being "strong" might ultimately be mischaracterizations. To be sure, there are parameters that we can use to offer initial conjectures about the potential strength of an affordance, but of course this can only be seen by examining a task or tool in interaction. This might seem a bit of a tautology: an affordance is strong if someone takes it up, and someone takes it up if it is strong. But this is not the case. In understanding what someone does in relation to what they have opportunities to do, we cannot simply examine a single individual separate from the classroom context, nor can we examine a single moment in time. If only one or two students act on an affordance, we can reasonably assume that the affordance was weak. Therefore, initial considerations of the strength of affordances must be grounded in small-scale analyses that document patterns in participation. Following this close analysis, this framework can begin to be used at larger scales, allowing for consideration of how the performance of one group, or many groups, differs from other groups, and to what we can attribute that difference. It is in this way that this framework can begin to bridge the large gap between case studies and "big data."

All learning theories, despite their vast differences, define learning as a change of some kind. Considering the opportunities to learn framework, learning can be considered as a shifts in

students' sensitivities to affordances such that, over time, strong affordances for engagement are not required. A student who had had multiple opportunities to work on statistical data analysis by engaging critically might become increasingly sensitive to opportunities, thus requiring only weak opportunities to engage in this way (Gresalfi, 2009). Reconsidering learning in this way offers a different interpretation of success and failure, and, equally importantly, offers immediately actionable recommendations for students who are failing to engage mathematical content as we would like them to. Specifically, as demonstrated above, by subjecting a task, technology, or even small design decision to a consideration of the strength of its affordance, we can begin to develop conjectures about what students will do. Following data collection and analysis of student participation, we can develop a clearer understanding of how the context is contributing to what we ultimately see students doing, knowing, and learning.

Acknowledgements

The work discussed in this paper was supported with funding from the MacArthur Foundation and the Gates Foundation. The development and research of the Ander City unit occurred in collaboration with Sasha Barab, Adam Ingram-Goble, Edward Gentry, and Janis Watson.

EXTENDED NETWORKS: MATHEMATICS CLASSROOM COLLABORATION WITH MOBILE DEVICES

Tobin White
University of California, Davis
twhite@ucdavis.edu

This paper explores the potential of mobile devices to support novel forms of mathematics classroom activity. In particular, I consider two salient aspects of contemporary practice with mobiles—networking/communication, and picture taking—and explore technology designs that might exploit their potential for supporting related forms of mathematical practice. I present data from two cycles in a design-based research project focused on collaborative learning in classroom networks, one featuring graphing calculators, and the other using iPods.

Keywords: Algebra and Algebraic Thinking, Classroom Discourse, Modeling, Technology

Introduction

Modern mobile computing devices—smartphones, tablets, and the like—have rapidly emerged as central tools in the daily practices of many American youth. Moreover, they increasingly prevalent in the hands of k-12 students at school. According to a recent report, more than half of all high school students now bring a smartphone to school (Grunwald, 2013), and Los Angeles Unified, the nation's second-largest school district, plans to give an iPad to every one of its 650,000 students by the fall of 2014.

But what might this proliferation of new mobile digital tools mean for teaching and learning mathematics? Handheld computational devices, in the form of four-function, scientific and graphing calculators, have been commonplace in mathematics classrooms for years. So for math, the potential for instructional novelty more likely lies in the newer features unique to the latest generation of tools—internet connectivity, communication and information-sharing resources, photo and video capture capabilities, customized apps. Indeed, many forms of digital practices with mobile devices popular with today's teens have clear analogs with aspects of mathematical practice highlighted in current standards (White, Booker, Martin & Ching, 2012).

In this paper, I present results from an ongoing design-based research (Brown, 1992; Cobb, Confrey, diSessa, Lehrer, & Schauble, 2003; Design-Based Research Collective, 2003) program focused on using classroom networks of handheld devices to support student interaction and collaboration in secondary mathematics classrooms. In particular, I focus on two of these distinctive capabilities of contemporary mobile devices—communication and information sharing via wireless networking, and camera-capturing photo and video images—as resources for designing tools and learning activities that might have the potential to integrate informal digital and formal mathematical activity.

Communicating and Collaborating in Classroom Networks

Perhaps the most essential purpose of mobile devices, and the fundamental reason for their near-ubiquity among today's youth, is as tools for communication: talk, text, email, video chat, and social media interface. As such, these devices have the potential to facilitate learners' participation in critical aspects of mathematical activity. Recent national mathematics education frameworks such as the NCTM and Common Core practice standards have stressed the

importance of providing students with opportunities to organize and express their own mathematical thinking as well as critically examining that of others. In this spirit, promoting student participation in mathematically rich classroom discourse has been a central theme in mathematics education research and practice over the last two decades (Ball, 1993; Lampert & Blunk, 1999; Yackel & Cobb, 1996). Often, instructional activity in this vein takes the form of teacher-facilitated whole-group conversations in which mathematical meanings, arguments and standards of evidence are established collectively (see, e.g., Forman, et al., 1998; Staples, 2007). In other instances, students work in pairs or small groups on collaborative problem-solving tasks, and thus have opportunities to discuss ideas and strategies, negotiate and coordinate interpretations, and provide peer tutoring (e.g., Barron, 2000; Boaler & Staples, 2008; Moschkovich, 1996; Leikin & Zaslavsky; 1997).

Recently, several innovative research and design projects have begun to map out ways that handheld devices connected to local computing networks might support and enrich these forms of communication and discursive interaction in mathematics classrooms. Classroom networks can support students' agency and participation in collective mathematical activity (Ares, Stroup & Schademan, 2009), attention to and identification with dynamic mathematical representations (Hegedus & Penuel, 2008), and opportunities to draw on diverse cultural and linguistic resources for participating in classroom discourse (Ares, 2008). Likewise, networked handheld devices in small group collaboration can facilitate greater communication, coordination and negotiation among peers (Zurita & Nussbaum, 2004), and expand and enrich avenues for active participation in joint problem-solving activity (White, 2006; White, 2009; White & Pea, 2011).

Contemporary mobile devices offer the potential to extend these networks beyond the classroom to connect students, teachers, and community members even as they move across contexts. Networked devices offer new possibilities for interaction; they present ways of rapidly distributing information, exchanging ideas and constructing shared artifacts. Just as in-classroom device networks have powerfully demonstrated the potential for merging peer communication with dynamically linked mathematical representations (Hegedus & Moreno-Armella, 2009; White & Pea, 2011), connections between mobile devices that extend the sharing of mathematical objects and ideas beyond the schoolyard represent unique opportunities for blending learners' informal digital activity with conventional forms of mathematics classroom discourse. In particular, photos, videos and other artifacts or data collected outside the classroom using mobile devices may form a particularly powerful resource for supporting learner's efforts to find conceptual coherence between real-world phenomena and school mathematics—especially if those captured artifacts or data allow learners to make mathematical meaning of personally relevant objects and experiences.

The *Graphing in Groups* Design

To explore these possibilities, this paper reports on two implementation cycles of a design for collaborative mathematics activities using a classroom network. The learning environment described in this paper is one among a family of designs greated according to the guiding principle that the *social* should be mapped to the *mathematical*—that collaborative relationships among students should be organized around the mathematical relationships that the learning activity seeks to help students understand (Stroup, Ares & Hurford, 2005). These designs have two primary pedagogical objectives: 1) to link each student participant in a small group with objects in the shared space of the classroom network to make important mathematical relationships salient, and 2) to encourage collaborative interactions among students by posing

tasks and challenges that require participants to coordinate their individual contributions in order to jointly manipulate shared objects. We develop these activities using the NetLogo modeling environment (Wilensky, 1999) and HubNet network tools (Wilensky & Stroup, 1999) in concert with classroom sets of student devices–Texas Instruments graphing calculators or Apple iPod/iPads. This classroom network situates each student's device within a server-defined small group, and a screen projection from the server at the front of the classroom displays mathematical objects linked to both individual student devices and to student small groups. Exemplars of this approach include each member of the small group examining different dynamically linked representations of the same mathematical function displayed on their respective devices (White, 2006; White & Pea, 2011), transforming alternate sides of a shared equation (Sutherland & White, 2011), manipulating different vertices of a jointly constructed quadrilateral (Lai & White, 2010), or moving respective points in a shared graphing space in order to jointly manipulate a curve (White & Brady, 2010; White, Wallace & Lai, 2012).

In the present design, called *Graphing in Groups*, students are assigned to work in pairs. Each student uses the directional arrow keys on her calculator or iPod to adjust the Cartesian coordinate location of a point, which is displayed both privately on the student's device and publicly in a graphing window projected from the teacher's computer. Two pairs of students are assigned to each in an array of such graphing windows in the public space, as shown in Figure 1.

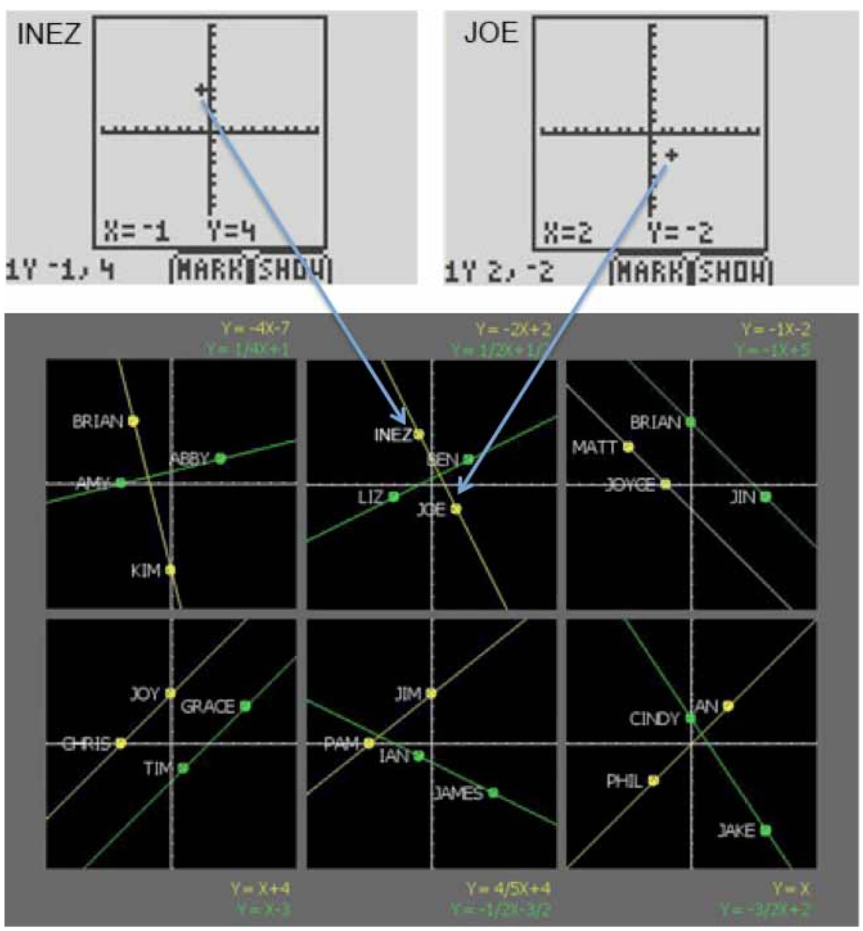

Figure 1: Two student Cartesian coordinate locations, on calculator screens at top, form a line drawn in a group window of a *Graphing in Groups* public display.

As each member of a pair marks a new coordinate location, the corresponding line between the students' respective points is dynamically redrawn and its slope-intercept-form equation updated in the public display. Classroom activities in this environment typically revolve around student pairs' successive efforts to construct lines with particular characteristics: a slope of three, an equation y=(4/3)x-2, x- and y-intercepts both equal to seven without either student placing her point on an axis, etc. In the iPod version of the Graphing in Groups design, students have the additional capability of sending photos taken using their devices up to the server, where they become the background for the group's graphing display (Figure 2).

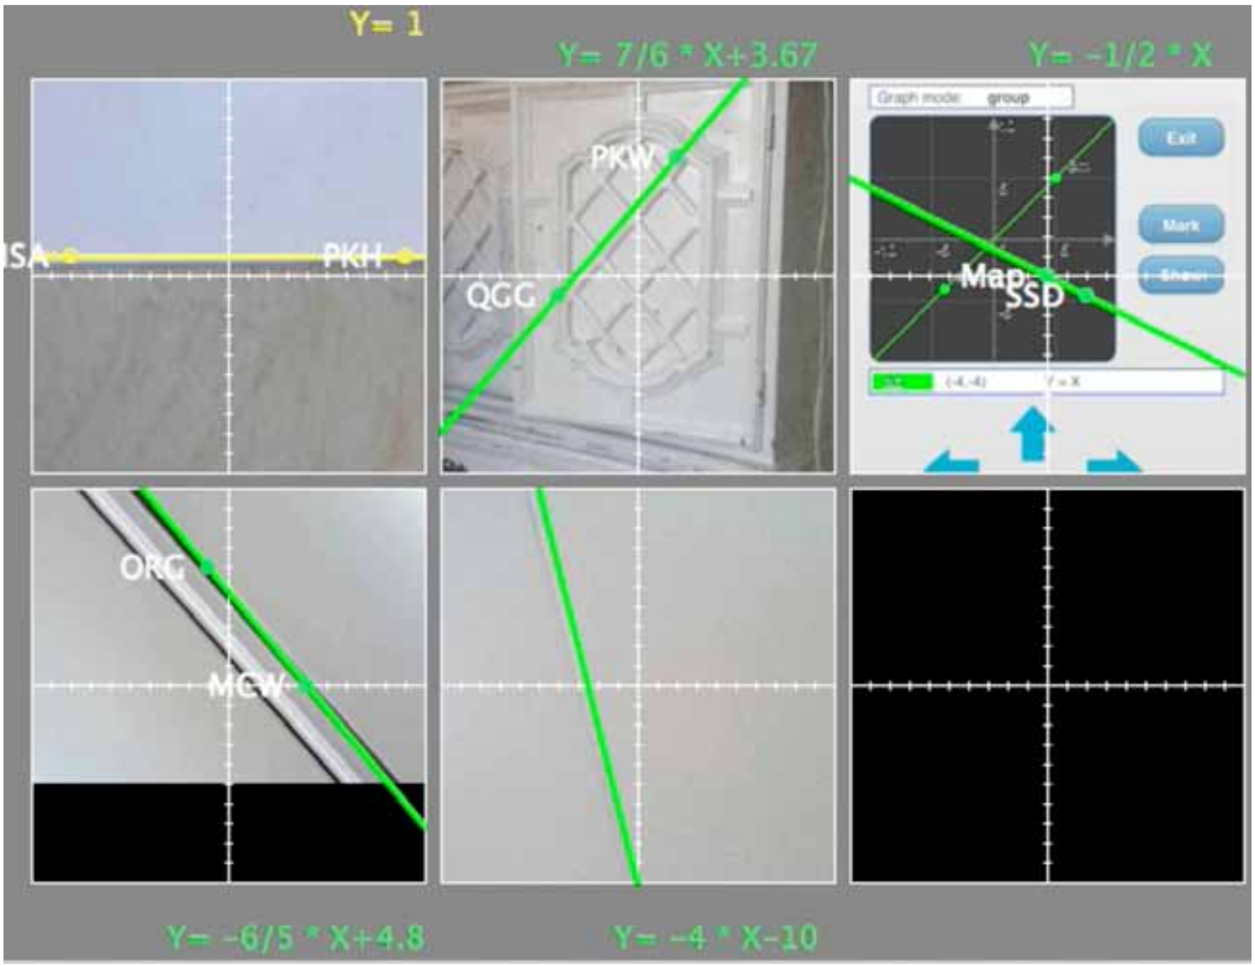

Figure 2: *Graphing in Groups* Display with Student Photo Backgrounds

Method

This paper presents data from two successive classroom-based design experiments using the *Graphing in Groups* environment at the same school site, first using the graphing calculator platform in the spring of 2010, and then again using the iPod Touch version in 2013. In the first cycle, six days of *Graphing in Groups* activities were part of a year-long project in which students participated in classroom network activities for a one-hour session each week as a supplement to their regular mathematics program. The author served as the teacher for all these

class sessions, and sixteen 9th grade Algebra I students participated regularly throughout the year. The second cycle was conducted as a shorter instructional unit featuring 4 sessions with a different group of sixteen students in a mixed-age cohort spanning grades 7 to 9. Two other researchers shared teaching duties with the author in this second study. Two to three student pairs in each class were selected as focus groups and videotaped during all activities. All screen states of the public computer display were recorded as a video file for each class session, and an additional camera with a wide zoom setting captured this projected display along with the whiteboard at the front of the room, as well as whole-class discussions and other teacher moves.

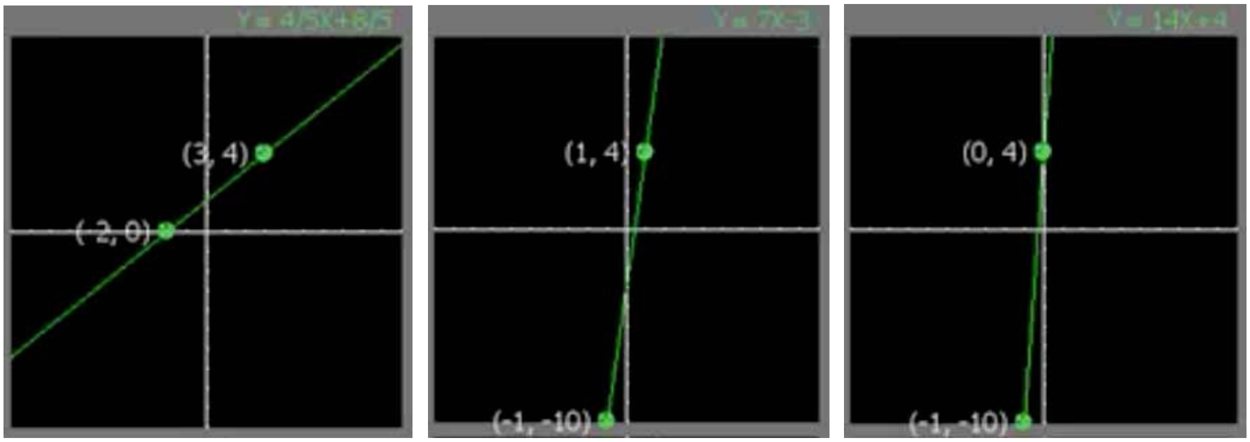
Results

To illustrate the kinds of mathematical activity supported by classroom networking tools, I will detail two brief episodes of classroom interaction as students worked together with the *Graphing in Groups* design. The first episode, taken from the study cycle featuring graphing calculators, highlights some of the complex interactions among students, teachers and mathematical objects typical of this environment. The second episode, from the iPod cycle, examines the potential for bridging these classroom mathematics activities with mathematical and digital experiences drawn from outside the classroom.

Episode 1: Classroom collaboration—supporting connections within and across groups

Below, I present a sequence of three consecutive segments of classroom dialogue during a line construction task in *Graphing in Groups*. Together, these segments span just over two minutes of classroom activity, as students worked in pairs to create lines with as large a slope as possible given the constraint of points confined to a graphing window with x- and y-min=-10 and x- and y-max=10. The first segment focuses on two students, Monica and Jamal, as they begin this task.

1. *Teacher*: Now, I want you to make the biggest slope that you can.
2. *Monica*: The biggest slope that we can?
3. *Jamal*: Oh, ok, I know how to do this. [From his initial location at (-2, 0) (Figure 3), begins moving his point to the y-axis and then down].
4. *Monica*: You know how to do this?
5. *Jamal*: Yeah. Alright, watch. [Continues to move down to (-1, -10)].
6. *Monica*: Where am I going? [Begins moving right from (3, 4)]
7. *Jamal*: Alright, hold on, go back, go back, go back, go back… [Monica moves her point back to (3, 4)]. Closer, closer… to the left. Go left… alright, go back. [Monica moves her point to (0, 4), then back to (1, 4)]. Yeah, right there. Stay right there!
8. *Monica*: Right there?
9. *Jamal*: Mark it. Yeah. [Both students mark points to form the line y=7x-3 (Figure 4)].
10. *Monica*: Seven? I think I can make it bigger than that. [Moves one unit left, to (0,4), and marks to form y=14x+4 (Figure 5)]. Fourteen!
11. *Teacher*: Group 3 has a slope of fourteen.
12. *Jamal*: Yup. [Sets his calculator down on the table in front of him.]
13. *Teacher*: That's pretty big.
14. *Jamal*: I think that's the biggest, cause…
15. *Teacher*: You think that's the biggest you can make? Let's see if anybody can make it bigger.



Figures 3, 4 and 5: Successive Lines Generated by Monica and Jamal

In this excerpt, Jamal opened with the assertion that he “knows how to do this” (line 3), and quickly began to move his point down to the bottom of the graphing window, presumably seeking to maximize the Δy between their points. When Monica began moving right, he directed her back to the left, likewise decreasing the Δx (lines 6-7). When both students marked their new points to form a line with slope m=7, Monica proposed that she could “make it bigger than that,” moving left one unit to form a line with slope m=14 (lines 9-10). As the teacher announced to the class that their group had formed the steepest line yet (line 11), the pair appeared satisfied with their efforts (lines 12-14) until challenged by the teacher to “make it bigger” (line 15).

Successfully completing tasks posed in the *Graphing in Group*s environment typically involves students’ establishing and maintaining a shared understanding of a solution strategy involving how to move their respective points to jointly construct the desired line. Several common characteristics of student actions and peer interactions in this environment (some of which are elaborated in greater detail in White, Wallace & Lai, 2011) are salient in this opening segment. First, ‘inhabiting’ this mathematical space (Noble, Nemirovsky, Wright and Tierney, 2001) takes embodied and multimodal form; students working on these tasks tend to rely on the coordination of spoken utterances with electronic actions in the shared graphical space (as when Jamal invites Monica to “watch” as he moves his point downward in line 5, and Monica likewise asks “where am I going?” even as she begins moving her point to the right in line 6).

Second, students often accomplish this coordination through careful negotiation and sequencing of their respective moves, rather than simultaneous action. Thus Jamal narrates his own problem-solving efforts in lines 3 and 5, then directs Monica’s movements “back,” “to the left,” and “back” again in line 7, then prompts them both to “mark” in line 9; Monica likewise announces her own successive strategic move in line 10.

Finally, the public nature of the group’s graphing display allowed the teacher to join them in assessing the product of their work, both by pointing out the value of their slope to the rest of the class (line 11) and prompting Jamal and Monica to consider whether the slope could be steeper. The next segment explores this public, whole-class dimension of the activity in greater depth. To do so, we widen our analytic lens, zooming out from one student pair (Monica and Jamal, Group 3) to include two other groups (Group 1, Juan and Miguel, and Group 4, Felix and Byron) working on the same task in parallel. In Table 1 below, the utterances of the teacher and the simultaneous dialogue within each pair are synchronized over a 32-second interval. Figure 6

shows the state of the whole class display projected at the front of the room as the next segment begins, immediately following the Teacher's invitation in line 15 above.

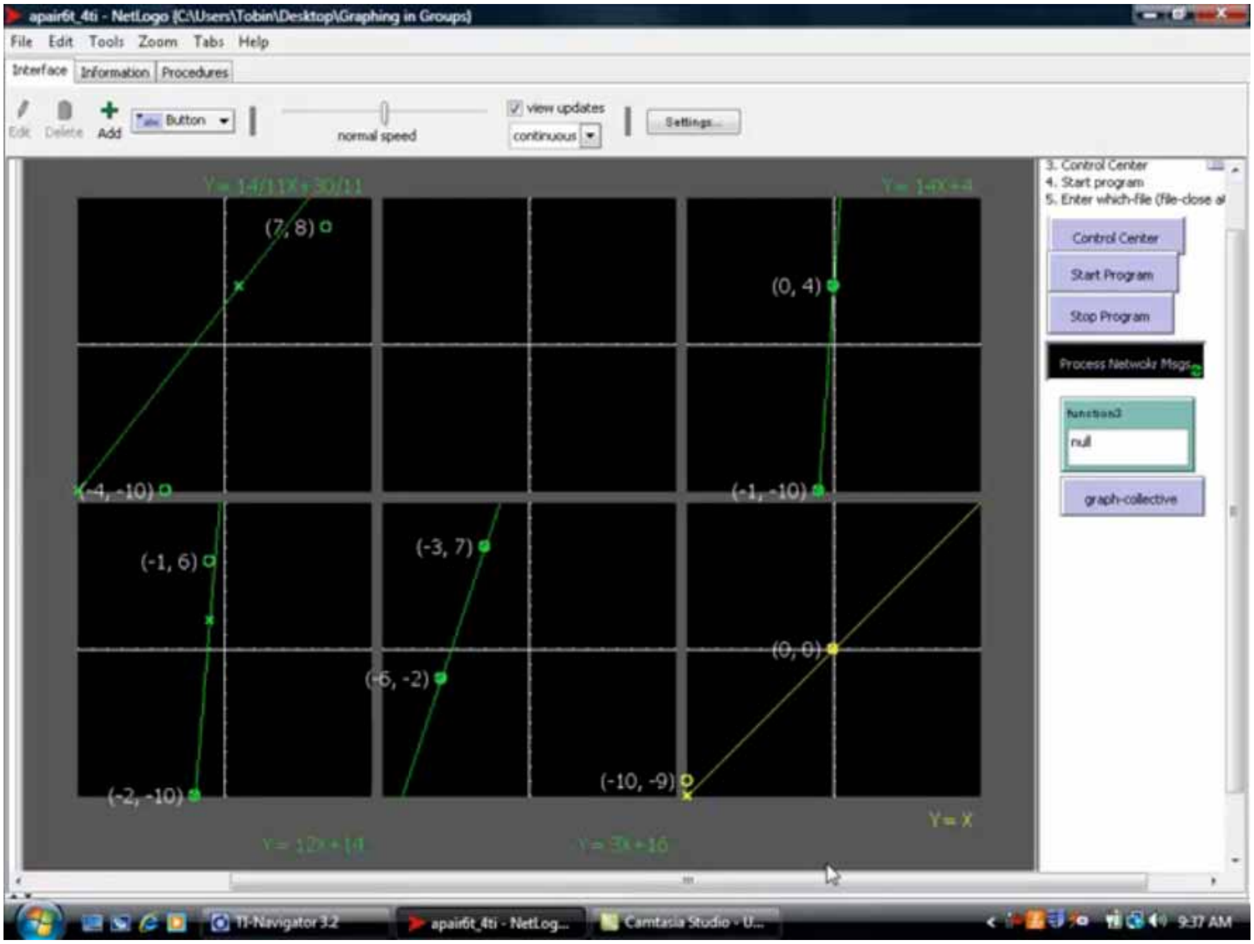


Figure 6: Graphing in Groups Whole-class display. Group 1 is in upper left corner, Group 3 in upper right, group 4 in lower left.

Table 1: Simultaneous Transcripts from Three Classroom Groups

Time (sec)	Teacher	Group 3	Group 1	Group 4
1	Group 4's got a slope of twelve.	*Monica*: [moving left to (-1, 4) as J moves right to (0, -10)]. Let me see, hold on, don't move.		[Byron marks at (-1, 10) to form y=20x+30]
2	Ooh, group 4's got a slope of twenty.	*Monica*: [as both students mark their new points] That ought to be a little bit better.		
3				[Byron punches the air in triumph]
4		*Monica*: Really then.	[J marks at (2, -10)] to form y=-14x+18]	
5		Go over to the, 10…	*Miguel*: Aww!	
7		[J begins moving to the left]		
8	Group 1, negative fourteen.		[J marks at (1, -10) to form y=N/A]	

9				
10	Group 3, negative fourteen.	[J marks at (-10, -10) to form y=(7/6)x+5/3]	[J marks at (0, -10) to form y=14x-10]	*Byron*: That's the lowest you can get.
11				
12			*Juan*: Go up. [M moves up one unit, to (7, 9)]	
14		[M marks at (2, 4) to form y=7x-10]	*Juan*: [Starts moving up] Go to the same one,	[F moves left and marks at (-3, -10)]
15			just go a little higher. [M begins moving left]	Byron: Just stop moving.
16			Same one you had.	
17		*Jamal*: Alright, hold on. Go all the way to the right corner.	*Miguel*: Oh, like right here [moves to (1, 9), directly over last mark	[F moves back to (-2, -10) and marks again]
18		*Monica*: [moving right to (7,4)] That's not going to be a very big slope, though.	at (1,4)] but higher? [moves up to (1, 10). J stops at (0, 2)]	
19		[M begins moving back to the left]	*Juan*: [M moves to (2, 10)] Yeah, right there.	
20		*Monica*: I have to be, like, closer to you.	[M moves back to (1,10)]	
21			*Miguel*: There.	[B begins drumming the desk with his thumb]
22		Jamal: [moving up] Oh, hold on, hold on. I've got an idea.	[J starts moving down]	
23			Juan: Wait, hold on, hold on.	
24			Yeah, right there.	
25		[J marks at (-8, -5) to form y=(9/10)x+11/5]	*Miguel*: Oh, do I mark it?	
26		[M marks at (-9, 4) to form y=-9x-77]	*Juan*: [still moving down] Yeah, mark it.	
27		*Monica*: That's only 9. [Begins moving right]	[M marks at (1, 10) to form y=20x-10]	
28		*Jamal*: [moves right] Alright, hold on. Go to the [waves finger to the right] right [points again] side.	*Juan*: [moving back down Yeah, you can't get higher than 20.	
29	Group 1's got 20.	[J marks at (-6, -5)]		
32		[M marks at (-3, 8) to form y=(13/3)x+21]		*Felix*: (to Group 1) Copycatters!

In the first two seconds of this segment, Monica and Jamal both tried further reducing Δx to increase the slope, producing a line with m=-14 even as the teacher announced Group 4's creation of a line with slope m=20. This news prompted different reactions from all three groups, as Byron thrust a hand forward in triumph (3s) while Monica mused "really then" (4s) and Miguel simply groaned (5s). Monica and Jamal then initiated a series of unsuccessful attempts at further increasing the slope of their own line, Jamal moving to (-10, -10) (10s) and directing Monica to the opposite corner (17s) even as Monica asserted that they should move closer together (20s). Meanwhile, Juan appeared to draw inspiration from Group 4's success, repositioning his own point at the bottom of the screen and then directing Miguel into a configuration that matched Byron and Felix's in order to likewise forma line with slope m=20.

This segment illustrates two additional characteristics common to *Graphing in Groups* classroom activity. The first is that the public display serves as a resource for the teacher not only to track the progress of all student groups as they work in their respective graphing windows, but also to comment on and provide feedback regarding their progress. The second is that the display also allows groups to attend to one another, sometimes modifying their own solution strategies based on their observations of others', as Juan appeared to do based on Group 4's work, and Jamal may well have likewise been attempting when he went to the lower left corner and directed Monica to the upper right after seeing a similar line constructed by Group 6 (lower right window in Figure 6).

In the moments that followed, Jamal and Monica continued to experiment with their own strategies until they converged on a solution:

16. *Monica*: I am just going to keep going until it makes it bigger. [Moves to the right]
17. *Jamal*: [Moves up and right, marks at (-5, -4)] Alright, hold on, let me go this way. [Moves to the left, marks at (-8, -4) as Monica marks at (-1, 8) and then (0, 8)] Holy crap. [Marks at (-9, -4), (-8, -4) again, and then at (-7, -4) as Monica marks at (-2, 10) to form y=(14/5x+78/5] Alright, fourteen…
18. *Monica*: [Moves left and marks, in quick succession, at (-3, 10), (-4, 10) and (-5, 10).] Don't move. [Marks at (-6, 10) to form y=14x+94, then moves to mark at (-7, 10) just as J marks at (-10, -6), forming y=(16/3)x+142/3] Why are you moving?
19. *Jamal*: Oh, sixteen…
20. *Monica*: [Marks at (-8, 10) to form y=8x+74] Eight.
21. *Jamal*: We had sixteen.
22. *Monica*: [Marks at (-9, 10) to form y=16x+154] Wait, now, sixteen.
23. *Teacher*: Sixteen, good, getting bigger.
24. *Monica*: [Marks at (-10, 10) just as J moves right and marks at (-9, -7) to make y=-17x-160] Stop it! Stop it!
25. *Jamal*: Seventeen, [marks at (-9, -8) to form y=18x-170] eighteen, [marks at (-9, -9) to form y=-19x-180] nineteen…
26. *Monica*: Twenty! (laughs) [J marks at (-9, -10) to form y=-20x-190] Twenty.
27. *Jamal*: Negative twenty, alright.
28. *Monica*: I think 20 is the biggest you can make it.
29. [Jamal, Miguel and the teacher have a brief exchange about the y-intercept]
30. *Jamal*: [marks at (-10, -10) to form y=N/A] Alright, hold on. Go right one
31. *Monica*: What did you do? Oh my God, Jamal. [moves right to (-9, 10), marks to form y=20x+190]
32. *Teacher*: Alright, there's another 20. Can anybody get bigger than 20?
33. *Monica*: I don't think it's possible.
34. *Jamal*: No, I don't think so.
35. *Teacher*: I don't think so either. Why don't you think so?
36. *Jamal*: Cause, that's the height [holds both hands in front of him, then waves right finger up and right, left finger down and left as if to mimic the respective positions of Monica's and his points (Figure 7)] like, the graph doesn't go any bigger.
37. *Monica*: The graph doesn't get any bigger.

Figure 7: Jamal's Gestural Depiction of the "Height"

Monica's opening comment sums up the approach she adopts in this last excerpt, moving two steps to the right and marking after each, and then reversing direction to systematically move and mark at every point from (-2, 10) to (-10, 10) (lines 17, 18, 20, 22, 24)—keeping on "going until it makes it bigger" (line 16). This kind of incremental variation represents another common strategy students use when trying to construct lines in *Graphing in Groups*, gradually tinkering with a line and feeling their way to a solution when they could not see a more direct analytic approach. Jamal, however, was not initially in synch with her efforts, instead moving and marking more haphazardly (lines 17, 18, 24) without consulting Monica. This failure to coordinate their efforts clearly frustrated Monica, who repeatedly asked Jamal to stop moving (lines 18, 24). By the time she reached the end of her leftward path, Jamal appeared to have recognized the progress she was making as he, Monica and the teacher all commented (lines 21-23) on their arrival at a slope m=16, their largest yet. Indeed, Jamal then took up the same iterative and incremental approach, moving to (-9, -7) and marking, then repeating the sequence for each step down to (-9, -10) as he and Monica called out the increasing (negative) slopes.

This segment thus highlights important additional aspects of action and interaction in *Graphing in Groups*; the embodied sense in which students act on these graphical objects through electronic point movements facilitates both individual exploration of the mathematical space, and nonverbal communication, as peers observe, react to and take up one another's patterns of motion. Moreover, the interdependence of the shared line on their respective

Cartesian points imposes constraints on individual action; students' common discovery that failure to coordinate their point movements undermines their individual problem-solving efforts and investigations, and thus builds a need for coordinated collaborative interaction into the learning environment.

Finally, Jamal's gestural activity during this episode further illustrates the embodied dimensions of learners' meaning-making in this virtual graphical setting. In the previous excerpt, Jamal's successive waving of his finger twice to the right in precise synchronization with the words "right" and "side" (28s) as he sought to orchestrate Monica's graphical movement highlighted the "semiotic bundling" of utterance, gesture and representation common to mathematical activity (Arzarello, Paola, Robutti & Sabena, 2009; Radford, 2003; 2009). Likewise in this segment, Jamal's carefully synchronized movements of each hand as he sought to explain why the line's slope cannot be greater than 20 while the points remain in the present graphing window (line 36) provide a visual rendering of the graphical situation, his hands abruptly stopping at the ends of their up- and downsweeps as if confined, just like their points, to the "height" of the available display (Figure 6). In this sense, these gestures with his hands at once appear to encapsulate the sequence of point movements necessary to construct the line, enact the relative positioning of his and Monica's points, and summarize the argument that the maximum slope has been achieved. That they are articulated via embodiment of two points, rather than a pitched hand or forearm to display the resulting line, suggests that the salient features of student action in this particular designed space provide specific resources for student reasoning about the corresponding mathematical space.

Episode 2: Extending Networks Beyond the Classroom

This section examines an excerpt from the work of another student pair in the *Graphing in Groups* environment, this time using iPods. This episode finds these students on their third day in the study unit. In the previous two days, they had been introduced to the iPods and the graphing tools; at the end of the previous session, the teacher gave a homework assignment in which he asked them to use their iPods to take photos of lines with different slopes to be shared and investigated when they returned to class. The excerpt below begins just after the teacher asked each pair to select one of their photos to upload to the network for display in their group's graphing window, and focuses on two students, Olivia and Jane, as they start this task:

1. *Olivia*: Okay, so these are the photos that I have [shows her iPod to Jane]. I have um…that…[opens Figure 8 on her iPod]
2. *Jane*: That would probably be good.
3. *Olivia*: That…[swipes through photo album to display Figure 9]
4. *Jane*: Is this stuff in your room?
5. *Olivia*: And that [swipes again to show Figure 10]. No, it's my sister's room. So which one do you wanna use, the one with the [holds hand up and makes a pitched line] stripes?
6. *Jane*: Yeah. Then we have different [trace a crisscross with her index finger] lines to go to. [A cropped version of the cabinet door from Figure 9 appears in Jane and Olivia's graphing window in the public display (Figure 11)].

Figures 8, 9, and 10: Candidate Photos on Olivia's iPod

In lines 1-6, we get some insights into the ways students made sense of this photo assignment. Olivia captured three images—one of a grid that might be a tile floor (Figure 8), one of a cabinet door (Figure 9), and one of a decorative string of globe lights hanging from wires at diagonals to one another (Figure 10). In each case, Olivia seems to have made a point of seeking out not just a single line to photograph, but multiple lines in parallel, perpendicular and/or skewed sets. In other words, she chose scenes that allowed her to fulfill the requirements of the assignment (find lines with different slopes) within a single image. She and Jane then further applied these same criteria to select the second image because it had the most pronounced slanting and "different lines to go to" (line 6).

As students' photos began appearing in the public display, Jane and Olivia proceeded to construct a line that matched one of those on the cabinet door:

7. *Jane*: [begins moving her point up and down along the y-axis, from the origin]
8. *Olivia*: What do you think the great…? [Jane pauses her point at (0, 3), right at the intersection of two lines in the photo image. Olivia begins moving left, approaching one of those two lines] Let's do the biggest one right [moves left again to (-4, -2), so that her point is now directly over the same line as Jane's] there.
9. *Jane*: This one?
10. *Olivia*: Like that?
11. *Jane*: Mark it?
12. *Olivia*: You can go higher if you want. [Olivia moves her own point up one unit] You see—you see where I am? Go on that line. You should go probably up two [Jane moves her point up two units to 0, 5) and then across, like…I don't know…one, two,…
13. *Jane*: [moves to the left] Like that?
14. *Olivia*: No, across the other way.
15. *Jane*: [laughing at the picture that just appeared in Group 3's window, moves right to (1,4)]
16. *Olivia*: One more. Go up.
17. *Jane*: [moves over and up to (2, 5), then back down] Ah!

18. *Olivia*: It's okay. [Takes the iPod from Jane and moves her point to (3, 7), hovering just above and beyond the tip of the line on the cabinet door in a position that matches Olivia's own relative to the other end of the same line]. There we go. [returns the iPod, then picks it up again to mark on it and then on her own to form y=(8/7)x+3.57 (Figure 11)]

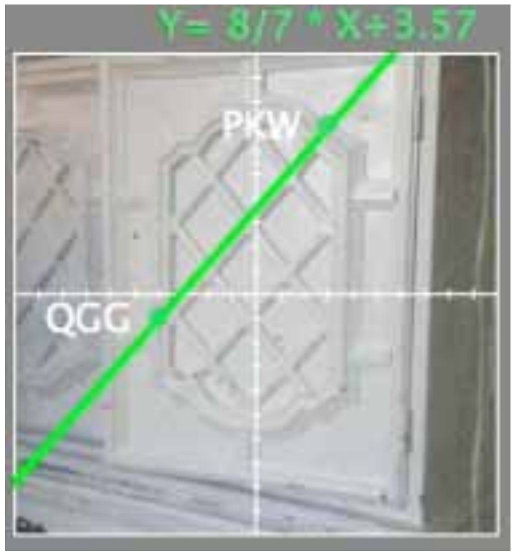

Figure 11: Olivia and Jane's Graphing Window with Cropped Photo Background

Beginning in line 7, we can observe how these students set about making mathematical sense of the images they collected. In particular, they were quick to identify one of the longest line segments in their selected image (line 8), and to use it as a frame of reference for forming their own *Graphing in Groups* line. Importantly, their efforts in this segment do not reveal substantive reflection on or interpretation of the slope of the line they constructed or its relationship to the photographed image. Moreover, and in contrast to the more open-ended and more collaborative process through which Jamal and Monica sought to make the "biggest slope" they could in the previous episode, this segment depicts a relatively closed mathematical task, and a cooperative process in which one student—Olivia—took most of the initiative and did most of the work, directing Jane where to move and mark (lines 12, 14, 16), and even taking her iPod to complete the final steps herself (line 18).

Discussion and Conclusion

This paper offers a detailed look at the nature of classroom interaction and collaboration in the context of a local network of mobile devices, as well as a more cursory glance at the possibilities for extending that classroom network to incorporate and support mathematical investigation of material such as photos. The first episode illustrates several key elements of student participation in the *Graphing in Groups* environment: that accomplishing line construction tasks in this environment involves coordinated action between participants, that achieving that coordination can require careful and complex orchestration of utterance, gesture, and electronic action, and that shared constructions dynamically displayed on a public screen affords additional layers of both teacher orchestration and peer interaction. The second episode reveals some of the possibilities and the challenges associated with integrating student-generated

images into this environment: they clearly yield personally relevant contexts to which learners bring their own aesthetic and mathematical lenses, and they clearly also require carefully constructed tasks that scaffold students' mathematical interpretations of those images and their collaborative interactions around them.

While the calculator version of this classroom networking design has been extensively studied and implemented in a variety of classrooms over several years, the iPod version and its photo and other extensions are still in a pilot phase. Our research group at UC Davis is actively developing these and other tools and accompanying classroom learning activities. The photo activity described here, for example, represents what we see as a bridging activity to begin connecting students' engagement with linear graphs with their experiences with linear phenomena in a variety of settings; the next and more substantive phase in this learning sequence involves students capturing video of phenomena that vary linearly over time, and then use tools on their mobile devices—and mathematics—to analyze that variation in greater depth.

CONNECTING TEACHING AND LEARNING IN CURRICULUM ADAPTATIONS

Jeffrey Choppin
University of Rochester
jchoppin@warner.rochester.edu

This study of six teachers focuses on the ways they organized the classroom discourse, attended to student thinking, and adapted complex tasks from a Standard-based middle school curriculum. The study explores Cohen's (2011) premise that the knowledge teachers develop is related to their attentiveness to student teaching. This study explores the relationship between the extent to which teachers were successfully able to elicit and organize instruction around student strategies and their ability to productively adapt tasks in terms of being responsive and maintaining cognitive demand. The results show that teachers with the most student-centered discourse practices were also able to provide the most detailed justifications for task adaptations and to productively adapt tasks from the Connected Mathematics Program (CMP) curriculum.

Keywords: Instructional activities and practices, Classroom Discourse

The ways teachers attend to student thinking impacts the kinds of knowledge they are likely to develop. This poses a significant change for teacher educators, as Cohen (2011) notes that most instruction "is marked by little close attention to learners' thinking and little effort to design instruction to advance it" (p. 27). Cohen attributes the rareness of attending to student thinking to the inherent uncertainty associated with listening and responding to another person's thinking, in contrast to the relative certainty and predictability of helping students to practice and remember predefined and narrow forms of knowledge. However, teachers' attention to how students make sense of mathematical concepts is, as Cohen notes, central to *attentive* teaching. Furthermore, Confrey et al. (2008) state that attentive teaching is an essential practice with respect to using the curriculum programs aligned with the National Council of Teachers of Mathematics (NCTM) Standards documents (NCTM, 1989, 1991) [hereafter referred to *Standards-based curriculum programs*]. Given the large U.S. investment in the Standards-based programs, it is imperative to research practices that lead to productive uses of the materials.

Cohen (2011)'s essential premise is that teaching needs to be connected with student learning to be effective. That is, teachers need to pay attention to how their teaching practices influence how students reason about academic content. He analyzes the relationship between teaching and learning by exploring connections between the knowledge developed by teachers, the organization of the classroom discourse, and the ways teachers attend to student thinking. He describes how teachers who engage in more expansive forms of discourse have opportunities to develop a greater sense of how students reason about content and can extend student learning to more complex forms of knowledge than would otherwise be the case, stating that "teachers who attend only a little or narrowly to students' knowledge constrain their opportunities to make intellectual connections that may advance learning" (p. 39).

The connections between teachers' discourse practices, their attention to student thinking, and their use of Standards-based curriculum materials are poorly understood. Most of the research on Standards-based materials focuses on early stages of implementation, which has limited the ability to show the longer term impact of teachers' instructional practices on their understanding of how the materials engage students. In short, Cohen's (2011) basic premise is

largely conjectural with respect to teachers' understanding and use of Standards-based programs. Consequently, this study explores Cohen's conjecture that there is a connection between teachers' discourse practices, their attention to student thinking, and the ways they design instruction to intentionally provoke forms of student learning. The study focuses on the ways that teachers' attention to student thinking is not only helpful in the moment but is associated with more productive uses of the materials over time. The study is set in the context in which an NSF-funded middle school curriculum was implemented, building from the idea, as Confrey et al. (2008) note, that Standards-based programs were designed to be sensitive to the ways teachers build instruction around student thinking.

Curriculum Adaptations

Adaptations to tasks as represented in written materials are inevitable as they are transformed in dynamic classroom contexts (Remillard, 2005). Spontaneous adaptations – those that happen during enactment – are influenced by the teacher's ability to purposefully improvise on the fly, which has been shown to be a high-capacity practice. In this study, the focus is on adaptations to curriculum materials that occur prior to enactment, as teachers use and adapt written materials to plan lessons (Remillard, 1999; Stein, Grover & Henningsen, 1996). In these planned adaptations, teachers often tinker with written tasks in ways that are intended to improve the efficiency with which students are able to complete tasks, but which neglect the conceptual development of the lesson (Kennedy, 2005). Other adaptations are in response to constraints in the local context, often in ways geared toward easing the chCorwinges and logistical burdens of cognitively demanding tasks (Arbaugh, Lannin, Jones, & Park-Rogers., 2006; Keiser & Lambdin, 1996; Manouchehri & Goodman, 1998). Typically adaptations lower the cognitive demand of tasks by removing their ambiguous or difficult features (Doyle & Carter, 1998; Stein, Grover, & Henningsen), though teachers have been shown to adapt tasks spontaneously in ways that build on students' contributions and maintain task complexity (e.g., Lampert, 2001). Recent work in mathematics and science education has described teachers who make adaptations to tasks that are productive, in that they maintain coherence with the design of the curriculum, they maintain the cognitive demand of tasks, and they are responsive to the classroom context (Author, 2009, 2011; Author, in press; Brown & Edelson, 2003; Drake & Sherin, 2009; Roth McDuffie & Mather, 2009).

Methods

The Connected Mathematics Project Curriculum Materials

The Connected Mathematics Project (CMP) materials (Lappan, Fey, Fitzgerald, Friel, & Phillips, 2006) emphasize student exploration in chCorwinging tasks as a means of developing mathematical content and they are comprised largely of tasks that are designed to be implemented at a high level of cognitive demand. Tasks in CMP also frequently require substantial amounts of student justification and explanation. Each CMP unit is divided into four to five *investigations*, each of which consists of a task situation or context that serves to organize the investigation. Each investigation begins with an initial problem that focuses on the key mathematical concepts, followed by a number of related problems. The investigations are intended to follow a *launch-explore-summarize* sequence. The launch portion serves to familiarize students with the context and the mathematics as a means of priming student activity in the subsequent exploration, in which students engage with a task that can typically be approached in multiple ways. The summarize portion allows for various solutions to be

compared and for the teacher to emphasize the important mathematical aspects of the tasks (Lappan, Fey, Fitzgerald, Friel, & Phillips., 2004). An important feature of the CMP materials is that mathematical concepts are developed across a sequence of tasks, lending coherence that is typically lacking in U.S. curriculum materials.

The Teachers

The six teachers were selected from a larger video sample. Five of the six teachers had extensive experience with CMP, having used the curriculum materials for a span of five or more years, and all had attended multiple week-long curriculum-specific professional development institutes. The sixth teacher was in her second year of using CMP and had attended a number of professional development workshops, including a week-long institute in Michigan. Two of these four teachers, Audin and Baldeck, were a 6^{th} grade planning team, and the other three, Corwin, Knauff, and Walsh, were an 8^{th} grade planning team, though Corwin was only a part of the team for the school year in which she participated in the study. The sixth teacher, Durst, taught 7^{th} grade in Lakeville, a larger suburban district whose students typically scored lower than those in Brookline and who came from a greater diversity of socioeconomic backgrounds. All six teachers made minimal omissions to the CMP instructional sequences for which they were observed, rarely (if at all) supplemented with new activities. Furthermore, with minimal exceptions, the teachers followed the three-part format for each investigation, as recommended in the teacher resource materials. See Table 1 for a listing of the teachers, their grades, and the units in which they were observed teaching.

Table 1: Teacher, Grades, and Units in Which They Were Observed

Teacher	Grade	Units
Audin	6	Accentuate the Negative, Comparing and Scaling
Baldeck	6	Accentuate the Negative, Comparing and Scaling
Corwin	8	Moving Straight Ahead
Knauff	8	Say It With Symbols
Walsh	8	Say It With Symbols
Durst	7	Comparing and Scaling

Data Collection

The research team created *Unit Sets*, modifying the *teaching set* methodology (Cobb, Zhao, & Dean, 2009), which involves videotaping multiple lessons and using specific events or practices observed in those lessons as the basis of teacher interviews. The pre-unit interviews focused on a teachers' perceptions of the main instructional goals for the unit, the primary chCorwinges they anticipated in terms of enacting the instructional sequences in the unit, and the key tasks and representations that facilitated the learning trajectories within the instructional sequences. The video-stimulated interviews were based on a set of about 10 episodes, ranging from three to 15 minutes in length, selected by the researcher to provoke reflection about instructional sequences in the unit. The researchers generated a series of specific questions around each clip and compiled the questions and the video clips, which was provided to the teacher. The teacher then had an opportunity to preview the clips (usually a week), after which they were interviewed for 60-90 minutes.

Analysis of Task Adaptations

Planned adaptations are characterized in the study by the extent to which they align with the philosophy of the curriculum program, maintain or enhance the cognitive demand and

complexity of tasks, are justified by observations of how students interact with the materials, and ultimately how they provide opportunities for students to engage in mathematical practices. The cognitive demand of tasks was determined by the extent to which ambiguity regarding choice of strategy was maintained and by the extent to which the task emphasized connections to underlying mathematical concepts. For example, if a teacher provided explicit instructions beyond what was in the student text about how to complete a task, it was deemed an adaptation that reduced demand. Conversely, if the adaptation facilitated strategies that became to focus of whole-class discussions in ways that emphasized concepts, it was deemed an adaptation that maintained or enhanced demand. The justifications for adaptations were characterized by the extent to which teachers provided detailed accounts from past enactments to justify their adaptations or whether they simply evaluated a past enactment (i.e., "I tried the task as written in the materials, it didn't go well, so I changed it"). The adaptations were usually identified in the observations of the video data, which gave the interviewer the opportunity to question the teacher about the adaptation and rationale for the adaptation.

Analysis of Classroom Discourse

Building from research on Accountable Talk (Michaels, O'Connor, & Resnick, 2008), the project team separated the teacher discourse codes into two categories that highlighted different ways that teachers attended publicly to student thinking, *teacher probes of students*, and *teacher moves that highlight strategies*. In addition, there was a code for *student explanations*, which was used when students' contributions included evidence to support the steps used to arrive at an answer. The three codes in the *teacher probes* category included *probed student to explain reasoning*, *probed students to confirm/ clarify*, and *elicited comments on strategy*. The *probed student to explain reasoning* code was applied when the teacher asked a student why he or she approached a problem a certain way or asked for justification of a procedure. The *probed students to confirm/ clarify* code was used when the teacher asked a student to confirm if the teacher's stated interpretation of the student' strategy was accurate or when the teacher sought clarification of part of the student's strategy. The *elicited comment on student strategy* code was used when the teacher asked other students what they thought of a particular strategy. The three codes in the *teacher moves that highlight strategies* category include *recalled past strategy*, *expanded on student response*, and *displayed student strategy*. The *recalled past strategy* code was used when the teacher introduced a strategy that had been presented at a minimum of several exchanges earlier and sometimes from much earlier in the lesson. The *expanded on student response* strategy was used when the teacher's recounting of a strategy included new terminology or steps. The *displayed student strategy* was used whenever the teacher publicly displayed a strategy, either by projecting the student's work or by rewriting the strategy on the board.

Results

The Classroom Discourse

The evidence of student engagement was characterized by the frequency with which teachers displayed student strategies. Each teacher displayed student strategies in a third or more of the time, either by displaying the students' version of the strategy on poster paper or projecting it, or by rewriting key steps of the strategy on the board or overhead. These strategies were then discussed, either by the students or, more commonly, by the teacher, usually to highlight a particular concept or procedure. There were substantive differences in the frequency with which students provided explanations for the strategies. Similarly, there were differences in the ways

the teachers elicited explanations associated with student strategies, and in the ways teachers called attention to and organized discussion around student strategies, as shown in Table 2.

There were big differences in the extent to which students offered explanations for their strategies. Audin's and Baldeck's students contributed explanations substantially more often than the students of the other four teachers (two to fifteen times as often). The results in Table 2 show that teacher moves in the category of *teacher probed students* all were strongly associated with the frequency with which students provided explanations, which suggests that these moves were helpful in eliciting student explanations. In these instances the teacher explicitly asked students to provide evidence for their strategies beyond simply describing steps. Similarly, moves coded as *probed student to confirm/ clarify* frequently elicited warrants that were coded as explanations. Moves coded as e*licited comments on strategy* were strongly associated with the probing moves in terms of their frequencies, which might explain the association between the *elicited comments* code and student explanations.

The other teacher move highly associated with student explanations was *teacher recalled past strategy*. This move was used more frequently by Audin and Baldeck and thus its association with student explanations may be confounded with the probing moves. However, this code represents a slightly different phenomenon and stands in contrast with the *teacher expanded student response* code, which also involved teachers broadcasting or explaining a student response or strategy, but which was poorly associated with student explanations. In moves coded as *recalled past strategy*, the teacher re-introduced a strategy that had been presented earlier in the lesson. In this move, the teacher typically highlighted the mathematical features of a strategy or showed how different strategies were related. The temporal distance between the presentation of the student explanation and the teacher recall of that explanation stands in contrast with the more temporally proximate teacher moves coded as *expanded on a student response*, which typically immediately followed a student response and functioned to evaluate and revise that response. The *recalled strategy* showed how the teacher connected student explanations over time and used student explanations strategically to emphasize key mathematical points.

Table 2: Discourse Practices

	Student explanations	Teacher probes of students			Teacher moves that highlight strategies		
		Probed to explain reasoning	Probed to confirm/ clarify	Elicited comments on strategy	Recalled past strategy	Expanded on student strategy	Publicly displayed strategy
Audin	60%*	19%	17%	35%	9%	12%	52%
Baldeck	39%	16%	21%	30%	5%	29%	65%
Corwin	14%	11%	7%	14%	3%	6%	51%
Durst	12%	2%	9%	8%	3%	29%	41%
Walsh	10%	5%	0%	2%	2%	7%	47%
Knauff	4%	0%	6%	2%	0%	23%	37%

*The percentages refer to the number of one-minute segments a code appeared relative to the total number of one-minute segments for that teacher

The *teacher expanded student response* moves provides insight into the differences between the teachers in terms of how they focused discussion on student strategies, especially the four

teachers who most frequently deployed the move. When Durst or Knauff expanded on a student's explanation, they tended to 'hijack' the strategy, explaining it without seeking student input. A third teacher, Baldeck, especially in Comparing and Scaling, discussed the strategies as if she was the student, explaining the mathematics but doing so as if she was recounting the student's thought processes, particularly for unusual strategies in the Orange Juice task. The expansions of the fourth teacher, Audin's, involved adding terminology or concepts to the discussion.

Curriculum Adaptations

There were differences in the extent to which the task adaptations maintained cognitive demand, differences that were associated with the nature of the evidence used to justify the adaptations. In general, those adaptations that maintained cognitive demand were justified by detailed evidence from past adaptations, as noted in Table 3. Audin and Baldeck adapted 16 tasks, of which 11 were determined to have maintained or enhanced the cognitive demand of the tasks. For example, in a unit on integer addition and subtraction, the adaptations focused student attention on connections between various representations, between operations on integers and the absolute values of the integers, and on the connections between student strategies. For example, one adaptation involved having students record and compare the conjectures that emerged from the introductory tasks to the unit. The teachers helped to guide discussions around the conjectures toward recognizing patterns involving addition and subtraction of integers and the underlying operations related to a number's distance from zero (absolute was not yet formalized), with the ultimate goal of building toward establishing sensible and efficient algorithms.

Table 3: Planned Adaptations

	Number of notable adaptations	Impact on cognitive demand/ coherence with design	Nature of evidence for adaptation
Audin	Six	Five maintained or enhanced demand	Five were justified by detailed accounts from past enactments
Baldeck	Ten	Eight maintained or enhanced demand	Six adaptations were justified by detailed accounts from past enactments; four justified by minimal evidence
Corwin	Four	One maintained demand	Justified by minimal evidence or evaluation of students' ability
Durst	Three	All reduced demand	Justified by minimal evidence or evaluation of students' ability
Knauff	Two	All reduced demand	Justified by minimal evidence or evaluation of students' ability
Walsh	Four	All reduced demand	Justified by minimal evidence or evaluation of students' ability

For the other four teachers, only one of the 13 noted adaptations were determined to have maintained or enhance the cognitive demand, while the other 12 reduced the demand of the tasks. In most cases, the reduction in demand resulted from providing explicit procedures to complete the task or from breaking the task into smaller parts, reducing the ambiguity and opportunity to make connections.

Discussion

There was a strong association between eliciting and successfully organizing discussions around student strategies and the tendency to adapt tasks in ways that maintained the cognitive demand of the tasks. Furthermore, the teachers who adapted tasks productively (maintained demand) cited details of student thinking from past enactments to justify those adaptations. A possible explanation for this finding is that teachers with strong mathematical and pedagogical knowledge can facilitate productive discussions as well as productively adapt curriculum materials. While this is plausible, it is important to note that Audin and Baldeck rarely adapted tasks in the initial implementations of the tasks. On average, the adaptations were designed in the third year they implemented the tasks. Both Audin and Baldeck have discussion intensive classes, as indicated in Table 2. In addition to the data presented in Table 2, the practices of these teachers have been observed over a seven-year span and during that time their classroom discourse practices have consistently focused on student thinking. The data in Table 1 indicate two prominent traits for Audin and Baldeck, the teachers who were most able to elicit student explanations: they persistently probed students' thinking, and they more strategically expanded and recalled student strategies to maintain a coherent mathematical thread in the discussion.

The data suggest that a consistent focus on student thinking, as evidenced by the frequency with which students provided explanations, provides opportunities for teachers to develop a deep understanding of how students engage with mathematical ideas in the enactments of demanding tasks. Furthermore, these opportunities translate into productive adaptations by providing a rationale for deciding when to revise a task as well as guidance for how to revise it. The teachers in whose classes the students less frequently provided explanations often decided to revise a task based on the evaluation that the students could not complete it successfully rather than on a more detailed rationale; in those cases, there was little explanation as to why the adaptation would more successfully engage students with mathematical ideas. Instead, the goal was to make it more likely that the students could complete each part of the task, often in isolation of the other parts.

The results of this study have implications for mathematics educators and for districts who adopt Standards-based programs with the goal of transforming instruction. First, discourse practices play a role for teacher learning by providing opportunities for attentive teaching. These discourse practices include not only persistent efforts to probe student reasoning but also skillful expansion and recall of those strategies to make important connections. However, it is the probing practices that open up the opportunities to learn about student thinking and consequently provide objects for teacher attention.

A second implication is that without explicit attempts by teachers to connect their teaching practices to the ways student engage with mathematical ideas, it appears unlikely that teachers will adapt the materials productively. The teachers in this study who primarily evaluated whether students were able to successfully complete a task were also the ones whose adaptations primarily lowered the cognitive demands of the tasks. These teachers did little to elicit and probe student thinking, and consequently had little evidence on which to guide subsequent adaptations of the materials.

The third implication is that the teachers who engaged in the most complex enactments in terms of eliciting and building from student thinking were also able to productively adapt the tasks. This required a messier and more uncertain environment as the teachers needed to productively guide classroom discussions even as they interpreted student strategies and attempted to engage students in interpreting their peer's strategies. At times this was

cumbersome and slower-paced than the classrooms of the other four teachers and created some concerns about content coverage.

We report on some results from a multiyear development of new techniques and materials for teaching linear algebra. Our goals were to (a) to create a professional learning community across STEM disciplines, (b) to combine expertise in content and pedagogy in designing effective instructional practice, and (c) to use learning theories to support the conceptual alignment of content and pedagogical goals. In particular, our approach combines the use of domain-specific problems, APOS learning theory, and the development of the professional learning community. This set of practices was developed and deployed across four diverse institutions, in diverse linear algebra courses, and was effective across this diversity. We discuss the development of teaching materials, and present reflections from students and faculty which were shared during and after these "modules" were used in classes.

Introduction

Linear algebra undergirds a remarkably diverse array of applications, such as computer graphics, network theory, economic and growth modeling, demographics, and cryptology. Indeed, it is this wide array of applications that makes linear algebra courses so popular among both mathematics and non-mathematics majors. Popular courses do not automatically enjoy effective pedagogy, however; improving the teaching and learning of linear algebra is the subject of ongoing research. Based on some of our prior investigations (Martin, Loch, Cooley, Dexter, and Vidakovic, 2010; Vidakovic, Cooley, Martin, and Meagher, 2008), we hypothesized that linear algebra pedagogy can be most effectively advanced through a strategy based on: (a) creating a professional learning community of STEM faculty dedicated to creating classroom experiences drawing from a diversity of application domains; (b) providing collaborative support, drawing on expertise in both content and pedagogy, for designing effective instructional practice; which, together (c) ensure conceptual alignment between content and pedagogical goals through the use of theories of learning and instructional models.

To test our hypothesis, we formed a community of investigation we call **LI**near algebra in **N**ew **E**nvironments (LINE). While LINE rests primarily on the three planks above, we also envision and support local change toward a reflective, collaborative culture of teaching and learning among STEM discipline faculty. Through our approach to linear algebra pedagogy, we model both (a) the integration of theoretical mathematical content, applications, and learning theories, and (b) co-teaching and collaboration among faculty with expertise in a variety of areas including mathematics, computer science (an applications domain) and mathematics education. We posit that this approach provides an enhanced experience for students, allowing them not

only to achieve a deeper understanding of linear algebra but also to develop their ability to reflect on their own learning.

Background and Theoretical Framework

To connect application-specific content, pedagogical practice, and reflection, the LINE approach relies on an instructional methodology based on the Action-Process-Object-Schema (APOS) framework (Asiala, Brown, DeVries, Dubinsky, Mathews & Thomas, 1996). APOS is a well-developed framework for understanding how students develop mathematical concepts; in addition to a model of cognition, it provides an instructional model intended to facilitate student development of richer and more sophisticated understandings of mathematical concepts. The approach has three components: It rests on a *theoretical analysis* (called a genetic decomposition) of what it means to understand a concept and how learners construct new concepts. This leads to the design of *instructional treatment* focused on these mental constructions. Then, as they teach, instructors *gather data*, which is analyzed in the context of the theoretical perspective and used to revise both theory and instruction, as needed.

The faculty in the LINE project, working as a professional learning community (Hamos, Bergin, Maki, Perez, Prival, Rainey, Rowell & VanderPutten, 2009), began the project with a reading seminar in which the faculty jointly examined mathematics learning theories—including APOS and other theories of scientific learning as well as cognitive difficulties related directly to linear algebra (Sierpinska, Drefus & Hillel, 1999) and collaborated in the initial development of modules for linear algebra using approaches based on APOS. The professional learning community continues to foster faculty development through a combination of activities among the different colleges using videoconferencing and working meetings at each other's institutions. Faculty also co-teach the modules, videotape each other while teaching, observe student engagement, and use these videotapes and observations to reflect on the learning and teaching processes in the context of learning theories.

Sample Module

Due to page restrictions, we discuss two representative "modules" to illustrate LINE principles rather than present them. Sample modules can be accessed from the authors. We chose the first one as an application in linear algebra and the second one as a more conceptual, theoretical module. After each module, we share some observations of the students' learning experiences.

There are four colleges participating in line: an urban public university in a major Northeast city with about 15,000 students, a land grant public university in the Northwest with about 30,000 students, a private college in the Midwest with about 2000 students, and an urban public university in a major Southeast city with about 30,000 students. Across these varying settings, though, the modules developed share important commonalities. In accordance with the line perspective, at least two faculty members developed and implemented the modules at each site. The faculty members work collaboratively at each site, and across sites, to develop the modules and integrate them into classes. Most importantly, the modules share a common aim: to introduce topics in ways that bring students to reflect on what they are learning and to actively readjust their understanding as they are exposed to new concepts, building on what they know and using that knowledge to grasp new ideas.

Sample Module I: Dot Product Application

This module was given to students after they had been introduced to the concept of the dot product and its connection to the cosine of the angle between two vectors. The module uses the

dot product to assess if certain texts were written by a particular author by having students create frequency vectors based on "function" words, such as but, an, the, etc. and to find the similarity between these frequency vectors and those frequency vectors from a known original text by the same author in question.

Observations of Student Learning

The whole class discussed the module after it had been completed. Most students were able to successfully decouple the idea of similarity from magnitude. There was some student debate over the question of which vector would be "least similar" to u, with some students holding that –u was least similar (since it was in the opposite direction), and others holding that the perpendicular was least similar. One of the more important misconceptions that emerged from this discussion was that several students talked about using the dot product to measure the angle of *a* vector, rather than the angle between *two* vectors.

Most students successfully identified that two texts with the same frequency vector would be judged as being similar. However, most felt it sufficient to write an original paragraph and claim that, since they had just written it, it could not be by the same author (thereby missing the point that a third person would be evaluating authorship). Two pairs of students gave viable answers: nonsense paragraphs that consisted of nothing but the frequency words.

Sample Module 2: Linear Maps

Whereas many modules were developed by experienced math educators already conversant with the APOS model, this module was developed by a research mathematician in conjunction with the LINE project researchers. He chose linear maps as one of the central themes of his course and proposed a series of problems that students would work on at the start of the study of that material. Line project researchers helped the instructor refine his problems to a set that would be:

- accessible to students in his class prior to formal instruction in this component of the course;
- aligned with the APOS framework for concept development in mathematics; and
- useful to assess student understanding of the material as a guide to instruction.

The instructor participated in the reading seminar online with the other researchers during the summer prior to the course. He then wrote the module reflecting his new understanding of the APOS framework. His initial design goal was to create a series of problems which would scaffold the students' ability to address problems "that require increasing levels of understanding," moving from simple to complex. As we discussed his design, it was not difficult to relate his complexity-based conception to the hierarchy of the APOS framework. The module began with concrete examples concerning linear maps. It then moved on to proofs requiring students to show that a linear map existed between certain vector spaces.

Observations of Student Learning

Some students said that the proof techniques they developed while working on modules carried over into other upper level math courses, such as abstract algebra. Others said the modules helped them think abstractly. Several noted that they liked the concrete examples at the beginning of a module and how they would tie in with the more abstract questions later. They also found the whole-class discussion provided them with significant feedback that comments written on an assignment could not provide. They expressed confidence in their understanding of linear algebra topics and said their knowledge had been enhanced and deepened by the modules.

Students performed quite well on this module, which was the second completed during the semester. As would be expected, the first two questions were correctly answered by most students, any difficulties were with the last two questions. Individual student recollections about the course and this assignment after the end of the semester appeared to match well with their

performance during the course. For example, when asked to identify three important concepts in the course a successful student said, "Linear transformations form the basis for a large portion of linear algebra, and since linear algebra overlaps with a lot of other fields (both with math and outside it), and knowing basics like this are important." When asked whether he could still answer these problems, he responded, "Without my book or another reference, I'm sure I could do 1 and 2, and I could probably start the rest of them. If I were to use references though I'm confident that I could complete all the problems, although it would probably take me longer now than it would have at the end of last semester because I'd have to do some review." He concluded, "The assignments were generally helpful to learning the material."

Conclusion

Our final goal was to ensure conceptual alignment between content and pedagogical goals through the use of theories of learning, with an emphasis on APOS, and instructional models. We believe we substantially met this goal, and that it produced noticeable positive effects on student learning: students, prompted to reflect on their learning, volunteered their beliefs that the modules deepened their conceptual understanding.

This project has been more successful than our previous efforts; whereas before we attempted to create this conceptual alignment by offering parallel courses in math content and learning theory, now we focus on collaboration among faculty. The parallel courses didn't work as well, mainly because students didn't have time in their schedules for an extra class on learning theory. By concentrating on infusing learning theory into instructional practice, we were able to convey some of these ideas implicitly to students. Collaboration between mathematicians and math educators has been extremely valuable in rethinking instruction in upper-level math classes.

This approach appears to be surprisingly universal: the four institutional settings are quite different—in size, location, student population, and curriculum—but this mode of instruction has led to changes in all of them. Finally, this approach to designing instructional material is flexible. Not every module drew equally from the LINE principles; some emphasize applications, some were technologically enhanced, and some were like carefully-structured labs based on a text.

A CHARACTERIZATION OF TEACHERS' IMPLEMENTATIONS OF A MATHEMATICAL DECISION-MAKING CURRICULUM

Krista Holstein
North Carolina State University
kaholste@ncsu.edu

Karen Allen Keene
North Carolina State University
kakeene@ncsu.edu

The purpose of this study was to examine teachers' implementation of a specific mathematics curriculum and how their conceptions influenced this implementation. An innovative, powerful tool, known as "teacher logs," was used to examine teachers' implementations of the curriculum; a survey was used to study teachers' conceptions related to their implementations. Results suggest that teachers tend to implement the materials closely to the written text, but there was variety shown both within and among teachers. A relationship was shown between teachers' implementation levels and ***their*** *beliefs about mathematics and their beliefs about students. The results of this study reveal that teachers may or may not stray from the authors' intended curriculum, and whether or not they stray often relates to their conceptions.*

Keywords: Curriculum, Curriculum Analysis, Teacher Beliefs

When new curricula are developed, researchers, policy makers, and teachers often ask, "Do these materials work? Are these materials effective?" As a result, a committee was charged by the National Research Council (NRC) to determine the quality of curriculum evaluations. In their report, *On Evaluating Curricular Effectiveness* (NRC, 2004), the committee defined curricular effectiveness as, "how effective a particular curriculum is, and for whom and under what conditions it is effective" (p. 1). When determining curricular effectiveness, one important part to consider is teachers' faithfulness to the curriculum authors' intentions because if teachers do not implement the materials as the authors intended, they may undermine the effectiveness of the new curriculum. Specifically, implementation fidelity needs to be considered. Holstein, Dietz, and Keene (2010) defined implementation fidelity as "the extent to which a teacher implements a curriculum as the author intended, allowing for adaptation, supplementation, and improvisation by the teacher" (p. 2). The concept of implementation fidelity is not equivalent to teacher quality. That is, low implementation fidelity does not suggest poor teaching. Rather, researchers study implementation fidelity to determine the extent to which the teacher implemented the materials. This information can then be used, in part, to determine curricular effectiveness.

Recent research on implementation fidelity has emerged partly because teachers often transform the written curriculum into a form completely different from the authors' original intentions. One may ask, "Why does this transformation occur?" One explanation is teachers' conceptions (e.g., about math, teaching, students, or curricula) influence their instructional decisions. Therefore, when examining implementation fidelity, it is important to consider teachers' conceptions. We use the word "conception" in the way Lloyd and Wilson (1998) used it: "to refer to a person's general mental structures that encompass knowledge, beliefs, understandings, preferences, and views" (p. 249)

Context and Purpose of the Study

The context for this study is the NSF-funded Mathematics for Decision-Making (MDM) curriculum (Project DRL-0733137). The emphasis of this curriculum is on decision-making using mathematical models based on engineering concepts. The text contains large real-world

problem contexts that require multiple steps to solve and interpretation of the solution. The curriculum is intended for high school seniors who have completed two years of algebra and one year of geometry (or the equivalent).

The purpose of this study was to examine teachers' implementations of the MDM curriculum and how their conceptions influence their implementations. In particular, we studied how closely teachers' enacted curriculum aligned with the authors' intended curriculum. We also investigated teachers' conceptions that could bring their enacted curriculum closer or farther from the authors' intended curriculum. The particular conceptions we considered were teachers' (a) subject matter knowledge, (b) beliefs about mathematics, (c) beliefs about students, (d) beliefs about teaching, and (e) beliefs about curricular materials.

The research questions were as follows:

1. How do teachers' implementations of a mathematical decision-making curriculum align with the authors' intentions?
2. How do teachers' conceptions influence their implementations of a mathematical decision-making curriculum?

Research Background

The NRC (2004) developed a framework to define "what is meant by a scientifically valid evaluation study for reviewing mathematics curriculum effectiveness" (p. 36). It included three major components for curriculum evaluations: "(1) the program materials and design principles; (2) the quality, extent, and means of curricular implementation; and (3) the quality, breadth, type, and distribution of outcomes of student learning over time" (p. 4). Scientifically valid evaluation studies on curricular effectiveness should include all the components of this framework. In the present study, we examined the "Implementation Components" (the second major component) piece of the framework, with the understanding that future studies should include the other components of the framework to determine the overall effectiveness of the MDM curriculum.

One way to study the implementation components of a curriculum is to examine how the curriculum transforms from the written materials to what students actually experience in the classroom. Stein, Remillard, and Smith (2007) provided a framework for studying the transitions of the curriculum from its written form to its enacted form, as shown in Figure 1.

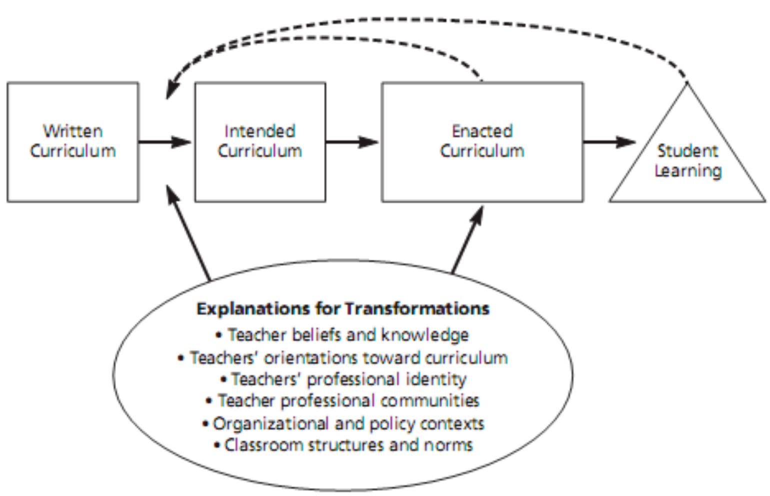

Figure 1: Temporal Phases of Curriculum Use (Stein et al., 2007, p. 322)

The curriculum begins as a written curriculum, which refers to the authors' original printed materials. Then, the curriculum changes into what the teacher intends to teach. This initial transformation occurs due to teachers' conceptions, goals, and contexts, as shown in the oval in Figure 1. Next, the curriculum transforms again into the enacted curriculum, which is the classroom implementation of curriculum materials. The enacted curriculum is also influenced by outside factors. Finally, student learning occurs. Therefore, it is unreasonable to measure the connection between the written curriculum and student achievement without considering the transformations of the curriculum. In other words, to determine whether a curriculum is effective, one must study whether the teacher is using the curriculum as intended by the curriculum authors.

To capture the implementation and to connect it to the authors' intentions, Heck, Chval, Weiss, and Ziebarth (2012) created two constructs: (a) the *mathematical storyline*, which refers to "which topics are addressed, at what depth different topics are addressed, and/or what learning goals and student expectations are pursued" (p. 69) and (b) the *pedagogical storyline*, which includes "which activities are conducted and how they are conducted in terms of openness or guidance, how students are grouped for instructional activities, and whether the patterns of interaction that are designed are actually pursued" (p. 70). These two constructs guided the methodology of this study (described below).

Moreover, one reason the transformation from written curriculum to enacted curriculum occurs is teachers' conceptions. Many conceptions influence teachers' instructional decisions and thus their implementation fidelity. Five conceptions which consistently emerged in the literature as influencing teachers' instructional decisions were examined in this study: (a) subject matter knowledge (e.g., Manouchehri & Goodman, 1998), (b) beliefs about math (e.g., Collopy, 2003), (c) beliefs about teaching (e.g., Stipek, Givvin, Salmon, & MacGyvers, 2001), (d) beliefs about students (e.g., Arbaugh, Lannin, Jones, & Park-Rogers, 2006), and (e) beliefs about curricular materials (e.g., Frykholm, 2004).

Methodology

In this paper, we present the quantitative portion of a mixed-methods study (see Holstein, 2012). To answer the first research question, an innovative tool called "teacher logs" was used. To answer the second research question, a survey was used, where the survey results were compared to the teacher log results. The participants came from the population of high school mathematics teachers who attended an MDM workshop ($N = 232$). Thirteen teachers completed at least one teacher log; 12 teachers completed the survey *and* at least one teacher log.

Teacher Logs

Huntley (2009) stated, "If we truly want to understand the relationships among textbooks, teaching, and student learning, it is critically important to develop curriculum-sensitive measures of implementation" (p. 357). In this study, we used teacher logs (Heck et al., 2012) as our "curriculum-sensitive measures of implementation." Teacher logs were developed by the first author of this paper for five chapters in the MDM curriculum (one teacher log per problem context and approximately three problem contexts per chapter, for a total of 16 logs). Each log contained a list of items for teachers to choose from, where each item illustrated an instructional choice. Every effort was made to include all possible implementation choices. Teachers checked off items that they did during their implementation of the curriculum, where each item (a) supported the authors' intentions, (b) went against the authors' intentions, or (c) was neutral. For example, the MDM curriculum authors included several in-text questions for students to answer themselves, either individually, in groups, or as a class. Therefore, the following item went

against the MDM authors' intentions: "I led a class discussion that covered the information out of in-text questions #1-2 (but did not explicitly ask these questions)." On the other hand, the following item supported the authors' intentions: "Students read and answered in-text questions #1-2 out loud or individually."

Teachers received four scores for each log: (a) a mathematical adherence score, (b) a mathematical focus score, (c) a pedagogical adherence score, and (d) a pedagogical focus score. The two mathematical scores were based on items that either supported or went against the curriculum authors' mathematical storyline; the two pedagogical scores were based on items that either supported or went against the curriculum authors' pedagogical storyline.

The mathematical and pedagogical *adherence* scores refer to how the teacher supported the authors' intentions. These scores were calculated using the following ratio, which yielded a score between 0 and 1:

$$\frac{\text{Number of fidelity elements enacted}}{\text{Total number of fidelity elements}}$$

A high mathematical adherence score means that the teacher addressed most of the content of the curriculum, while a low mathematical adherence score means that the teacher addressed little of the content of the curriculum. A high pedagogical adherence score means that the teacher addressed most of the instructional strategies of the curriculum, while a low pedagogical adherence score means that the teacher addressed little of the instructional strategies.

The mathematical and pedagogical *focus* scores took into account the fidelity elements as well as the items that went against the authors' intentions. These scores were calculated using the following ratio, which yielded a score between 0 and 1:

$$\frac{1 + \frac{\text{Number of fidelity elements enacted}}{\text{Total number of fidelity elements}} - \frac{\text{Number of other elements enacted}}{\text{Total number of other elements}}}{2}$$

A high mathematical focus score means that the teacher addressed more of the content of the MDM curriculum than other content, while a low mathematical focus score means that the teacher addressed less of the content of the MDM curriculum than other content. A high pedagogical focus score means that the teacher addressed more of the instructional strategies of the MDM curriculum than other instructional strategies, while a low pedagogical focus score means that the teacher addressed less of the instructional strategies of the MDM curriculum than other instructional strategies. Notice that the adherence score is one piece of the focus score.

Each teacher's mathematical adherence, mathematical focus, pedagogical adherence, and pedagogical focus scores were averaged. In the end, each teacher had four scores, regardless of how many logs they completed. These scores informed us about teachers' levels of implementation fidelity.

Survey

The purpose of the survey was to gather data on teachers' conceptions. The survey items were adapted from previously validated surveys, where each item measured one of the five conceptions included in this study: (a) beliefs about curriculum (items adapted from Spielman & Lloyd, 2004), (b) beliefs about math (items adapted from Fennema & Sherman, 1976; Perry, Howard, & Tracey, 1999; Suinn, 1988), (c) beliefs about teaching (items adapted from Perry et al., 1999; Spielman & Lloyd, 2004), (d) beliefs about students (items adapted from Fennema & Sherman, 1976; Suinn, 1988), and (e) subject matter knowledge (items heavily adapted from McDiarmid & Wilson, 1991). Note that the "beliefs about curriculum" survey items asked teachers about their beliefs about general curricula and were not specific to the MDM

curriculum; the "beliefs about math" survey items portrayed mathematics on a traditional to nontraditional continuum (Raymond, 1997). All items were on a five-point Likert scale, with the exception of the subject matter knowledge items, which were multiple choice.

Teachers received five scores on the survey (one for each conception). Then, a Spearman's Rank Order correlation was conducted to determine any correlations between the five survey scores and the four teacher log scores.

Results

In this section, we present the results for the two research questions. First, the teacher log results show teachers' implementation fidelity levels during their implementations of the MDM curriculum. Second, the correlations between the teacher log results and the survey results are offered to illustrate teachers' implementation fidelity levels related to their conceptions.

Implementation Fidelity

Averages for the four teacher log scores were calculated for each of the 13 teachers, regardless of the number of logs completed. Table 1 shows the overall results from these logs. In this table, the average score and standard deviation are given for each teacher for each of the four scores. This table also gives the following overall data: (a) the average of the teacher averages, found by averaging the average scores for the 13 teachers; (b) the standard deviation of the teacher averages, found by calculating the standard deviation of the average scores for the 13 teachers; (c) the minimum teacher average score; and (d) the maximum teacher average score.

Table 1: Teacher Log Results

Teacher Number	Number of Completed Logs	Math Adherence		Math Focus		Pedagogical Adherence		Pedagogical Focus	
		Score	SD	Score	SD	Score	SD	Score	SD
T1	12	0.5822	(.1529)	0.7179	(.1238)	0.5451	(.2428)	0.6867	(.1640)
T2	7	0.6638	(.1933)	0.8149	(.0999)	0.7794	(.1969)	0.8897	(.0985)
T3	4	0.7572	(.1478)	0.7328	(.0898)	0.8333	(.2357)	0.8479	(.0851)
T4	1	0.9375	(--)	0.9688	(--)	0.8333	(--)	0.9167	(--)
T5	4	0.9480	(.0392)	0.8832	(.1078)	0.8294	(.2243)	0.8678	(.0884)
T6	1	0.8889	(--)	0.9444	(--)	1	(--)	1	(--)
T7	8	0.7284	(.1466)	0.7749	(.1398)	0.6217	(.2033)	0.6949	(.1829)
T8	7	0.7215	(.1609)	0.7307	(.1434)	0.6643	(.3473)	0.7388	(.2407)
T9	2	0.5729	(.3388)	0.7388	(.2368)	0.5	(.2357)	0.6688	(.0913)
T10	1	0.9444	(--)	0.7103	(--)	0.8889	(--)	0.9444	(--)
T11	4	0.8547	(.1219)	0.8023	(.0916)	0.9069	(.1114)	0.8991	(.0837)
T12	2	0.9444	(.0786)	0.7961	(.1116)	1	(0)	1	(0)
T13	1	0.9444	(--)	0.6627	(--)	0.5556	(--)	0.7465	(--)
Average of Teacher Averages		0.8068		0.7906		0.7660		0.8386	
SD of Teacher Averages		0.1427		0.0925		0.1714		0.1182	
Minimum		0.5729		0.6627		0.5		0.6688	
Maximum		0.9480		0.9688		1		1	

To help make sense of these data, consider two teachers in Table 1 (recall that all scores were between 0 and 1). First, T1 adhered to only about half of the mathematical and pedagogical

intentions (mathematical adherence score of 0.5822 and pedagogical adherence score of 0.5451), but this teacher tended to use the MDM content and instructional strategies more than *other* content or instructional strategies (mathematical focus score of 0.7179 and pedagogical focus score of 0.6867). Second, T3 had relatively high scores, but the pedagogical scores (0.8333 and 0.8479) were higher than the mathematical scores (0.7572 and 0.7328). Thus, this teacher tended to be slightly less faithful mathematically than pedagogically.

When looking at the overall averages, the pedagogical adherence had the lowest average (0.766); this means that teachers did not necessarily use the instructional strategies intended by the authors and that they only used approximately three quarters of the instructional strategies presented on the teacher logs. However, the pedagogical focus score had the highest average (0.8386); thus, teachers used *other* instructional strategies less than they used the strategies intended by the MDM curriculum authors. The individual teachers' standard deviation values show variety within teachers; the overall minimum, maximum, and standard deviation values show that there was variety among teachers.

Conceptions Related to Teachers' Implementation Fidelity

Each teacher received a score for each construct based on the five conceptions (beliefs about curriculum, beliefs about math, beliefs about teaching, beliefs about students, and subject matter knowledge). From these data, a Spearman's Rank Order correlation was conducted to examine correlations between the teachers' implementation fidelity scores on the teacher logs and their conception scores on the survey. Table 2 shows the results from this analysis, including the correlation coefficients and the p-values (in parentheses).

Table 2: Correlations between Implementation Fidelity and Conceptions

	Beliefs about Curriculum	Beliefs about Math	Beliefs about Teaching	Beliefs about Students	Subject Matter Knowledge
Mathematical Adherence	.194 (.545)	.629** (.028)	.072 (.824)	.127 (.694)	.051 (.875)
Mathematical Focus	.111 (.730)	.004 (.991)	-.046 (.888)	.077 (.811)	-.462 (.130)
Pedagogical Adherence	.301 (.342)	.327 (.299)	-.231 (.471)	.659** (.020)	-.268 (.399)
Pedagogical Focus	.426 (.167)	.357 (.255)	.054 (.866)	.536* (.072)	-.317 (.315)

*$p < .1$. **$p < .05$.

The test revealed that there was a statistically significant correlation ($p < .1$) between mathematical adherence and beliefs about math, between pedagogical adherence and beliefs about students, and between pedagogical focus and beliefs about students. All other relationships were not significant.

The results for each conception are discussed here. First, there were no significant correlations between teachers' beliefs about general curricula and their teacher log scores. Second, teachers' beliefs about math were significantly positively correlated only with their mathematical adherence scores. That is, teachers with more nontraditional views of math tended to adhere to the authors' mathematical storyline. Third, teachers' beliefs about students were significantly positively correlated with their pedagogical adherence and focus scores. That is,

teachers with positive views of students and their abilities tended to enact most of the instructional strategies of the MDM curriculum (high pedagogical adherence score) and to enact more of the instructional strategies of the MDM curriculum than *other* strategies (high pedagogical focus score). Fourth, there were no significant correlations between teachers' beliefs about teaching on the survey and their teacher log scores. Fifth, there were no significant correlations between teachers' subject matter knowledge on the survey and their teacher log scores, but lack of subject matter knowledge was nearly negatively correlated with teachers' mathematical focus scores ($p = .13$). This means that teachers who lacked subject matter knowledge sometimes used the MDM content more than other content.

Conclusion

To examine teachers' implementation fidelity to the MDM curriculum, a new tool, teacher logs, were used. These results showed that teachers were generally faithful to the authors' mathematical and pedagogical storylines. This is not surprising as these teachers volunteered to implement the MDM curriculum and to take part in the study. However, there was variety shown both within and among the teachers. These results support previous research on implementation fidelity (e.g., Crawford, Carpenter, Wilson, Schmeister, & McDonald, 2012; Remillard & Bryans, 2004; Stein & Kaufman, 2010), and we extended this research by showing results in the context of the MDM curriculum.

To investigate the connection between teachers' conceptions and their implementation fidelity of the MDM curriculum, a survey was used, where the survey results were compared to the teacher log results. These results showed that teachers' beliefs about math were significantly positively correlated with their mathematical adherence; thus, teachers with nontraditional views of math tended to implement the content of the MDM curriculum—a nontraditional curriculum—with high fidelity. According to previous research, how teachers view the nature of mathematics, its origins, and its usefulness influence their curricular decisions (e.g., Collopy, 2003). Stein et al. (2007) explained that sometimes curricular materials "offer views of mathematics that conflict with those typically held in mainstream culture" (p. 353). Thus, teachers may stray from the written curriculum if the goals do not align with their beliefs about math. The results of this study confirmed that if the goals align, adherence is stronger.

In addition, the results showed that teachers' beliefs about students were significantly positively correlated with their pedagogical adherence and pedagogical focus scores; that is, teachers with positive beliefs about students and their abilities tended to support and to not go against the authors' pedagogical storyline. Alternatively, teachers with negative beliefs about students and their abilities tended to have lower pedagogical adherence and focus scores. Past researchers showed how teachers' beliefs about students play a role in their instructional decisions (e.g., Arbaugh et al., 2006; Remillard & Bryans, 2004). In particular, Arbaugh et al. (2006) found results similar to those in the present study, where teachers with negative beliefs about students and their abilities often strayed from the authors' intentions. However, many teachers in their study with such beliefs strayed from the intended *content* while the MDM teachers primarily strayed from the intended *instructional strategies*. Thus, the results from the present study complement and add to the research connecting teachers' beliefs about students to their implementation fidelity.

The results of this study have implications for many. For example, curriculum developers need to be clear about intentions and provide support for teachers. Teacher professional developers need to be aware of how teachers implement curricula and the conceptions that influence their implementations. Finally, future researchers should utilize the new, innovative

tool from this study: teacher logs. This tool is a powerful way to quantitatively study implementation fidelity.

TEACHERS' DECISIONS ON TASK ENACTMENT AND OPPORTUNITIES FOR STUDENTS TO LEARN

Ok-Kyeong Kim

Napthalin A. Atanga
Western Michigan University
achubang.a.napthalin@wmich.edu

Drawing on data from teachers using various elementary mathematics curriculum programs, this study highlights prevalent decisions teachers make to enact the task from the written curriculum and the potential of such decisions for student learning. In doing so, we examine teachers' instructional design decisions, especially those that teachers make when they face things that are not specified in the curriculum and when they see the need to fill in a gap in the teacher's guide in order to enact the task in their classrooms. We also examine whether such decisions can actually create opportunities for students to learn.

Keywords: Curriculum, Instructional Activities and Practices, Curriculum Analysis

Teachers make various *design decisions* when they use curriculum to plan and enact a lesson. First, they need to decide whether to use the task in the curriculum and, if so, how to use it. The curriculum usually includes various kinds of information regarding how to enact the task, such as questions to ask; representations, models, and strategies to use; a set of components of the task; and statements to make. Teachers decide whether to use, modify, or omit each of these provided in the curriculum. We call design decisions involved in this process *fidelity decisions*. Second, teachers need to determine a number of things to enact the task after fidelity decisions are made. Such decisions, which we call *enactment decisions*, need to be made especially when modifications are made or when the curriculum does not address things that may occur in a variety of situations during the enactment of the task. Even though we distinguish the two kinds of design decisions, they are closely related: fidelity decisions affect enactment decisions and vice versa. Sometimes one teacher decision can be both a fidelity and enactment decision (e.g., modifying a question suggested in the curriculum to build on previous learning). It is important to investigate teacher design decisions in terms of the two kinds of decisions and the relationship between them.

As a way to explore teacher design decisions, in this study we examine enactment decisions that teachers make along with fidelity decisions, especially when they face things that are not specified in the curriculum and when they see the need to fill in a gap in the teacher's guide in order to enact the task in their classrooms. We also examine whether such design decisions can actually create and increase opportunities for students to learn, given that teachers take specific actions to help students reach the goals they set for the students. Teacher enactment decisions can maximize the impact of the task on student learning and also can limit the impact, even though teachers have goals for student learning.

Theoretical Foundations

Teachers' ways of using curriculum materials are very diverse (Remillard, 2005). All teacher decisions involved in curriculum use, however, require determining whether to use the curriculum, how to use it, and to what extent. Often the term fidelity of implementation is used to help explain and elaborate on curriculum use. Fidelity of implementation has been investigated

from different perspectives, such as the philosophy and pedagogy of curriculum materials (Chval, Chávez, Reys, & Tarr, 2009), adaptations that maintain curriculum designers' original intent (Huntley, 2012), content coverage and presentation of content (Tarr, McNaught, & Grouws, 2012), the extent of coverage of curriculum materials (Tarr, Chávez, Reys, & Reys, 2006), and literal lessons versus intended lessons (Brown, Pitvorec, Ditto, & Kelso, 2008). Yet, investigations on specific decisions teachers make in individual lessons (e.g., whether to use particular questions and prompts suggested in the curriculum) have rarely been conducted, nor, in particular, how such fidelity decisions shape the enactment of the lesson.

The National Research Council (NRC, 2001) points out that opportunity to learn (OTL) is "the single important predictor of student achievement" (p. 334). Hiebert and Grouws (2007) explain that OTL depends on both teacher and curriculum materials. They further argue that creating moments in classrooms where students learn goes beyond exposing them to subject matter and learning goals. Stein, Remillard, and Smith (2007) argue that curriculum materials can influence students' learning, as they may contain mathematical tasks with cognitive demand that requires reasoning and problem solving. However, whether the task is used as intended depends on the teacher. Stein, Grover, and Henningsen (1996) find that even with tasks that require high cognitive demand, teacher actions can deprive students of opportunities to reason and think mathematically. Also, teachers may eventually change goals and mathematical points of the task (Sleep, 2012). These arguments may indicate that even though both curriculum materials and teachers are significant in creating opportunities for students to learn, the teacher's role seems even more critical. Many factors that can help create opportunities for the student to learn may be present in curriculum materials, and yet they may also lie fallow if not deliberately pursued by teachers during the enactment of lessons. Potential reasons may be partly because teachers make poor fidelity decisions, and partly because teachers need to decide a number of additional things on their own besides those specified in the written materials and tasks.

Research literature is replete with studies that inform us of modifications teachers make when engaging with mathematical tasks (e.g., Brown, 2009; Brown, Pitvorec, Ditto, & Kelso, 2008; Lloyd, 2008; Remillard & Bryans, 2004). Only a few studies, however, attempted to articulate teacher design decisions; even fewer studies examined the connections among modifications teachers make to the task (fidelity decisions), specific things teachers do to enact the task (enactment decisions), and kinds of learning opportunities students may experience (OTL). This study focuses on enactment decisions along with fidelity decisions and the potential of such decisions for student learning; in order to investigate enactment decisions, it is necessary to find out what fidelity decisions are made. In particular, questions that guide our study are: What enactment decisions do teachers make when they decide to use a task from the curriculum? In what ways do such decisions help create or increase OTL?

Methodology

This study is part of a larger study investigating teacher curriculum use – *Improving Curriculum Use for Better Teaching* (ICUBiT) project. The data analyzed in this study were drawn from this larger study.

Teacher participants and curriculum programs. Data were gathered from teachers in grades 3-5 using five different curriculum programs: (a) *Investigations in Number, Data, and Space* (INV), (b) *Everyday Mathematics* (EM), (c) *Math Trailblazers* (MTB), (d) Scott Foresman–Addition Wesley *Mathematics* (SFAW), and (e) *Math in Focus* (MiF). The first three were NSF-funded programs; the fourth was commercially developed; the fifth was originally

from Singapore and has gained popularity in the U.S. over recent years. We used a range of programs because we wanted to investigate teachers' approaches in using curriculum in general, not specific to particular types of curriculum, and what it takes to use curriculum programs effectively, regardless of types of programs. The participant teachers had at least three years of teaching experience and at least two years of using the same curriculum program. We intentionally recruited teachers with such experience because our aim was to investigate teachers' ways of using curriculum materials, not their learning to use curriculum materials, which is typical in novice teachers and those who are beginning to use a new program. This study drew on data from five teachers, one teacher per curriculum.

Data sources. The data we used in this study include classroom observations, teacher interviews (introductory and post-observation), and Curriculum Reading Logs (CRLs). Each teacher completed CRLs for each lesson that was observed: on a copy of the written lesson, the teacher indicated which parts they read as they planned instruction, which parts they planned to use, and which parts that influenced their planning, in yellow, blue, and orange highlighters, respectively. CRLs helped the researchers see plans for instruction and compare written and enacted lessons. Each teacher was observed for three consecutive lessons in each of two rounds. These enacted lessons were videotaped and transcribed. Also, each teacher was asked questions about his/her teaching experience and overall curriculum use at the beginning of the study, and then asked about specific teacher design decisions in the observed lessons after each round of three observations. These interviews were audiotaped and transcribed.

Data analysis. The main part of the data analysis was coding teacher fidelity and enactment decisions to examine the kinds of things teachers did that were not specified in the curriculum and the things that they did differently from the curriculum. We focused on one lesson per teacher, and the content of the observed lessons was primarily number and operations. First, we chunked Written (W) and Enacted (E) tasks using CRLs and videotaped lessons, and created lesson analysis tables that included W- and E-tasks side-by-side. We defined a task as a chunk of activity (including teacher and student activity) aiming at an apparent distinct goal or product. In this way, we examined each lesson in smaller chunks, rather than as a whole. This was because teacher goals, actions, and decisions may vary depending on the task. In each pair of W- and E-tasks, we identified teacher fidelity decisions (task components, questions, statements, representations, strategies, participation structure, time allocation, etc.)—whether each of these was used as recommended in the curriculum, changed, or omitted, or whether any new things were added. Also, we constantly compared the W- and E-tasks to identify enactment decisions by examining what teachers used from the curriculum, what changes they made, and what they did when things were not clearly addressed in the curriculum or when they filled in the W-task in order to enact it. Once each task was analyzed, we compared teacher actions across E-tasks, first within teacher and then between teachers, to develop preliminary codes and refined them as more tasks were analyzed. We did not include tasks that teachers adopted from outside the program they used, because of the focus of the study. Teacher interviews were analyzed to see teacher intention behind their decisions. After examining individual teachers, we searched for patterns in teacher enactment decisions and their potential impact on student learning.

Results

We found prevalent patterns in enactment decisions that the five teachers made. Regardless of the types of programs they used, they exhibited surprisingly similar patterns. W-tasks from EM and SFAW that included minimal directions and guidance regarding how to enact the tasks

and what to do left plenty of room for decisions that EM and SFAW teachers had to make. Even though MTB provided the most detailed guidance for teachers among the five programs, the MTB teacher did a number of things to fill in the gap in the W-tasks to enact them in her classroom. First, we describe the kinds of common enactment decisions and then discuss the potential of these decisions for student learning.

Teacher Enactment Decisions

When teachers used W-tasks to design a lesson, certainly there existed some uncertainty in those tasks. It was found that a number of things were not clearly addressed in the W-tasks, which were up to teachers' own decisions depending on their circumstances. Most of these decisions were intentional with particular goals in mind. The teachers clearly intended to help students get at the mathematics that they thought their students needed to learn from each lesson. To accomplish this goal, they attempted various actions that were not specified in the W-tasks: (a) having an extended launch of the task (including preview of the task, examples, detailed directions, etc.); (b) posing questions and prompts that students need to think about in order to do the task; (c) using additional representations or tools to help students understand something related to the task or to do the task; (d) making directions clear and giving specific guidance to help students complete the task; (e) providing modeling, demonstration, and explanation; (f) tailoring the task in a way that fits the classroom situation (or in the way that the teacher desires); (g) adding a new component to the task (e.g., summary or wrap-up discussion at the end of the task); (h) reviewing previous learning in relation to the task and in response to student thinking; and (i) connecting the task to previous/future learning. Table 1 includes examples of these teacher actions from an E-task of the MTB teacher's lesson. Note that having an extended launch requires many other specific decisions that are included in the table. Also note that these decisions are not mutually exclusive and there are some overlaps among them. In fact, when coding teacher decisions, we found one teacher action could involve multiple decisions. For example, ETA 1 in Table 1 not only helped students think about line of symmetry, but also led to review the concept they learned previously so students could use the concept to do the task.

Each of the five teachers tends to have an extended launch, especially for the main tasks of their lessons. For example, the MTB teacher and EM teacher spend 20 minutes and 25 minutes, respectively, for the launch of one main task they enacted. Interestingly, the W-task from MTB offers very specific guidance, whereas the W-task from EM provides minimal guidance with a bulleted list of three main steps and a couple of additional sentences before and after this list. Yet, both teachers spend a significant portion of their E-task helping students start the task. In such an extended launch, the teachers do a range of things, illustrated in the examples in Table 1. They want to provide very specific directions regarding what to do and how to complete the task. The teachers also ask questions and prompts for students to think about prior to working on the task. In this process, if opportunities come up, the teachers review mathematics concepts and ideas students have already learned that will be used in some way to do the task. They also model or demonstrate strategies, some small steps, or particular ways that are useful or efficient. Sometimes they add new components to the task. For example, the EM teacher provides a preview of the task that helps students see the components and expectations of the task and prepare to start. These are many more details than a curriculum could possibly include. In a sense, curriculum designers assume such teacher decisions and provide potentially necessary information and support for lesson enactment. However, certainly ambiguities exist in each curriculum. The more ambiguities, the more teachers' own decisions are needed to sort out such ambiguities and fill in the curriculum.

Table 1: Teacher Enactment Decisions

Decisions	Example teacher actions (ETA)
Pose questions and prompts students need to think about to do the task	1. How do we find lines of symmetry in general? 2. What else might you trace that would help you to keep track of things? 3. We're going to be using large numbers like in the thousands for addition; anyone have an idea on how we can do this?
Use additional representations/tools	4. If I give you something like this [a base-ten chart]. …… You do not need to use this chart. You can use this chart in your own way. You can do something else than what I have just suggested on the board there.
Make directions clear and give specific guidance to do the task	5. Do you think that there is something about that coat … that would help you be even more efficient than covering the whole coat? Is there something that we know about math that would help us be more efficient than covering up the entire coat? …… We're just going to do the one side, so we'd double it. Good, good.
Provide modeling, demonstration, and explanation	6. Ok, so you can fold your large piece of paper and again it's not going to be exact. You can also eyeball it. … What about if you wanted to, you have your neckline here, what could you, what tool could we use to find out where the middle was there? …… Right, you can measure this from here to here and you might find it's 10 inches and take the middle of, yeah! measure it from here to here.
Tailor the task in a way that fits in the classroom situation (or the way that the teacher desires)	7. We have flats, and then we have skinnies in the bottom. What would you use first? …… with all the bits out and count them up. Is that going to be the most efficient? What are we going to use first? …… This inside of the 2D object. Inside, cover the area. …… First you're going to start off with flats. Then what might we use next?
Add new components to the task	8. I would like to hear from just one or two people, something that you learned today that you didn't know.
Review concept previously learned in relation to the task or student responses	9. So, what is this line called? I am sure you have seen it. We have talked a little bit about it this year. 10. Finding the area, one example would be to find the area of the rug. So what is area? 11. How do we find lines of symmetry in general? …… You can fold it in half.
Connecting to previous/future learning	12. We're going to be doing addition and subtraction, or at least addition with these base 10 pieces. … And, you're going to be able to not just understand how to add or subtract, because you have been doing that for a long time. But we are going to get into some larger numbers. 13. Is there something that we know about math that would help us be more efficient than covering up the entire coat? And I am just going to put in your mind, it's one of the techniques that you use for Joe the Goldfish.

Now we will explain these various enactment decisions by using examples from the MTB teacher's lesson in Table 1. In a W-task from MTB, students are asked to find the area of a coat, using base-ten blocks (bits – ones, skinnies – tens, and flats – hundreds). The context given is that students are asked to find out how much material is needed to cover the front of the coat that will be worn at the school play. Students are expected to discuss specific procedures (e.g., tracing the outline of the coat, and covering half of the front and use that to find the area of the whole thing) and practical points (e.g., the coat should be zipped). The W-task also includes a note that some measurement error can occur. Students are expected to measure the area of their coat in groups of two or three. The written lesson containing this task is for two to three estimated class sessions. The guidance for enactment is provided in much detail. The E-task observed ends before students share the areas of the coats they measured and compare resulting 4-digit numbers (areas), which is done on the following day.

Even with the detailed guidance (see TIMS Project University of Illinois at Chicago, 2008, pp. 36-37), as shown in Table 1, the MTB teacher makes various enactment decisions to use the task in her classroom. She makes prompts very specific to help students work on the task in a desired way. It is efficient to measure only half of the coat and double it, and this strategy was mentioned in the W-task. The teacher not only brings up this strategy, but also makes sure students can use this strategy effectively by connecting a strategy students used in a previous task to this new task (ETA 13); posing questions to encourage students to think about the concept that is useful to do the task (ETA 1); reviewing the concept, line of symmetry, and how to find it (ETAs 9 and 11); providing demonstrations of how to find the line of symmetry (ETA 6); and giving specific directions on how to use the symmetry of a coat to do the task, i.e., find half the area of a coat and double it (ETA 4). She even has students consider a particular measure of the neckline (10 cm) and demonstrates what can be done using the outline of a coat on the board. One issue students may have in the task is keeping track of their record. When they place base-ten blocks to measure the area of a coat, the blocks can be easily moved from the correct place, which can make it hard to accomplish the task. In the W-task, it is recommended that students "trace the outlines of the base-ten pieces on the picture of their coats and figure out the area afterwards" (p. 37). The teacher emphasizes the importance of tracing blocks as students place them and discusses ways of tracing them in a very specific manner. Along with efficiency, she prompts students to consider that they should use flats first and then skinnies and bits (ETA 7). She even comments that, rather than tracing each bit individually, students can place and trace a group of bits and record the total number of those bits. She also encourages students to think about whether to place flats first and recommends that students start along the line of symmetry. These very specific directions and guidance are not clearly addressed or directed in the W-task, even though it does show a figure of outlines around the base-ten blocks, with flats used first along the line of symmetry. The teacher also suggests that students can use a base-ten chart to keep track as they trace blocks (ETA 4), and she demonstrates how to use the chart to record their work in progress and mentions that recording tallies (number of flats, skinnies, and bits traced) on the chart is one way to use this tool to complete the task. Finally, she adds a component that is not included in the W-task. She encourages students to reflect on their exploration by asking them to talk about what they learned in the task (ETA 8).

Opportunities Created for Student Learning

From the teachers' perspective, opportunities to learn may be envisioned in different ways. Even though the five teachers made some common enactment decisions, it seemed that these decisions resulted in different opportunities for student learning: nurturing or constraining OTL.

It is not that a particular teacher always nurtures or constrains OTL, even though there are some patterns in individual teachers. Depending on their focus of the task (they certainly interpret the W-tasks and determine their own goals to achieve by using the tasks) and decisions and actions they make, they create different kinds of OTL and can potentially limit OTL. Likewise, a particular enactment decision (e.g., giving specific directions) does not always nurture or constrain OTL. Depending on how teachers do it, for example, giving specific directions can enable students to focus on the mathematics they learn by removing unnecessary confusion, but it also can limit room for student exploration by eliminating students' struggles that may be important for them to experience. Students are expected to complete the task in an efficient way, and yet formulating procedures for students and equating particular types of problems with particular strategies seem to limit opportunities for students to think and make their decisions and then learn from the results of their decisions. They may experience difficulty or may struggle with their approaches, but this experience makes them learn the importance of certain things, such as keeping track and placing flats first, rather than bits, to measure the area of the coat.

An example of enactment decisions that constrains student learning is from the INV teacher's E-tasks about multiplication and division. This teacher focuses on key words throughout the lessons on multiplication and division by posing questions, giving specific directions, providing explanations, and tailoring the tasks toward finding key words. She tailors the tasks so her students can identify key words to determine which operation is needed, although the same keywords can lead to different operations. She deliberately does this to minimize students' confusion about whether to multiply or divide. However, while giving these specific directions and examples repeatedly, she limits time to discuss the meaning in the story problems (e.g., how to represent the story problems and how to use such representations to make sense of the problem situations and solve them) and the relationship between the two operations. As a result, after two days of using key words, most students were still confused about which operation was needed in which problem situation.

In contrast, the MTB teacher nurtures student learning overall, even though she tries to control and tailor student exploration at times in a way that constrains OTL. She frequently poses questions to invite student thinking and encourage students to consider various concepts and ideas related to the task. Such questions could be funneling and yet she manages to keep them open so that students can remind themselves of previous learning, connect that to the new task they are about to start, and think about approaches to the task. She deliberately suggests the base-ten chart and demonstrates how it can be used, and yet lets students decide whether to use it and how to use it. When trying to give clear directions, the teacher uses student thinking and has students come up with ideas along the way, rather than simply directing them to follow a set of procedures. Also, she adds a component at the end of the E-task that helps students reflect on the overall process. The lesson containing the W-task requires more than one session. The teacher's guide does not indicate where the task could potentially be suspended, let alone how to do so. The teacher decides to have students talk about what they learned and reflect back on their work on the task through this added component. Overall, she guides students in a very specific and organized way to engage students with the mathematics of the task.

Significance

It is surprising that there are still a number of decisions teachers have to make, even enacting W-tasks that include detailed guidance for the enactment (e.g., MTB). These decisions influence learning opportunities for student to experience. The results of this study can be used in teacher

preparation and professional development to help teachers make such design decisions in a way that can nurture student learning. The results can also be used to provide support for teachers to help them make better decisions. For example, the lessons on multiplication and division in INV can address how to guide students about key words and operations in a clearer way than the current edition (e.g., questions to ask, prompts to give, and directions for the task).

EVALUATING THE IMPACT OF COMPUTER-BASED AND TRADITIONAL LEARNING ENVIRONMENTS ON STUDENTS' KNOWLEDGE OF ALGEBRA

Erin Krupa

webelcm@missouri.edu

Jason McManus
Montclair State University
mcmanusj3@mail.montclair.edu

We share results from a quasi-experimental study in which we compared achievement between traditional lecture-based and computer-based sections of college algebra on a common multiple choice exam as well as performance on problem solving items. Students in the computer-based group performed better on the final exam and were also more likely to complete the problem solving tasks correctly than students in the traditional courses. However, the computer-based group showed limited ability to interpret an equation and relate it to a contextual situation.

Keywords: Curriculum, Technology, Post-secondary, Algebra & Algebraic Thinking

The use of "emporium" style delivery formats for basic college mathematics courses is spreading in the United States (Twigg, 2011). These courses are held in large computer labs, where the majority of instruction is provided through interaction with a computer program. The software provides examples, explanations, videos, opportunities to practice, and varying degrees of feedback on incorrect solutions. Emporium courses also employ trained instructional assistants who provide one-on-one "just in time" help (Hodges & Brill, 2007). The limited number of empirical studies conducted in these sites indicate positive effects on attendance, pass rates, performance on end-of-course exams, and future enrollment in math courses (Taylor, 2008; Twigg, 2011). Despite theses findings, it is unclear what mathematical knowledge students gain from learning in computer-based environments.

Objectives

The purpose of this paper is to report quantitative findings from a comparative study regarding the impact of computer-based versus face-to-face instruction for college algebra and to analyze students' solution strategies on non-routine mathematics tasks. This research is an important first step towards determining the extent to which these two contrasting learning environments influence mathematical knowledge and the degree to which students in these different environments are able to solve non-routine tasks in mathematics.

According to Twigg (2011), the success of the mathematics emporium model can be attributed to several characteristics, including: (a) students do problems rather than watching a lecturer do the problems, (b) students spend more time on what they do not understand and less time on what they already know, (c) students get timely assistance from the software as well as trained instructional assistants, and (d) students must master a requisite skill before they proceed to a more advanced skill. The characteristics listed above correspond to the broad finding that developing procedural skill requires teaching that incorporates modeling the skill followed by a significant amount of error-free practice on the part of the learner (Hiebert & Grouws, 2007).

At some universities, blended instruction incorporates some of these characteristics without removing the face-to-face lectures, still producing significant learning gains, and in some cases, improved self-efficacy beliefs for students (Hagerty & Smith, 2005; Hagerty, Smith, & Goodwin 2010; Kendricks, 2011; Taylor, 2008). Kodippilli and Senaratne (2008), found that passing rates

were 43% higher in a class that used MyMathLab, a software commonly used in mathematics emporia, than in a class where it was not used.

Despite this reported success, the emporium model raises concerns about the potential lack of attention to conceptual understanding. Erlwanger's (1973) classic description of the elementary student "Benny" serves as a reminder and warning about the kinds of misconceptions that can result from an individualized program that emphasizes correct answers and procedures without attending to students' understanding of mathematical concepts. This study attends to this concern by providing students an opportunity to apply their mathematical knowledge to problems that may seem non-routine and to explain how they think about the mathematical ideas and skills they use to solve the problems.

Methods

Context and Sample

In the Spring of 2012 the mathematics department at a mid-sized suburban university offered twelve sections of Intermediate Algebra. Six sections were held in a computer-based (CB), emporium-style environment and six sections were taught in traditional face-to-face (F2F) classes by adjunct professors who typically teach the course. The students did not know at the time of enrollment whether they would be assigned to the CB or F2F learning environment.

A quasi-experimental matched group design was used to explore the impact of the two settings on student learning, followed by finer grained analyses. As such, the sample includes three levels of participants, determined by data access granted by participants. Level 1 includes all students enrolled in Intermediate Algebra during the Spring of 2012 with an exam score (n_{CB}=134, n_{F2F}=192), Level 2 is made up of a subset of students from each learning environment (n_{CB}=73, n_{F2F}=50) and includes additional student-level predictors, and Level 3 participants are a subset of the Level 2 participants with completed non-routine tasks (n_{CB}=38, n_{F2F}=24).

Data Sources and Analysis

Each student took a common multiple-choice final exam at the conclusion of the semester through their normal means: CB via their computer program and F2F in their classroom. For the Level 1 analysis, a t-test was used to determine if there was a difference in the group means between the CB and F2F sections. To control for initial differences in the two student samples, as well as to explore the factors that influenced student achievement on the final exam between the two treatments, the Level 2 analysis included ANCOVA's with student-level variables for SAT math (prior achievement measure), high school GPA and Algebra II grade, and university GPA.

To determine if there were differences between CB and F2F in how students solved the problem-solving tasks, the Level 3 data include student responses on four problem-solving items. These items were given near the end of the semester for a small amount of extra-credit. They were completed individually, in class, on paper, and were based on major themes of the Intermediate Algebra course: systems of equations and quadratic functions. They were designed to represent various degrees of transfer from the kinds of procedural tasks they solved on the final exam. In this paper, we report on two problems, shown below:

1. Cindy bought 3 burgers and 2 soft drinks for $10.50. At the same restaurant, Sean bought 4 burgers and 3 soft drinks for $14.50. How much does 1 burger cost?
2. For a concert, the income from ticket sales is estimated to depend on ticket price according to the following equation: $t(x) = -25x^2 + 750x$, where x is price per ticket.
    a. Will increasing the price of the ticket always result in greater income? Explain how you know.

b. Find the ticket price where the concert will make the maximum amount of money, according to the equation. (Hirsch, Fey, Hart, Schoen, & Watkins, 2008)

Two members of the research team coded the students' solution strategies and whether the students answered the problem correctly. The two coders reached a 96% agreement on correct versus incorrect and 87% on the strategies the students used.

Level 1: All Students

On average, student achievement on the final exam was higher for students in the CB (μ=70.75, σ=15.29) than for students in the F2F sections (μ=65.49, σ=13.12). This difference was significant (t=-3.33, p" .001), which represented a small effect size (r=.182) (Cohen, 1988).

Level 2: Subset of Students with Additional Predictors

For the students participating in the Level 2 study, there was no significant difference between students enrolled in the F2F section (μ=68.59, σ=12.80) and those in the CB sections (μ=70.60, σ=16.01) (t=-0.74, p=.461). The ANCOVA, using SAT math as a covariate, showed a larger effect size, SAT math score significantly predicted students' final exam score (F=43.93, p<.0001). More interesting, when controlling for SAT math, the effect of the mode of delivery favored CB (F=3.58, p=.06). Furthermore, when the mode of delivery, SAT math, and the interaction between mode of delivery and SAT math were included as predictors, Mode was significantly related to final exam score (F=4.32, p=.040). In addition, Mode*SAT math was a significant predictor of student achievement (F= -2.31, p=.029). These findings suggest that there is a significant relationship between SAT math, the mode of delivery, and the final exam, such that, on average, students with higher SAT scores tended to perform better in the CB setting. Conversely, students with lower SAT scores tended to perform better in the F2F setting.

Level 3: Problem-Solving Tasks

On Task 1, 76% of the CB students answered the problem correctly, whereas only 58% of the F2F students responded with a correct answer. Students used strategies such as guess and check, elimination, or other algebraic strategies. Interestingly, students used different strategies depending on their learning environment (**Table 1**). Students in the F2F classes were more likely to guess and check and less likely to use an elimination strategy than those in the CB classes. These results show that although the CB students were more successful in solving the task, there was less variance in their strategies, whereas F2F students used a greater variety of strategies.

Table 1: Task 1 F2F and CB Percentage of Students' Solution Strategy

	Guess	Elimination	Algebraic	Other
Face-to-Face	46%	21%	16%	16%
Computer Based	27%	60%	12%	0%

The first part of Task 2 asked if increasing the ticket prices would always result in increased income. Of the F2F students, 78% correctly indicated that income would not continue to increase, justifying this conclusion by appealing to the problem context, the negative coefficient in the equation, or by testing values. In comparison, only 58% of the CB students correctly indicated that the income would not continue to increase. All of the F2F students gave a justification for their conclusion, but 18% of the CB students did not give any justification. For the second part, where students had to find the ticket price that would maximize income, only 31% of the F2F students found the correct ticket price, whereas 63% of the CB students found that a ticket price of $15 would maximize income. Students used many different strategies to

answer the second part of the problem (**Table 2**). All 37% of the CB students using the vertex equation obtained the correct answer, and, of the 32% of CB students who solved the problem by testing different values for the ticket price, all but two of them (83%) got the right answer. In contrast, none of the F2F students used the vertex equation and less than half of them found the correct answer by testing ticket prices. This problem reveals that while the CB students were more likely to use an algebraic procedure and to solve the problem correctly, they were less likely to recognize that the income would not continue to rise as the ticket price increased.

Table 2: Task 2 F2F and CB Percentage of Students' Solution Strategy

	Ver tex	Tests Value	Complete Sq./ Factor/Graph	Blank or No	Attempts to
Face-to-Face	0	61%	8	2	4
Computer	3	32%	1	2	0

Significance

As universities across the nation transition to more cost effective means of delivering mathematics instruction, it is important to verify that these methods of delivery are effective, not only in promoting students' procedural fluency but also in providing students with a rich experience that shows them the connections behind algorithmic procedures. This study suggests that while students in emporium-style settings may gain procedural fluency, they may be limited in their ability to interpret mathematical objects and relate them to contextual situations. Given the limited number of empirical studies on the impact of emporium-style math courses, more work is needed to explore not only systemic effects but also the nature of the mathematical knowledge that students gain in these settings.

AN ANALYSIS OF ALGEBRA CONTENT IN THE FINLAND AND TAIWAN ELEMENTARY SCHOOL MATHEMATICS TEXTBOOKS

Jane-Jane Lo
Western Michigan University

Der-Ching Yang & Wen-Chi Weng
National Chiayi University
dcyang@mail.ncyu.edu.tw

The major purpose of this study was to examine the similarities and differences in the contents of algebra topic in selected elementary school mathematics textbooks of Finland and Taiwan. The mathematics curriculum market leaders of Finland and Taiwan, Laskutaito and Kang Hsuan, were examined using content analysis method. Results show that while both textbook series introduce the early algebra through arithmetic and numerical reasoning, they differ from each other in terms of the use of patterning tasks. Furthermore, there is a significant difference in the representation forms of problems used in these textbooks and the use of contextual problems. Implications related to mathematics textbooks' design and teaching are discussed along with suggestions for future studies.

Keywords: curriculum analysis, algebra and algebraic thinking, elementary school education

Textbooks play a significant role in mathematics classrooms worldwide (Schmidt, McKnight, Valverde, Houang, & Wiley, 1997). They are commonly considered as a source of explanation and exercises for students to learn and for teachers to teach (Reys & Reys, 2006), and an important indicator for the opportunities to learn mathematics (Stein, Remillard, & Smith, 2007). The primary purpose of this study was to examine the similarities and differences in the contents of algebra topic in selected elementary school mathematics textbooks of Finland and Taiwan.

This study is significant in terms of the choice of the target countries, topic focus, and grade levels. Students in Finland and Taiwan are high achievers in PISA 2006 and 2009 (Organisation for Economic Co-operation and Development [OECD], 2010). It is important to find out what opportunities to learn are afforded to the students in these two countries. Furthermore, there is a growing recognition of the important role early algebra learning plays in the overall success with algebra (Common Core State Standards Initiative, 2010). A detailed analysis of the algebra materials in elementary mathematics textbooks from Taiwan and Finland will shed light on the content and characteristics of the mathematics problems used to support the development of early algebra reasoning in these two countries.

Prior Studies on Textbook Analysis

Prior studies on textbook analysis have focused on two primary issues. The first one is the content coverage. This includes learning goals, list of topics, meanings and representations of key concepts, sequence, pacing, and learning trajectories (Charalambous, Delaney, Hsu, & Mesa, 2010; Yang, Reys, & Wu, 2010). The second focus is classifying the textbook exercises and problems by various kinds of constructs and schemes. For example, Charalambous, Delaney, Hsu, and Mesa (2010) examined the fraction constructs (e.g., part-whole, measure, ratio, operator, quotient) used in elementary mathematics textbooks from Cyprus, Ireland, and Taiwan.

Early Algebra Learning

Carraher and Schliemann (2007) identified three entry points for early algebra learning. The first one is through arithmetic and numerical reasoning that includes the field of axioms, such as

commutative, associative properties that result from performing arithmetic operations. The second entry point is arithmetic and quantitative reasoning. The most prominent approach to early algebra learning based on quantitative reasoning is centered on the work developed by Davydov and his colleagues from the Vygotskian perspective (Schmittau, 2005). The third entry point is based on arithmetic and function (Carraher, Martinez, & Schliemann, 2008). Students are introduced to the numerical and geometrical patterns and are asked to predict the next one in informal language. Textbooks in certain parts of the world introduce formal algebraic notation and simple symbolic manipulations in the upper elementary grades. For example, Wong (2005) reported that students in Hong Kong are expected to solve simple equations involving fractions and decimals such as $x - 2.2 = 1.8$ or $y \times 2/3 = 4$ in sixth grade.

Based on the work summarized above, the following two research questions guide the design and analysis of this study:

1. What are the similarities and differences in the types of problems used in the selected textbook series in Finland and Taiwan in terms of content-dependent characteristics such content coverage, sequencing, pacing, and the emphasis in terms of arithmetic, quantitative, functional, or symbolic reasoning?
2. What are the similarities and differences in the types of problems used in these two selected textbook series in terms of content-independent characteristics?

Because of the space limitation, only selected findings will be discussed.

Method

Compulsory education in both Finland and Taiwan shares similar basic structures. Both are 9 years in length; during the first 6 years, a homeroom teacher is in charge of most subjects, while the subject specialists teach different subjects during the last 3 years of schooling. Also, they both have national curriculum guides (Ministry of Education in Finland, 2008; Ministry of Education in Taiwan, 2003).

The selected mathematics textbooks, Laskutaito (Saarelainen, 2006) and Kang Hsuan (KH, Kang Hsuan Educational Publishing Group, 2010), both have the highest market share in Finland and Taiwan, respectively. Both series have one booklet for each semester; thus, there are 12 booklets in each.

This study applied the content analysis method to analyze and code the problems presented in the mathematics textbooks (Yang et al., 2010). The data analysis of this study involved several stages. First, we went through all the problems in the mathematics textbooks and coded each one as to whether it was an algebra problem. The problems include the worked example (solutions were provided) and exercise problems following the worked examples (no solutions were provided) in the student textbooks. Two of the authors did all the coding and compared their results. The reliability was calculated using (shared algebra problems)/(total identified algebra problems) for each textbook (Ding & Li, 2010). The reliability for coding the Finland textbooks was 92%. The reliability for coding the Taiwan textbooks was 95%. The discrepancies between the coders were discussed to reach agreement before data analysis.

Second, we went through all the algebra problems in both textbook series and noted the main characteristics of these problems, in terms of both the content-independent and dependent ones. To confirm our observations, we coded all the algebra problems along these two sets of characteristics. To check the reliability for each of the aforementioned categories of the algebra problems (context vs. non-context, and different forms), all of the algebra problems were randomly selected and coded independently by the first and second authors for each textbook. Both coders discussed any discrepancies among the problems to reach agreement for the final

results. Finally, several themes emerged during these iterations of analyses when comparing similar problems from both textbook series, which will be discussed in the next section.

Selected Findings

The primary focus of the algebra problems in the Finland elementary textbook starts with developing arithmetic and numerical reasoning, and pattern recognition ability. As each operation is introduced, students first learn to write and evaluate expressions for given contextual problems, then solve number sentence problems with the unknown represented with "$\square$," and finally with the letters "x" and "y" in sixth grade. Properties of operations such as commutative laws and order of operations are introduced with concrete examples and plenty of exercises to consolidate the ideas. The design of the Finland elementary math textbook is spiral. Old ideas are revisited briefly before they are used with larger whole numbers or rational numbers with more complex computations. In addition, logical patterning tasks are first introduced at the first grade level and revisited with increased complexity throughout the remainder of the five grades.

Similar to algebra problems in the Finland curriculum, Taiwan textbooks encourage students to learn how to write the expression with the unknown represented with "( )" for given contextual problems, and to learn how to solve them with various algebraic properties first, and then with "x" and "y" in grade six. However, the algebra problems in the Taiwan elementary textbook do not focus on patterning recognition tasks as much as the Finland textbook in the early grades. The Kang Hsuan series does contain exercises that encourage students to find the regularity in the expression for the total number of chairs when the number of tables is "n." This kind of numerical patterning task is not found in the Laskutaito series.

There are a few other marked differences. KH tends to focus on a single unknown quantity, while Laskutaito includes ample exercises that require students to reason with multiple quantities. KH includes far more worked-out examples than Laskutaito. In addition to showing step-by-step instructions, KH provides examples and subquestions that guide students through the reasoning process. For example, KH asks students the following series of questions: "A fruit basket weighs 50 g. How much would it weigh all together after putting in fruit that weighs 100 g, 200 g, 300 g, x g?" After students have plenty of experience in writing expressions with a single operation, they then are given problems that involve multiple operations, for example, "Ji-Hua and three friends went on a picnic. They spent 160 NT dollars to buy bus tickets and x NT dollars to buy snacks. Write an expression to show the amount of money each person should pay. If x = NT 120 dollars, what is one person's share? If x = NT 200 dollars, what is one person's share?" Finally, the textbook illustrates the additive and multiplicative axioms and how they can be used to solve equations such as $y \div 0.8 - 8 = 12$ by first adding 8, and then multiplying by 0.8 to both sides of the equal sign.

Discussion and Implications

This research reports the results of an analysis of elementary mathematics textbooks that are used in Finland and Taiwan. Both textbook series introduce the early algebraic concepts to their students through arithmetic and numerical reasoning, with an emphasis on a conceptual understanding of various principles and properties for the four basic operations. In addition, Laskutaito provides logical patterning tasks throughout all grade levels, while KH includes discussion of numerical patterning tasks that prepares students for a functional approach. The problems in KH tend to focus on one unknown quantity, while Laskutaito provides students an opportunity to reason with multiple quantities. Finally, both textbooks include some worked-out

examples; the solutions in Laskutaito include only computation steps, while those in KH include the reasoning behind those steps.

This difference reflects the different types of algebraic reasoning afforded by each textbook series. The early and systematic approach of algebraic reasoning through arithmetic and numerical reasoning might have contributed to the good performance of Finnish and Taiwanese students in the international assessment. How and to what extent students' algebraic reasoning is influenced by the different curricular emphasis is a topic worthy of future study. For example, will middle school students in Taiwan perform better on the numerical patterning tasks because of their experience with such tasks in the elementary grades? With less explicit reasoning and more variety of representations included in the algebraic problems, teachers and students in Finland are freer to explore and to make connections between concrete and abstract ideas through logical and pattern reasoning than their Taiwanese counterparts. However, such differences in the textbooks' approach may increase the importance of the teacher's knowledge and experience in facilitating students' learning through the given curriculum (Stein et al., 2007). This could potentially lead to more variation in terms of curriculum implementation. Future studies can be conducted to test this conjecture.

ANALYZING TEACHER INSTRUCTIONAL MOVES AROUND HIGH-LEVEL TASKS: IMPLICATIONS FOR CURRICULUM DESIGN

Amanda Fisher
University of Illinois at Chicago
afishe8@uic.edu

Alison Castro Superfine
University of Illinois at Chicago
amcastro@uic.edu

Despite the growing research on how teacher instructional moves support or inhibit students in engaging with a task at a high level of cognitive demand, it is unclear how to design teacher materials in ways that support teachers in making instructional moves that bolster student task engagement at a high level. This case study presents an analysis of one teacher's instructional moves as she used the Intensified Algebra curriculum in a double period high school algebra classroom. By analyzing the transcripts of several lesson enactments, we found that this teacher's debrief episodes tend to start out with high-level communication moves but shift into low-level moves by the end of the episode or debrief period. This finding suggests that the teacher materials should be revised to include more information about how to engage in high level communication moves during debrief segments.

Keywords: Curriculum, Instructional Activities and Practices, High School Education

Reform efforts in mathematics education have ushered in changes in the ways that mathematics is taught and learned in classrooms. While students are expected to communicate mathematically about their ideas, discuss and make conjectures, teachers, in turn, are expected to facilitate these discussions among students and ask questions in ways that further students' thinking (NCTM, 2000). Yet, research has consistently demonstrated that teachers' instructional moves can either support or inhibit students' work on a task at a high level of cognitive demand (Boston, 2012; Henningsen & Stein, 1997). Indeed, facilitating students' communication about mathematical ideas and concepts around high-level tasks can be instructionally challenging for teachers as the nature of student thinking is often unpredictable (Henningsen & Stein, 1997). What is less clear are the ways in which mathematics curriculum materials support teachers in maintaining students' work on tasks at a high level during instruction. In this study, we analyze the instructional moves of a teacher using the *Intensified Algebra* (IA) curriculum, a year-long program designed for use in double-period high school algebra classes. In doing so, our aim is to gain insight into ways that teacher materials (e.g., teacher guides) can be designed to support teachers as they facilitate students' communication around and work on tasks at a high level of cognitive demand.

Background

Curriculum materials are a primary tool – a curriculum development artifact that mediates teachers' actions and helps them to accomplish curricular goals - for teachers as they implement a given curriculum program (Brown, 2009). Thus, we assume both teachers and the curriculum materials, including the teacher support materials, interact with and influence each other. Under this view of teacher-curriculum interactions, teachers may either closely adhere to the suggestions in the curriculum materials or choose to make modifications based on various factors in their particular classroom environment, such as students' needs and abilities, experience and familiarity with the curriculum program, and their own beliefs about learning (Brown, 2009). These decisions and the actions that follow may be generally called instructional moves. Given

that teacher materials are generally designed to support teachers in implementing the curriculum and supporting students' work as part of the curriculum, we are particularly interested in the ways in which teachers' instructional moves support students' communication around high-level tasks, and the nature of the instructional support provided in the teacher materials for supporting students' communication at a high-level.

Method

As part of the larger research project around the IA curriculum, six teachers were videotaped and observed across at least 10 lessons over the course of the 2010-2011 school year. All videotaped lessons were transcribed. For the purposes of our current study, we include our analysis of only one of these teachers, Laura. All names are pseudonyms. She was selected as a case study because as we analyzed the videos from the larger project we saw evidence of her using the curriculum materials with a fairly high degree of fidelity during lesson enactments. Furthermore, in an interview with Laura, she indicated that she regularly used the teacher materials (i.e., Advice for Instruction (AFI)) while planning for instruction.

In the first phase of our analysis, we determined levels of cognitive demand that are placed on students as determined by the written task. Using the Stein and Smith (1998) math task framework, we identified whether the lesson contained a high- or low-level task. High level cognitive demand tasks require that students reason about the mathematics and explore multiple solution paths, thus making the instructional work for teachers unpredictable and often challenging (Henningsen & Stein, 1997). Thus, we chose to focus our analysis on those lessons containing high cognitive demand tasks. In the second phase of our analysis, we segmented each lesson transcript into interactional episodes based on the nature of the mathematical task. For example, in the launch portions of the lessons, a teacher may introduce a concept, connect to previous concepts, or introduce a particular task. The episodes allow for an analysis of teacher instructional moves as they relate to the AFI. We then annotated each episode with the information provided in the AFI. In other words, what was the nature of instructional support provided in the AFI for each episode. In the third phase of our analysis, we developed a list of teacher instructional moves that supported student thinking at a high level and those instructional moves that inhibited student thinking at a high level, based on a review of current research on teacher instructional moves, classroom communication, and mathematical tasks. Table 1 below is a list of the codes and their definitions. Due to space constraints, we only include a few codes.

Table 1: Teacher Instructional Moves

Surface-level Instructional Moves		High-level Instructional Moves	
Explicates steps	Teacher specifies explicit procedures <u>prior to investigation</u>, through either: (a) Direct explanation of the procedure or through the use of similar examples (b) Funneling or leading questions prior to investigation.	Elicits reasoning	Teacher asks students for justification of procedures
Takes over	(a) Teacher does part of the	Presses	Teacher presses students

	problem with the whole class, taking the challenge out of the problem (after students have already begun investigation) (b)Teacher finishes an explanation for a student.		for accuracy and clarity in their reasoning
Low accountability	(a) Unclear or incorrect explanations are accepted by Teacher (b) Teacher allows students to supply only procedure when justification is requested	Refers back	Teacher explicitly calls attention to and refers back to shared conclusions or assumptions from a different class session.

The instructional moves have been divided into two categories, surface-level moves and high-level moves, according to whether or not they support students' communication at a high level of cognitive demand or at a surface level. Though surface-level communication moves may not support engagement at a high-level of demand, we do not assume these moves are always negative or necessarily inappropriate. However, noting any patterns or shifts from surface to high-level moves, or high- to surface-level, along with noting to what extent Laura follows the AFI directions, allows us to identify features within the AFI that are less supportive of implementation at a high level of cognitive demand. In the fourth phase of our analysis, both authors independently coded each lesson, compared codes, and resolved any discrepancies through discussion. Once coded, we identified any patterns in the presence and absence of different codes, and compared the final codes with the information provided in the AFI.

Results

Our results suggest several emergent patterns in the data. First, episodes where Laura followed the AFI least—or, in other words, made the most the modifications—had mostly low-level communication moves. In fact, out of the ten episodes in which Laura made modifications, eight of them were coded for low-level communication moves. The type of instructional support in the AFI in these lessons includes some suggested questions to ask students, as well as anticipations of student thinking, however this type of information is not consistently given within or across lessons in the AFI. This suggests that the AFI may not support teachers in making modifications to suit their local conditions in ways that are reflective of the goals of the IA curriculum. However, this may be a professional development issue—how to modify lesson plans when students are confused—than one of redesigning teacher materials.

Second, the debrief episodes tend to start out with high-level moves, such as eliciting reasoning, but shift into low-level moves, such as taking over and holding students to low accountability in their responses, by the end of the episode or debrief period. This suggests that the debrief portions of the support materials may be missing the kind of information teachers need in order to maintain the use of instructional moves that facilitate student communication at a high-level even in the face of student confusion. Though there may be some general ideas to help teachers in this way, and therefore the purview of professional development, it is likely that specific support for a lesson is needed as well.

Finally, in the lessons analyzed, Laura did ask for justification of procedures (i.e., elicits reasoning) but did not ask for explanation of thinking (i.e., elicits explanation). This small but non-trivial distinction between reasoning about a specific procedure versus more general mathematical reasoning may not be clear in the teacher materials. Thus, as teachers modify questions or add in their own, they may not recognize the need for both types of questions, and as such, the materials may need to be revised to address this distinction.

Implications for IA Curriculum Design

Our results suggest important implications for the design of the IA curriculum program. First, many of Laura's low-level moves we identified were examples of holding students accountable for low-level products, such as incorrect responses, one-word or numerical responses when the AFI called for more robust explanations from students. Thus, one implication for the design of the AFI around these lessons is to provide suggestions as to how to support pressing students for clarity. This could take the form of sample student responses for particularly difficult questions. Second, we identified several instances of Laura taking over the thinking around the task. Thus, one implication for the design of the AFI is to include ways to remind teachers not to take over the thinking. This could take the form of placing reminders at key points in which teachers tend to take over. Third, many of Laura's low-level moves also included taking over explanations or the more challenging parts of tasks. Thus, another implication for the design of the AFI is to include ways to support teachers in encouraging students to comment on or argue about other students' ideas. Finally, we identified relatively few instances of Laura linking concepts and strategies used while solving tasks. Thus, another implication for the design of the AFI is to include ways to support teachers in making such links, particularly for lessons with multiple solution paths. This could take the form of diagrams or other representations of multiple solution paths and their links as a means of reminding teachers of the importance of highlighting those links with their students.

To be sure, teachers implement the curriculum through a filter of their conceptions of, and orientations toward, what it means to learn and teach mathematics. Nevertheless, the information gleaned from this analysis can help curriculum developers revisit and refine what is in the IA curriculum materials, specifically the AFI, and determine better ways to facilitate more effective implementation.

THE ASSOCIATIONS BETWEEN READABILITY MEASURES AND PROBLEM SOLVING IN ALGEBRA

Solving mathematics story problems requires text comprehension skills. However, previous studies have found few connections between traditional measures of readability and performance on story problems. We hypothesized that recently-developed measures of readability may illuminate associations between text difficulty and problem solving. We used data from 3,394 middle and high school students solving algebra story problems in Cognitive Tutor Algebra. We found that several indicators of readability were negatively associated with incorrect answers. Moreover, indicators of readability were associated with students requesting hints from Cognitive Tutor. These findings are discussed in the context of models of algebra problem solving and previous research on text difficulty in solving story problems.

Keywords: Curriculum, Cognition, Problem Solving

Theoretical Framework

Algebra word problems, or story problems, can provide access to important mathematical concepts. Their concrete, verbal language can connect to students' prior experiences, providing a conceptual foundation on which more advanced skills can be built (Koedinger & Nathan, 2004; Walkington, Sherman, & Petrosino, 2012). However, in order to understand and solve story problems, students must be able to comprehend and interpret the story text (Kintsch & Greeno, 1985). This idea is articulated in Nathan, Kintsch, and Young's (1992) framework for algebra story problem solving, where students develop a mental representation of the actions and relationships in a story problem's text, a *situation model*, as well as a mental representation of the formal mathematics, a *problem model*. The coordination of situation and problem models is a key element of learning from algebra story problems (Walkington et al., 2012).

Based on this framework, it is reasonable to assume that the readability of story problems contributes to their difficulty. However, researchers have found minimal evidence linking the readability with problem solving accuracy (Wiest, 2003). One reason may be the use of traditional measures of readability that assess the text based on the familiarity of the words, the number of syllables, and the number of words per sentence (Graesser, McNamara, & Louwerse, 2012). These measures provide coarse estimates of a text's difficulty, but do not, for instance, capture the *cohesion* of text – the "linguistic glue" that joins the events and ideas, helping readers to understand connections and relationships (Gernsbacher, 1997; McNamara, Graesser, McCarthy, & Cai, in press). For example, the use of consistent verb tense (e.g., past or present) in different sentences can cue the reader that the actions in these sentences occurred during the same time period. Research in elementary mathematics has also suggested that story problems with clear and explicit action (e.g., joining, separating) facilitate problem solving (Carpenter et al., 1999). Given Nathan et al.'s (1992) framework, measures relating to cohesion and explicit action may be a critical component of solving story problems.

In the present study, we examine the texts of a large set of algebra story problems solved by students in a variety of school settings. We argue that some types of story texts may better facilitate the construction of meaningful situation models and their coordination with problem models. We have two research questions: (1) How are different measures of text readability associated with students' accuracy when solving algebra story problems? and (2) How are different measures of text readability associated with students' help-seeking when solving algebra story problems? By investigating these questions, we seek to better understand the previously unclear relationship between text difficulty and solving story problems.

Method

Cognitive Tutor Algebra (CTA) is a computer-based intelligent tutoring system for Algebra I in use in schools across the United States. The tutoring system presents students with algebra problems and provides adaptive hints if the student requests them (Morgan & Ritter, 2002). As students work through the program, detailed log files are created that store students' interactions with the system. We used the CTA log files from 9 high schools and 1 middle school containing $N = 3394$ students with active CTA accounts. These schools were in 10 different states, with 2 rural, 4 urban, and 4 suburban schools. Three schools had 0-33% of students eligible for free/reduced lunch, four had 33-66% eligible, two had 66-100% eligible, and one did not have this information available. Five schools had student populations that were predominately White students, three were predominantly African-American students, and two were predominately Hispanic students. Schools also varied in achievement on standardized mathematics assessments.

Data were collected from the first 8 units in CTA that used story problems with linear functions; CTA is adaptive to student needs, so not all students receive all problems. After demo problems, problems with missing data, and problems with data from fewer than 15 students were omitted, 282 problems remained. On average, each problem had been solved by 398 students ($SD = 321$). Each story problem had several parts and required students to write a symbolic expression stating the linear relationship(s) in the story and fill out a table; some problems also had students construct graphs. See carnegie.learning.com for examples of problems.

In the present study, students' average error rate on each problem and their rate of asking the system for a hint were compiled from the CTA log files. Then the text of the introduction to the story problem was entered into the Coh-Metrix 3.0 software. The introduction can be one or more sentences, and generally describes the slope and intercept terms of the story (see Table 2). Coh-Metrix is a software tool developed in 2002 that provides multiple, varied, and precise measures of readability (e.g., frequency of different types of words like pronouns and verbs), measures of cohesion (e.g., degree of narrative language or time-related cues), in addition to traditional measures of readability (e.g., number of sentences or word syllables; McNamara et al., in press). Coh-Metrix measures were entered into regression models to test if they significantly predicted the percentage of attempts on that problem that were incorrect, or the percentage of attempts in which hints were requested. The regression models controlled for aspects of the story's mathematical structure, including the structure of the linear function(s) (e.g., positive slope/no intercept, negative slope/negative intercept), the type of numbers used (e.g., fractions, large whole numbers), and the unit and section the story problem came from.

Results and Discussion

Accuracy

Table 1 shows only the readability measures from Coh-Metrix that significantly predicted students giving inaccurate responses: Text Easability PC Temporality, and incidence of adverbs, intentional verbs and third person singular pronouns. For the scale on which each of these values was measured by Coh-Metrix (to interpret the B values), see http://cohmetrix.memphis.edu. "Text Easability PC Temporality" measures how many cues about temporality the text contains, and how consistent tense (e.g., present or past) and aspect (perfect or imperfect) are. This captures how well sequences of events that occur in the past, present, or future are made explicit, including cues like "an hour later." Consistent verb tense provides coherence that helps the student connect the information in different sentences (Gernsbacher, 1996). Thus it is not surprising that Table 1 shows that as temporal cohesion increases, incorrect answers decrease (indicated by the negative B value). Related to this is the result in Table 1 that as incidence of adverbs increase, incorrect answers decrease. Adverbs can provide temporal cues, which may help the reader follow the time course of the story. Adverbs can also add descriptive information about how and to what extent actions and events occurred. This information may enrich the story context, providing cues that support situation model construction. Examples of problems with both high and low scores on these measures can be seen below in Table 2.

Table 1: Regression Results for the Impact of Readability on Problem Solving Accuracy

	B	SE(B)	*T*	*p*
(Intercept)	21.153	2.096	10.094	0.0001
Text Easability PC Temporality	-0.030	0.008	-4.042	0.0002
Adverb incidence	-0.045	0.011	-4.176	0.0004
Intentional verbs incidence	-0.026	0.011	-2.290	0.0154
Third person singular pronoun incidence	-0.024	0.011	-2.182	0.0284

Table 2: Sample Problems for Comparison of Readability Scores in Two Measures

Measure	High	Low
Text Easability PC Temporality	We ***work*** for a company that ***makes*** and ***sells*** hot-air balloons. Each hot-air balloon ***sells*** for $3500. Our warehouse ***has*** 20 balloons that ***have already been*** sold but ***have not yet been*** shipped. (Coh-Metrix 98.26 percentile)	We ***are building*** doghouses and ***have already finished*** five of them. A local store ***agrees to buy*** as many as we ***can make*** for $25 apiece. (Coh-Metrix 0.03 percentile)
Adverb Incidence	Many people do not realize that when one issues a false fire alarm the community ***needlessly*** spends thousands of dollars to protect the citizens. The money that gets wasted and ***eventually*** translates into higher taxes for everyone is approximately $4000 per call. This includes the costs to maintain the trucks and equipment the ***very*** expensive insurance and the salaries of the firefighters and other employees. This financial loss to the community is the reason why the fines for ***such*** illegal activity are ***so*** high. (Coh-Metrix score 107.143).	A friend offers us a job selling snow cones. Since he owns the snow cone maker he will let us use it for $50. We will make $0.50 on each snow cone we sell. (Coh-Metrix score 0)

Table 1 also shows that as intentional verbs and third person pronouns in a story problem increase, incorrect answers decrease. Story problems are easier for students to solve when there are purpose-driven, goal-oriented actions like buying a house or cooking a meal. The concrete information provided by intentional verbs may assist the student in developing a more vivid and meaningful situation model. Pronouns also act as facilitators when they have clear referents in the story text (White, 2012). Pronouns provide cues that prompt the student to connect the new information containing the pronoun with the old information containing the referent.

Help-Seeking

Table 3 shows the readability measures from Coh-Metrix that significantly predicted students requesting a hint from Cognitive Tutor. Story problems that had more sentences in them were more likely to promote students asking for hints, rather than attempting the problem; a long story text may be discouraging and increase perceived difficulty (White, 2012). Temporal connectives like "first" and "then" were associated with more hint-seeking, which is unexpected given other temporal coherence cues were negatively associated with inaccurate answers. Students who see a text with multiple temporal cues may be intimidated by the amount of information to process. These students may seek a hint even though the temporal connectives improve situation model construction. Finally, we see that stories with third person singular pronouns are associated with less hint-seeking, which is consistent with the problem-solving accuracy findings.

Table 3: Regression results for the impact of readability on hint requests

	B	SE(B)	*t*	*p*
(Intercept)	2.398	0.868	2.762	0.0018
Sentence count, number of sentences	0.343	0.099	3.470	0.0004
Temporal connectives incidence	0.013	0.005	2.843	0.0042
Third person singular pronoun incidence	-0.014	0.004	-3.282	0.0012

Significance

The purpose of this study was to examine associations between readability measures and solving algebra story problems, using recent advances in software-based text mining. Our results suggest important implications for mathematics teaching and curriculum design. Formulating problems in which the student is cued to connect related events appears to facilitate problem-solving. Avoiding overly lengthy story contexts and overuse of temporal cues may also provide initial access. Future studies could vary the readability levels of problems on these indicators, and examine student learning. These results are different from previous findings on this topic in which traditional, coarse measures of readability have been used. According to the model we presented for algebra story problem-solving (Nathan et al., 1992), our findings suggest that students were better able to solve a story problem if its text supported their construction of a situation model and its coordination with their problem model.

CROSS-COUNTRY BORDERLAND STUDY OF HIGH SCHOOL MATHEMATICS CURRICULUM IN MEXICO AND USA

Rocio E. Gallardo
University of Texas
regallardo@miners.utep.edu

Mourat Tchoshanov
University of Texas
mouratt@utep.edu

The aim of this comparative study is to examine similarities and differences between Mexico and Texas borderland high school mathematics curriculum. In Mexico, Secretaria de Educación Publica (SEP) is responsible to develop the content, curriculum and schedules at all educational levels. According to the SEP (2012), the mathematics programs contain teachers' goal, blocks distribution, generic skills, and basic competences for disciplinary field. SEP (2012) established that main teachers' goal is to "design meaningful activities that allow students to link previous knowledge with learning objects" (p. 6). The blocks include mathematics topics. Generic skills are students' abilities to understand their environment (local, regional, national or international). Basic mathematics competences include the following: construct and interpret mathematical models; formulate and solve mathematical problems; interpret the results obtained by mathematical procedures and contrast with established models or real situations. On the other side of the borderland, the Texas Education Agency established Texas Essential Knowledge and Skills (TEKS) standards to design high school mathematics curriculum. The TEKS for each high school mathematics course includes basic understandings as well as knowledge and skills, which are subdivided by mathematical process and content standards. According to TEKS (2012), "... the basic understandings of number, operation, and quantitative reasoning; patterns, relationships, and algebraic thinking; geometry; measurement; and probability and statistics are essential foundations for all work in high school mathematics" (p. 1).

The comparative study addresses the following research questions: *(1)* What are the main characteristics (e.g., standards, curriculum, scope and sequence) of high school mathematics curriculum in Mexico? *(2)* What are the main characteristics of high school mathematics curriculum in Texas? *(3)* To what extend high school mathematics curricular in borderland of Mexico and USA are similar and different? The conceptual framework for this study is grounded in the cross-cultural theory. Studies (e.g. Lui & Leung, 2013; Shimizu & Kaur, 2013) mention that understanding and analyzing the similarities and differences of the mathematics curriculum between two countries can facilitate mathematics teaching through cross-national studies. Similarly, this can help mathematics educators to analyze the different programs implemented by educational systems in two countries. The analysis is based on data (e.g., standards, curriculum) drawn from the SEP and TEA resources. The cross–country borderland curriculum analysis table was designed to determine and examine similarities and differences in the scope and sequence of the high school curriculum in Mexico and USA.

COMPARING STUDENTS' PERCEPTION OF MATHEMATICAL UNDERSTANDING AND STUDENT PERFORMANCE

Deena Soffer Goldstein
Univ. of Illinois at Chicago
dsoffe2@uic.edu

Louis V. DiBello
Univ. of Illinois at Chicago
ldibello@uic.edu

Catherine A. Kaduk
Univ. of Illinois at Chicago
ckaduk2@uic.edu

Students' self-perception of ability and understanding in mathematics influences confidence and self-efficacy, which, in turn, influences mathematics learning (Parajes and Miller, 1997; Kilpatrick, 2001; Mengelkamp, 2009; Kleitzman, 2013). Current research has found that educators and researchers underestimate the value of self-assessments as a socio-cognitive tool (Parajes & Miller, 1997). Other research has called for valid measures of self-assessment, not only to evaluate confidence, but also to validate the assessments (Kleitzmann, 2013). Little, if any research, however, evaluates the relationship between curricular self-assessments and student performance on the assessments. The current study evaluates the relationship between student self-reporting of mathematical understanding and performance in mathematics on the end-of-unit tests within the reform mathematics curricula, *Everyday Mathematics*, in order to assess: (1) how students' perceptions of their abilities for a specific curricular goal correlate to their actual performance on the end of unit test, (2) how self-perceptions and performance vary across students, classrooms, and schools, and (3) the validity of the curricular self-assessments, for particular learning goals.

The current study is a part of a larger project that addresses questions about cognitive, instructional, and inferential aspects of validity of assessments embedded in elementary mathematics curricula. Specifically, this study examines the accuracy and other visible features of student responses to evaluate the relationship between students' latent understanding and self-evaluations. Over one thousand samples of student work across three grade levels were scored and analyzed using an innovative scoring method, which includes scoring for accuracy as well as features of student answers that provide evidence of partial understanding.

Initial findings have shown that overall self-reporting of learning goals does not correlate with performance. However, when self-assessments were separated by learning goals, we found different patterns of self-reporting differed among learning goals. For instance, in a grade 4 unit test (n=195), self-assessments scores for *geometry* learning goals were equally distributed across all performance levels (*Figure 1*). However, *operations and computation* showed a stronger relationship between self-reported understanding and performance (*Figure 2*). Analyses across students and the educational implications will be discussed.

TEACHERS' OPPORTUNITY FOR LEARNING PEDAGOGICAL CONTENT KNOWLEDGE REGARDING INVERSE FUNCTIONS FROM HIGH SCHOOL MATHEMATICS TEXTBOOKS

Dana Grosser-Clarkson
University of Maryland
dgrosser@umd.edu

Keywords: Curriculum Analysis, Secondary Mathematics, Algebra and Algebraic Thinking

The release of the NCTM 1989 Curriculum Standards led to a shift in mathematics curricula (Remillard, 2005); instead of "speaking *through* teachers" some teacher guides were "speaking *to* teachers" (Remillard, 2000, p. 347). This prompted several studies examining the "extent to which curriculum materials could be designed to be educative for teachers" (Remillard, 2005, p. 231). This study is an exploratory analysis of teachers' opportunities for learning pedagogical content knowledge from current high school mathematics textbooks. Lessons regarding inverse functions were selected from five curricula for this analysis. Inverse functions were identified as the content focus, as this material is often problematic for secondary students (Wilson, Adamson, Cox, & O'Bryan, 2011). Moreover, Wilson and colleagues claim teachers unknowingly mislead students regarding inverse functions because they teach what is "in the textbook" (p. 501). This bold statement motivated a close examination of the information textbooks provide teachers regarding inverse functions.

Remillard (2005) defines *structures* as the "plans, activities, scripts, suggestions, information, explanations and messages" of the curriculum (p.234). This study examines these structures in lessons from the teacher's editions of five high school curricula: Interactive Mathematics Program, Core-Plus Mathematics Program, MATH Connections, Glencoe, and Prentice Hall. These were chosen as a representative sample of current high school curricula and include both integrated and strand-based sequences (i.e., Algebra, Geometry, and Algebra II).

The structures of each lesson were coded by identifying text that aligns with Shulman's (1986) concept of *pedagogical content knowledge*, a notion "which goes beyond knowledge of subject matter per se to the dimension of subject matter knowledge *for teaching*" (p. 9). Within Shulman's concept of PCK, six themes were identified and utilized to code the lessons. These themes are as follows: student pre-conceptions, student conceptions, student misconceptions, importance of multiple representations, use of powerful analogies, and the reorganization of student understanding.

This poster will display the findings from this study. For example, while most of the lessons examined noted possible student misconceptions regarding inverse notation, few of them contained powerful analogies, student pre-conceptions, or multiple representations.

Keywords: Measurement, Standards, Curriculum, Assessment and Evaluation

This study describes the ongoing development, scaling, and validation efforts of assessments of elementary and middle school students' understanding in engineering, science, and mathematics. Item response theory models are used to characterize the properties of each assessment and to generate estimates of student's proficiency. The work is part of a larger project focused on increasing student learning in grades 4 – 8 through an engineering design-based integrated approach to STEM instruction and assessment. The assessments fill an important gap in the literature by providing psychometrically sound tools to gauge students' understanding of engineering, science, and mathematics concepts for the specified grades.

A HISTORICAL EXAMINATION OF THE TREATMENT OF RATIO, RATE AND PROPORTION IN US MATHEMATICS TEXTBOOKS

Jia He
Michigan State University
hejia1@msu.edu

Keywords: Curriculum Analysis, Middle School Education

This poster is intended to examine, from a historical perspective, changes in the definitions of ratio, rate and proportion and the sequencing of these concepts in textbooks. Three research questions lead the investigation: (a) How are ratio, rate and proportion defined in textbooks? (b) How do textbooks derive properties (e.g., the property to reduce ratio to an equivalent ratio)? (c) What are the curricular sequences of developing proportion through either ratio, rate or other means?

My analysis of the textbooks examined three aspects: definitions, deduction of properties, and curricular sequences. Definitions are considered fundamental in mathematics and mathematics education (Zaslavsky and Shir, 2005) due to the multiple roles they play, for example as a foundation for proofs. As the community of mathematics educators calls for conceptual understanding (e.g, Kilpatrick, Swafford & Findell, 2001), the deduction of the properties and curricular sequences in approaching certain concepts are worthwhile to explore.

An analytical framework was built on both literature and data. Possible definitions of ratio include: (a) number/fraction/percent; (b) division; (c) ordered pairs. Definitions of rate include: (a) percent; (b) a comparison of two quantities with two different units. The definition of proportion is a statement of equality of two ratios. Each textbook was analyzed individually and patterns across the period were observed. Also, I analyzed each textbook's derivation of properties based on the consistency of the process with its given definition. I also examined the curricular sequence through each textbook's set-up of proportions: through either ratio, rate or other means including "per unit rate" and "building a rate table".

Nine elementary textbooks (grade 5 to 8) were selected for inspection based on two criteria: (a) the nine books were distributed relatively evenly from 1833 to 2004; (b) each book had rich content of ratio, rate and proportion. Each page with definitions of the three concepts and each whole chapter or section with a main topic of ratio, rate or proportion was selected for analysis.

Results indicate that the formal definitions of ratio and proportion stay stable across this period but the definition of rate switched from type (a) to (b) around 1960. Across this period, textbooks' explanations of reduction of ratio is consistent with the definition given. Textbooks since the 1990s tend to clarify multiple meanings of ratio without explaining how reduction of ratio works when the meaning shifts. From this perspective, recent textbooks seem less rigorous than older textbooks. Before the 1960s, ratio was the main method of setting up proportions but the explanation was strictly procedural. After the 1960s, rate became more central in setting up proportions within real world contexts.

CALCULUS TEXTBOOKS' TREATMENT OF THE CONCEPT OF LIMIT AND APOS THEORY

Dae S. Hong
University of Iowa
dae-hong@uiowa.edu

Keywords: Advanced Mathematical Thinking, Curriculum, Post-Secondary Education

Although the concept of limit is considered fundamental to the study of advanced mathematics, research suggests that students have limited views and misconceptions about the concept (Tall & Vinner, 1981). Some researchers suggest that students' informal knowledge and intuition can cause misconceptions while other researchers discovered that insufficient development of students' informal knowledge and intuition partially explain their difficulties (Cottrill et al., 1996). Attempts have been made to develop instructional methods to aid students to use the rigorous definition of limit properly (Cottrill et al. 1996). Swinyard and his colleague (2011, 2012) used genetic decomposition, proposed by Cottrill et al. (1996), to guide students through reinventing the formal definition of limit. Cottrill et al. (1996) called this process APOS (Actions, Processes, Objects, Schemas) theory. The results of Swinyard's studies are interesting because providing specialized instruction may be the key to overcoming students' difficulties and misconceptions by filling the gap between informal knowledge and formal mathematics (Gravemeijer & Doorman, 1999). One of the possible obstacles of limited views and misconceptions is knowledge proposed in textbooks (Barbe et al., 2005). This study will illustrate how two popular calculus textbooks, Stewarts and Thomas Calculus, treat the topic and whether exercise problems are designed in a way to use students' intuition and previous knowledge so that students can complete each stage of genetic decomposition and APOS theory.

INFLUENCE OF FOUNDATIONAL COURSES ON PERSISTENCE IN STEM

Tom L.W. Lougheed
Washington State University
lougheed@math.wsu.edu

Sandra C. Cooper
Washington State University
scooper@math.wsu.edu

As the world economy becomes increasingly technological, demand for degrees in Scientific, Technical, Engineering, and Mathematical (STEM) fields has grown both among employers and students. But for several decades U.S. students have been graduating with STEM degrees in about half the number desired by industry. Also, about half the students attempting a STEM degree persist to graduation, so any improvement in retention of STEM students will produce a nearly equal proportional reduction in the deficit of candidates reported by industry.

The research question addressed here is *Are student's decisions to leave STEM programs related to their successes or failures in their first college mathematics courses?*

In a study of engineering students, Gardner, et al. (2007) found that the single important factor that predicted graduation, among many considered, was students' grade in their first math class. Other studies of engineering students found engineers the most persistent of all college students (Ohland, et al., 2008) and that women persist at equal rates to men (Lord, et al., 2009). Our study expands the study population to the life and physical sciences and supports and extends some findings, but contradicts others.

We examined the advising records, math course grades, and graduation records of more than 3,700 STEM students in the 2001–2005 freshman cohorts at a large western university. Using logistic regression, we found that grade points earned in the first math class was the most accurate predictor (68%) in a two parameter model of graduation for all STEM disciplines. But contrary to Gardner's results, we found that which math course was first taken is also a strong predictor and that together they account for nearly all of the 71% prediction accuracy. Gender and STEM field pursued each provide a 0.5–1% increase in accuracy, mainly as interactions. We also found interesting differences between men and women outside engineering, especially in the life sciences where women are a majority.

AN ANALYSIS OF CONCEPTIONS OF INVERSE TRIGONOMETRIC FUNCTIONS

Vilma Mesa
University of Michigan
vmesa@umich.edu

Bradley Goldstein
University of Michigan
bradgold@umich.edu

This project attempts to identify the causes promoting the pedagogical difficulties associated with explanations of trigonometry and inverse trigonometry. Specifically, we seek to analyze how textbook presentation influences teachers' explanations and ultimately students' conceptions of the topic. We present a textbook analysis of conceptions of key ideas associated with inverse trigonometric functions using Balacheff's model of conceptions (Balacheff & Gaudin, 2010), as well as an analysis of a teacher's lectures on the subject and trigonometry and calculus students' interviews on a question addressing this topic

Our research pointed to several different conceptions of angles, trigonometric functions, and inverse trigonometric functions that may help explain the difficulties that trigonometry instructors and their students face with this topic. We found different types of problems that gave way to alternative conceptions and also different means of control that also gave way to alternative conceptions.

These difficulties may be explained in the following way: The conflicting conceptions can be traced back to a division within the textbooks between two representations of regular trigonometric functions. On one hand, these are seen as a direct translation from the x- and y-coordinates of the points at a given angle on the unit circle to the cosine and sine values, respectively, for those angle values. On the other hand, trigonometric relationships are sometimes represented as relationships between the sides of a right triangle. The unit circle method is generally viewed as a more 'advanced method' and one that fits better the changing real world because of the way it incorporates periodicity. When these inverse trigonometric functions are created from these two competing conceptions, fundamental differences arise between the arcsine of the circle method and the 'arcSine' of the ratio method.

This analysis of explanations given by the textbooks highlights the problematic way in which notions of inverse trigonometric functions are presented in the curriculum. This complex state of affairs in the textbooks certainly contributes to the teachers' conceptions of the material, as these same misconceptions were recorded in both the lectures and student interviews.

NEW STANDARDS, NEW PERSPECTIVES: THE PYTHAGOREAN THEOREM, DISTANCE FORMULA, AND LAW OF COSINES

Janine M. Viglietti
Buffalo State College
vigliejm@buffalostate.edu

Kristi Martin
SUNY Buffalo
krm33@buffalo.edu

Deborah Moore-Russo
SUNY Buffalo
dam29@buffalo.edu

The newly introduced Common Core State Standards for Mathematics (CCSSM) promote in-depth student explorations to encourage meaning making within mathematics classroom (Common Core State Standards Initiative 2010). This poster considers the restructuring of the mathematics curriculum by comparing the standards of six states and those included in the CCSSM. In order to effectively compare state standards versus the CCSSM, curricular revisions specifically related to the Pythagorean theorem, the distance formula, and the law of cosines were considered. The state standards for the three topics under consideration for California, Florida, Illinois, New York, Pennsylvania, and Texas were reviewed. These states represent a variety of geographic regions and, according to the U.S. Census, are the six highest populated states representing approximately 40% of the population as of 2010 (U.S. Census Bureau 2010). The researchers identified two primary research questions:

1. In what grades levels are the Pythagorean theorem, distance formula, and law of cosines introduced across states and in the CCSSM?
2. What explicit connections between topics do the authors of state standards and those of the CCSSM recommend?

Although the distance formula is an extension of the Pythagorean theorem in the coordinate plane, the standards for four of the six states considered here introduced these topics over a variety of grades (occasionally over courses that were nonsequential) potentially precluding the opportunity to foster a connection as each subsequent topic was introduced. Further, very few connections between the topics were suggested in any of the standards. Authors of the standards for five of the six states suggested introduction of the law of cosines as a formula to find an unknown side or angle with no mention of the Pythagorean theorem. In Pennsylvania the law of cosines was noted to be a generalization of the Pythagorean theorem.

In contrast, the authors of the CCSSM consistently indicated that teachers should be guiding students to notice and develop relationships between the Pythagorean theorem, distance formula, and law of cosines. As students advance to high school geometry the authors of the CCSSM intended that the concepts introduced with the Pythagorean theorem and distance formula be further developed, eventually culminating in work with the law of cosines. In particular the authors of the CCSSM highlight concept development and demonstration of meaningful connections between topics in the mathematics classroom. Future work will consider state standards and the CCSSM with respect to the mathematical shifts Fluency, Coherence, and Rigor.

QUESTIONING THE GENDER GAP IN MATHEMATICS: TESTING THE TEST

Rachel Voit
Macalester College
rvoit@macalester.edu

Christie Manning
Macalester College
cmanning@macalester.edu

Sashank Varma
University of Minnesota
sashank@umn.edu

Keywords: Gender, Measurement, Equity and Diversity, Cognition

For years, researchers have attempted to decipher the factors that contribute to the gender gap in mathematics. A growing body of research has provided evidence to suggest that contextual factors, as opposed to innate gender differences, are more predictive of students' mathematical achievement. Test item response format, conventionality (Gallagher, Holst, McGillicuddy-De Lisi, Morely & Cahalan, 2000), and instruction content (Anglin, Arson & Langer, 2008), in particular, have been shown to differentially influence male and female students' performance. Building on this research, the current study investigates how test item response format and other test-related factors influence the gender gap in mathematics.

Gallagher et al. (2000) showed that, on mathematics problems that demanded creative problem-solving techniques, female test-takers underperformed males. The authors suggested that this difference was a result of students' strategy choice. Anglin et al. (2008) found that mathematics performance in terms of accuracy and participants' ability to formulate unique problem-solving methods improved when students were primed to consider multiple strategies. These studies, in conjunction, suggest a meaningful relationship between strategy choice and accuracy in terms of mathematical achievement.

The current study uses a factorial design to examine the effects of test item response format (open-ended, multiple choice) and strategy priming (multiple, rigid) on participants' performance and choice of strategy (algorithmic, insight) as a function of sex (female, male). Forty-three undergraduates (21 males, 22 females) completed mathematics problems, half of which were open-ended and half of which were multiple choice. Instructional content primed participants' strategy choice by suggesting either multiple strategies or a single method. Students indicated their answer to the problem and their problem-solving strategy. A repeated measures ANOVA with two within-subjects factors, test item response format and strategy prime, and between-subjects factor, sex, revealed a significant interaction between response format and sex, $F(1, 41) = 9.571$, $p=.004$, $\eta 2 = .189$, on accuracy; females performed significantly better on multiple-choice questions than on open-ended problems, whereas males performed equally well on either format. There was also a significant interaction between response format and strategy prime, $F(1, 41) = .24151$, $p<.001$, $\eta 2 = .371$, on strategy choice. Participants used more insightful strategies on multiple-choice problems in the rigid condition than in the multiple strategy condition.

These results suggest that test format might differentially measure certain types of knowledge and, thus, inaccurately represent and characterize the gender gap in mathematics.

TASK ANALYSIS ACROSS DIFFERENT CONTEXTS IN CALCULUS I

Nina White
University of Michigan
whiten@umich.edu

Cameron Blum
University of Michigan
cvblum@umich.edu

Vilma Mesa
University of Michigan
vmesa@umich.edu

Keywords: Curriculum Analysis, Post-secondary Education

As part of the National Study of Calculus (Bressoud, Carlson, & Rasmussen, 2012), Tallman et al. analyzed 150 Calculus I exams from 253 submitted (Tallman & Carlson, 2012). They classified the problems they encountered with respect to Orientation, Representations, Format and opportunities to Model, Justify, and Explain. They found that 85% of the assessment items were procedurally focused and only 14% assessed understanding. We extend the work of Tallman and colleagues by using their framework to analyze both exams *and* homework at four community colleges selected by the same study as being successful. We narrow our focus to a few individual colleges, but analyze their curricular materials from across the entire semester. In this way, we reveal a more complete picture of students' opportunities to learn. We sought to answer the following research question: *What are the characteristics of homework problems and exam problems in a college Calculus I course?* In particular, we wanted to see how characteristics of homework and exam problems differ from each other and how characteristics of course problems differ longitudinally across the semester.

Our data thus far comprised 401 homework problems assigned during a semester of Calculus I and 71 exam problems included in three midterms and one final exam from one two-year college instructor. We coded the problems in five dimensions: Orientation, Prompt Representation, Prompt Response, Format, and Opportunities. We modified Tallman et al.'s framework in order to better classify the tasks we had in our data. We plan to apply this system to the data from the other three colleges in our sample.

We found that exam problems are less cognitively demanding than homework problems and use fewer representations. This observation is significant because it complicates the picture found by Tallman et al., who looked only at exam problems; we must also look at homework problems to fully characterize the kind of problems Calculus students encounter. It also raises the question: why are more cognitively demanding problems not included on exams?

We found that the textbook assignments from the chapters about limits and applications of derivatives had many examples of cognitively demanding problems, while, the chapters covering techniques of differentiation and integration, were mostly procedural problems. This reveals a potential orientation of the textbook, but also speaks to the way the instructor uses the textbook, and what skills she thinks are important for students to gain as they are related to different content areas in Calculus I.

YOUNG STUDENTS' EXPLORATIONS OF GROWING PATTERNS: DEVELOPING EARLY FUNCTIONAL THINKING AND AWARENESS OF STRUCTURE

Ruth Beatty
Lakehead University
rbeatty@lakeheadu.ca

Mary Day-Mauro
Simcoe Muskoka Catholic District School Board
marydm@smcdsb.on.ca

Kate Morris
Simcoe Muskoka Catholic District School Board
kmorris@smcdsb.on.ca

This study explored the development of early functional thinking in fifteen Kindergarten to Grade 2 students. As part of a teaching intervention that emphasized the co-variation between position numbers and number of items in each position of linear growing patterns, students were given a pre and post interview assessment to document their ability to predict the NEXT, NEAR and FAR terms of a pattern. Results of the interviews indicated that young students have the capability to recognize the relationship between two sets of values. Results also suggest that the recognition of visual and numeric structure in patterns influenced the extent to which students were able to reason recursively or explicitly. Finally, nine of the students developed the "perceptual agility" (Lee, 1996) to perceive the pattern in two ways. A "rows" perception was aligned with recursive reasoning, while a "columns" perception was aligned with explicit reasoning.

Keywords: Elementary School Education, Algebra and Algebraic Thinking

Early Years Algebra

In recent years there has been a shift in the research of mathematics education for young students from a focus on children's arithmetic thinking to the development of algebraic reasoning (Blanton & Kaput, 2002, 2003; Carraher & Schliemann, 2007). Researchers have begun to explore the kinds of learning experiences young students need in the elementary grades in order to develop algebraic thinking prior to formal algebraic instruction in high school. One area of research has been the study of elementary students' understanding of patterns and how this supports the development of functional thinking (Warren & Cooper, 2008).

Past research initially suggested that the connection between working with patterns to developing algebraic reasoning – that is, finding generalizations and expressing these as algebraic rules – is difficult even for students in middle and high school (English & Warren, 1998; Kieran, 1992; Lee & Wheeler, 1987; Orton et al., 1999; Stacey & MacGregor, 1999). One reason for this may be that current patterning curricula tend to emphasize the variation in only one set of data. For example, Figure 1 represents the kind of linear growing pattern found in elementary mathematics textbooks. Students from a young age are taught to focus on the systematic increase of tiles at each subsequent position of the pattern without thinking about the relationship between the tiles and their position in the pattern. Most students would describe and extend this pattern with the rule, "start with three red tiles and add two blue tiles each time". Asking for the 100th term highlights the problem of this method. Relying on this

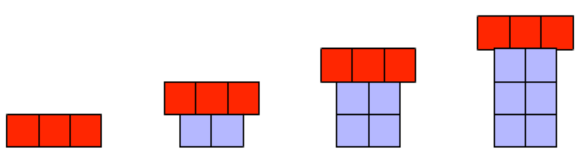

Figure 1: Growing pattern without position cards

recursive reasoning, adding two tiles to the previous term, makes it difficult to devise a general rule that would allow for the prediction of the number of tiles for *any* term of the pattern. Current instruction emphasizes this recursive reasoning by presenting growing patterns without term numbers, or with term numbers acting as labels for each term, but not as numeric quantities that can be used with a rule to determine the number of tiles.

More recently, researchers have been studying the potential of introducing specific pedagogical approaches to assist elementary students in developing algebraic reasoning through working with patterns (Rivera & Becker, 2008). Results of these studies have demonstrated the extent to which working with growing patterns can support students in developing algebraic thinking, particularly functional thinking, when the relationship between the term number and number of items at that term are emphasized during instruction (Beatty, 2007; Moss & McNab, 2011; Warren & Cooper, 2008). As an example, the pattern in Figure 2 represents the equation $y=2x+3$ with the coefficient represented by the blue tiles that increase by 2 at each term, and the constant represented by the red tiles that stay the same. The incorporation of term or position cards serves to help students identify the co-variation between one data set (i.e., the position number of each iteration) and another data set (i.e., the number of tiles at each position). The pattern rule, *number of tiles = term number x2+3* describes this relationship. Recognizing this relationship is referred to as explicit reasoning and allows for the prediction of elements far down the sequence and, ultimately, to identifying a general rule. Developing explicit reasoning is foundational to developing functional thinking, which is the perception of a generalization that relates two sets of objects.

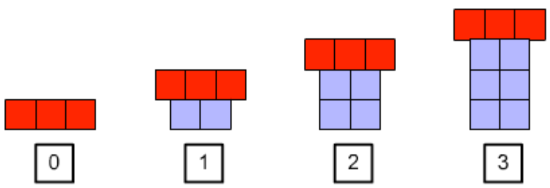

Figure 2: Growing pattern with position cards

Recent studies suggest that another important part of developing algebraic reasoning is the ability to identify mathematical structure (Mulligan et al., 2004; Mulligan & Mitchelmore, 2009). Linear growing patterns have both a numeric and geometric or visual structure. Students who focus on the numeric structure of the pattern in Figure 2 may attend to the fact that the elements at each position increase systematically (grow by 2) or that each element in the pattern is equal to twice the position number an additional three. Growing patterns also have a visual structure. Students who attend to the visual structure of the pattern may perceive it as composed of rows and/or columns of blue tiles with three red tiles on top. It is the development of an awareness of both numeric and visual structure, and identifying these as representations of a functional relationship, that supports algebraic reasoning.

There have been few studies that have looked at the potential to develop functional thinking in primary students (Moss & McNab, 2011; Warren, 2005; Warren & Cooper, 2008). The purpose of this exploratory study was to document how young students (Kindergarten – Grade 2) understand linear growing patterns. Specifically we were interested in the extent to which young students could accurately predict the NEXT (5^{th}), NEAR (10^{th}) and FAR (100^{th}) iteration of a linear growing pattern. Also of interest was whether these students would go beyond recursive reasoning to explicit reasoning by making the connection between the term or position number (the value of the position number) and the number of tiles at each position. We were also interested in how recognition of pattern structure (visual and/or numeric) influenced students' abilities to develop explicit reasoning.

Our research questions were:

1. Can working with linear growing patterns support students in making the connection between the position number and the number of elements at that position (going beyond recursive to explicit reasoning)?
2. Can young students generalize (in this context, can they accurately predict NEAR and FAR iterations of a linear growing pattern)?
3. What role does recognizing numeric or visual structure play in young students' mathematical thinking?

Methods

Setting and Participants

This study took place in four classrooms in two elementary schools (one Kindergarten class, one Grade 1 class and two combined Grade 1 & 2 classes). Five teachers were involved in the study including one Kindergarten teacher, one Grade 1 teacher, two Grade 1 & 2 teachers and one resource teacher. A short 5-lesson teaching intervention was designed to support students in making explicit connections between position numbers and numbers of items in each position, and to generalize by making NEAR and FAR predictions. During the instruction, attention was also paid to the visual and the numeric structures of linear growing patterns.

Data Sources and Analysis

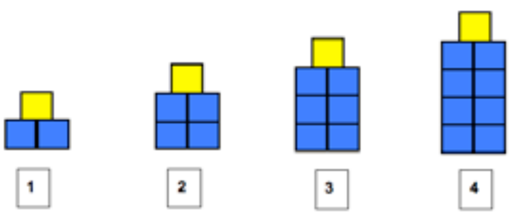

Figure 3: Interview Task Pattern

Individual task-based interviews were administered by the classroom teacher and recorded by the researcher. Fifteen students were interviewed (five Kindergarten, six Grade 1 and four Grade 2). The pre-interviews took place in December, and the post-interviews took place the following May. One of the interview tasks, the focus of this paper, asked children to describe and extend a linear growing pattern (Fig. 3) by building the 5th position. Students were asked to make NEXT (5th and 6th), NEAR (10th) and FAR (100th) predictions of the pattern. Transcriptions of the video recorded interviews were coded with respect to students' abilities to 1) identify predictable growth and constancy, 2) accurately extend the pattern, a NEXT prediction, 3) make accurate predictions down the sequence (NEAR 10th position or FAR 100th position). Transcriptions were also coded with respect to whether students recognized the numeric structure of the pattern, the visual structure of the pattern, and how recognition of structure supported an ability to make accurate generalizations.

Results

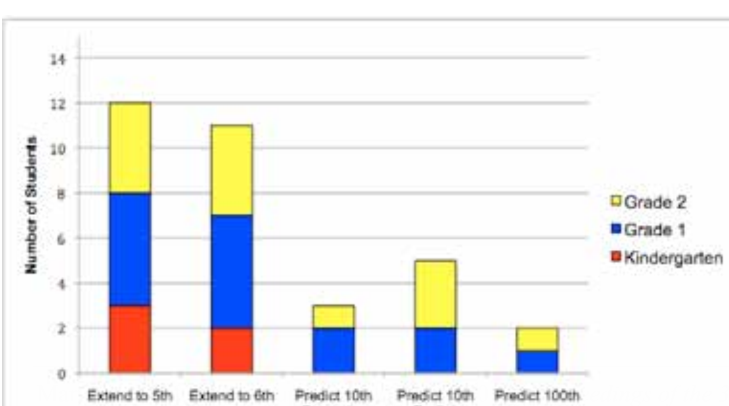

Figure 4: Pre-Interview Results

Pre-Interview Results. Results for the pre-interview are presented in Figure 4. As shown in the graph, most students were able to accurately extend the pattern to the 5th and 6th term. Seven of the students (including all of the Kindergarten students) were unable to make accurate numeric or geometric predictions about NEAR and FAR terms

in the pattern, which suggested difficulty in recognizing the structure of the pattern either visually or numerically. However, eight of the fifteen students made accurate NEAR predictions using either recursive or explicit reasoning, and two students made accurate FAR predictions. We analyzed the thinking of these students to understand their reasoning.

NEXT predictions. Twelve of the fifteen students recognized that the pattern was increasing by two tiles each time, and extended the pattern by adding two more blue tiles, or by counting on from the 8 tiles at position 4. However, none of the Kindergarten and only three of the Grade 1 students could articulate how they knew how to build the 5th position. For example, Jesse (Grade 1) accurately built the 5th position, but stated that he "built a big pattern and all the tiles are blue. Blue, blue, blue, blue, blue, blue, blue, blue, blue, blue and one yellow." Jesse had only been exposed to repeated patterns, which are typically described by articulating the attributes of the pattern that repeat, for example, red, yellow, red, yellow. Although Jesse was accurate in his building, he was unable to quantify the growth of the pattern.

NEAR prediction using recursive reasoning. When predicting the 10th position two Grade 1 and one Grade 2 students employed recursive reasoning to determine the correct number of tiles. These students focused on the numeric structure, the fact that the pattern increased by two blue tiles each time, but when building the 5th term their visual patterns differed from the task pattern. For example, Isabelle (Grade 2) created an incomplete 3x4 array at position 5 using one yellow and ten blue tiles. When asked to predict the number of tiles for the 10th position, she coordinated two internal number lines to skip count by 2s (to represent adding 2 tiles each time) and simultaneously counted up by 1s (to keep track of the position number). She did this without using physical position cards or tiles.

Isabelle: [Pointing to the 5th position card – which had no tiles] 5…ten, 6 would be twelve [still pointing at the 5th position card because there are no other position cards on the table] [shifts her finger to the right of the 5th position card] 7 would be fourteen [shifts her hand to the right again] 8 would be sixteen, um 9 would be eighteen, and 10 would be twenty! Twenty blue and one yellow!

Isabelle incorrectly predicted that the 100th term would have 102 tiles.

NEAR and FAR prediction using explicit reasoning. Two Grade 1 and three Grade 2 students perceived the numeric structure of the pattern and recognized that the value of the tiles was double the value of the position number. They were able to predict the number of tiles at the 10th position using this reasoning, for example "because 10 plus 10 equals 20 blue and then one yellow." Three of these students were unable to make a FAR prediction and we observed that they were unable to accurately build the 5th and 6th position of the pattern (they used the correct number of tiles, but placed them randomly at each of the positions). This suggests that, although they understood the numeric structure of the pattern, these three students did not attend to the visual structure.

Two of these students (one Grade 1 and one Grade 2) built 5th positions that matched the other iterations of the task pattern. These students made accurate FAR predictions. For example, Chloe (Grade 1) explained the relationship she saw between the position card and the number of tiles when predicting positions of the pattern.

Teacher: How did you know there were going to be ten blue tiles at the 5th position?

Chloe: Because the ones on the top [touching the tiles] it's what they equaled. Like 1 plus 1 equals 2 [pointing to position cards and tiles], and 2 plus 2 equals 4, 3 plus 3 equals 6, and 4 plus 4 equals 8. So this one [pointing to the 5th card] would be 10 blue and one yellow. Because you look at the [position] card and that's what it equals.

Teacher: How about at the 100th position?
Chloe: 200 blue and one yellow.
Teacher: What about at the thousandth position?
Chloe: Two thousand blue and one yellow.

Post Interview Results

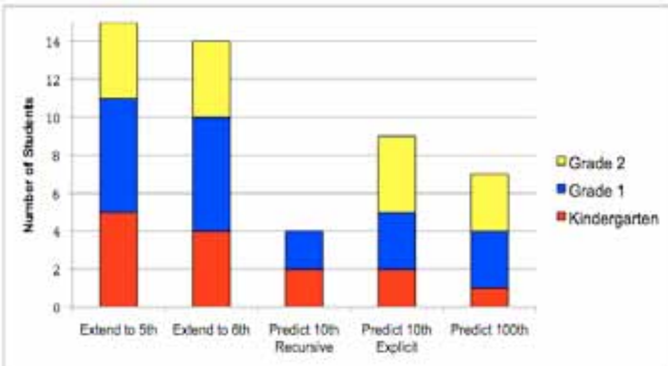

Figure 5: Post Interview Results

Results of the post interviews are shown in Figure 5. As shown in the graph, more students were able to make accurate NEXT, NEAR and FAR predictions during the post interview, and more students used explicit reasoning when making their predictions.

NEXT and NEAR predictions using recursive reasoning. When making NEXT predictions, six of the students demonstrated recursive reasoning that combined an understanding of the numeric structure (increasing by two) with a perception of the visual pattern structure as increasing rows of two tiles. Four of these students continued to use recursive reasoning to make NEAR predictions.

NEXT, NEAR and FAR predictions using recursive *and* explicit reasoning. When making NEXT and NEAR predictions, nine students used both recursive and explicit reasoning based on a shifting perception of the visual structure of the pattern (Figure 6). One perception, the rows perception, demonstrated an understanding that the pattern was increasing by successive increments of 2. This was evident when students justified their predictions either by stating the pattern "goes up by 2 each time" or by skip counting by 2s. Simultaneously these students saw the pattern structure as two columns of tiles with each column composed of a number of tiles equal to the position number. This perception was aligned with explicit reasoning as students justified their predictions by making connections between the position number, and the number of tiles in each column of the pattern. During the interviews, these students went back and forth between these two perceptions.

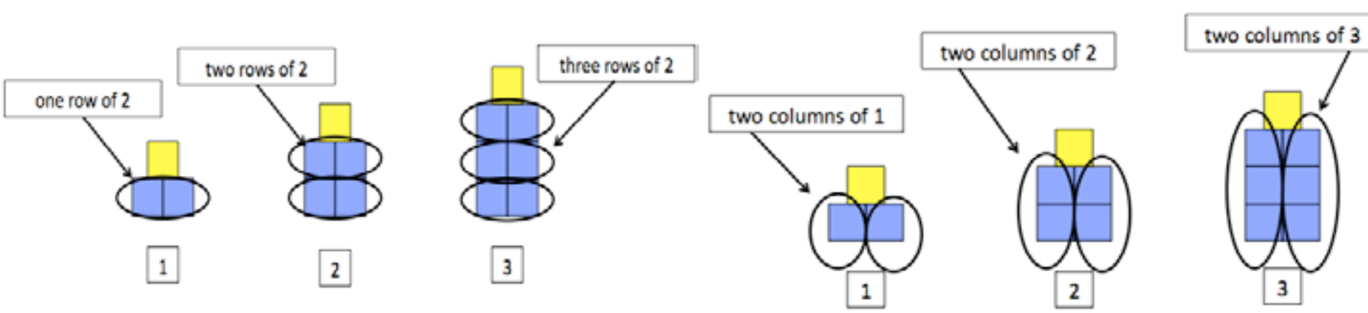

Figure 6: Two Pattern Perceptions

For example, Jesse (Grade 1) demonstrated how he used both the perception of the pattern as growing by one row of 2 tiles at each term, and of the pattern as two columns of tiles (with each

column equal to the value of the position number) to make his predictions and justify his reasoning.

Teacher: [Built the first three positions]. How many am I going to need in the fourth position?
Jesse: Eight blues and one yellow! Because I know that for this one [pointing to the third position] you were going to put six because three plus three equals six [pointing to the two columns of three tiles]. And four plus four [pointing to the position card] is eight [pointing to the two columns of 4 tiles].
Teacher: What would you build in position 5?
Jesse: [Mouthing five plus five] ten!
Jesse then built the 5th position.
Teacher: How did you know how many tiles went in the 5th position?
Jesse: [Jessie uses two fingers to count by 2s from the bottom pair of tiles to the top pair.) Because you go 2,4,6,8,….then 10! Going up by twos!
Teacher: How many blue tiles would you need for the 10th position?
Jesse:[Points to position card 10] Ten plus ten is 20!

Six of the students also used the columns perception when making FAR predictions. For example, Ava (Kindergarten) took a column approach when the teacher asked her to predict how many blue tiles there would be at the 100th position and indicated that "there would be 100 up one side and then another row of 100, so two hundred blue and a yellow."

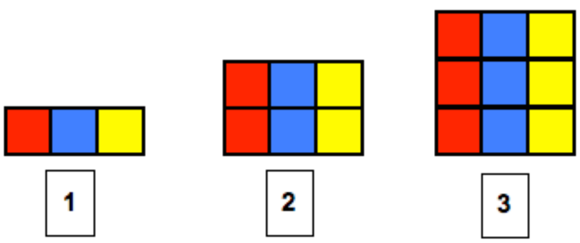

Figure 7: Ava's Pattern

To further probe her thinking, Ava was asked to build a pattern. She constructed a growing pattern with one column of red tiles and a column of blue tiles (Figure 7). The number of tiles in each column was equal to the number on the position card. The teacher then added a third column of yellow tiles and built the pattern to position 3. She asked Ava to predict how many tiles would be needed for the 10th position. Immediately Ava said, "Thirty!"

Teacher: How did you know that?
Ava: Counting by 10s! Ten, twenty, thirty!
Teacher: So if you had four colours, how many tiles would you have at the 10th position?
Ava: [laughs] Forty!
Teacher: What else that can you tell me?
Ava: If there's five colours, then fifty!

Discussion

The results of the pre-interview indicated to us that young students have the potential to work with growing patterns in a meaningful way, and can successfully focus attention on the relationship between two sets of data such as position cards and tiles. The initial analysis of the pre-task results indicated that eight of the fifteen students accurately made NEAR predictions based on their recognition of the numeric and/or visual structure of the pattern. After working through a series of five lessons that specifically focused on identifying the relationship between position number and number of items at the position, and the numeric and physical structure of linear growing patterns, we saw an increase in the number of students who demonstrated an ability to recognize and describe predictable growth, extend a linear growing pattern accurately,

and make NEAR and FAR predictions. During the post-interview thirteen of the fifteen students were able to make NEXT and NEAR predictions, and seven were able to make FAR predictions. This indicates that the initial difficulties some students experienced may have stemmed from a lack of experience, and not from a lack of capability. Their earlier instruction has focused almost exclusively on repeating patterns, which influenced their initial work with growing patterns. This was evidenced by such practices as describing the growing pattern as a repetition of one variable (for example, Jesse's description of the fifth position by articulating the word "blue" ten times).

Although this was an exploratory research project, and the teaching intervention was relatively brief, our results suggest that even very young students may be capable of functional thinking – an idea first posited by Blanton and Kaput (2004). There were some critical components of the teaching sequence that may have supported this capability. During the lessons an emphasis was placed on the relationship between the position number and number of tiles (or other elements) at each position. Students were also asked to make predictions from the NEXT term to NEAR and FAR terms in order to focus on the relationship between the two. Another important component was the use of arrays to represent different growing patterns, and the connection between the position number and number of "groups" in the array. Unlike typical pattern instruction for this age level, the instruction emphasized multiplicative rather than additive thinking, which is necessary for developing an understanding of functional relationships.

Of interest was the "perceptual agility" (Lee, 1996) demonstrated by nine of the fifteen students when making their NEXT, NEAR and FAR predictions. Perceptual agility is the ability to perceive a pattern in multiple ways, and utilize one or more perception as the basis for making generalizations. Because we had incorporated the use of arrays into our instructional design, students developed two ways to consider the growing pattern used during the assessment interview. As the teacher built the pattern for the interview task, she emphasized the series of rows of two tiles. However, the students were able to perceive it as either a pattern of increasing rows of two, or as a pattern of two columns of tiles equal to the position number. The "rows" perception seemed to be connected to recursive reasoning, adding a row of two more tiles each time. Students with this perception considered the variation in one data set and identified the recursive relationship within the pattern. The "columns" perception, on the other hand, seemed to allow students to make the leap to explicit reasoning by considering the pattern as two columns with each column composed of a number of tiles equal to the position number. Students identified the relationship between the position number and the number of elements at each position as evidenced by their ability to make NEAR and FAR predictions without having to rely on "adding two more tiles each time." This was demonstrated by Ava's recognition that at the 10^{th} position of the pattern that she built, if she had 5 colours of tiles there would be 50 tiles. Rather than thinking of ten groups of 5 (rows), she was clearly thinking of 5 groups of 10 (columns) and used that perception in her prediction.

Also of interest is the development of an awareness of visual and numeric structure. This was evident as we analyzed the change in students who had trouble making NEAR and FAR predictions during the pre-interview. Some students could extend the pattern in a way that was visually accurate with two columns of blue tiles and one yellow tile on top, but was not accurate numerically. Other students could make numeric NEAR predictions, but did not represent the visual structure of the pattern accurately, which hampered their ability to make FAR predictions (most of these students predicted 102 tiles would be needed for the 100^{th} term). During the post-interviews, all of the students who made accurate NEAR and FAR predictions had developed an

ability to recognize both the visual and numeric structure of the pattern. This is important because previous research suggests that the ability to recognize both numeric patterns and visual pattern structure are key elements in developing algebraic reasoning (Arcavi, 2003; Berch, 2005; Mulligan & Mitchelmore, 2009; Papic et al., 2011).

INVESTIGATING INTEGER ADDITION AND SUBTRACTION: A TASK ANALYSIS

Laura Bofferding
Purdue University
LBofferding@Purdue.edu

Sue Ellen Richardson
Purdue University
richa114@purdue.edu

Fifteen elementary and secondary teacher candidates solved sixteen integer addition and subtraction problems during think-aloud interviews. Investigators further probed participants' solution strategies as well as what they noticed first when starting a new problem. Task analyses of participants' solutions led to the creation of two distinct maps detailing the procedural relations among and conceptual elements underlying the six problem types. The task analysis results indicate that participants relied on procedural knowledge and had weak strategic knowledge with little focus on number values in their four main solution strategies. These findings highlight possible areas for instruction to support conceptual understanding.

Keywords: Number Concepts and Operations, Cognition

Purposes of the Study

Students' transition from working with whole numbers to integers in middle school causes cognitive dissonance. They have to reinterpret the meaning of the minus sign (Bofferding, 2010; Vlassis, 2004) and the meanings of addition and subtraction (Bofferding, 2010; Bruno and Martinon, 1999), both of which play a role in how they solve integer problems (Bofferding, 2012). Researchers have explored the relative difficulty of integer problems based on percent correct data and detailed some of students' difficulties in solving the problems (e.g., Murray, 1985); however, their descriptions of students' solution methods are inconsistent, incomplete, focus on a few problem types, and/or pertain to specific contexts. Moreover, the existing studies provide little explanation for how students correctly solved problems or whether their solutions were mathematically rich. Lack of detail regarding students' solutions is troublesome because students can get correct answers to integer problems using incorrect methods (Tatsuoka, 1983).

Developing a classification scheme of integer problems and typical solution paths that students take to solve these problems could unite research efforts in this area. Certain solution paths may draw on procedural thinking while others tap into more complex types of knowledge (e.g., schematic or strategic); such information has important instructional implications. Further, a detailed framework could help teachers develop models of their students' thinking processes and better equip them to adjust their instruction to build on students' knowledge, as was found with Cognitively Guided Instruction (Carpenter, Fennema, Peterson, Chiang, & Loef, 1989).

Research Questions

This paper begins to address these issues by exploring the processes and knowledge involved in solving integer arithmetic problems. Specifically, we explore the following questions:

1) What are the processes through which teacher candidates (who may later teach this topic) solve integer addition and subtraction problems?
2) What knowledge (declarative, procedural, schematic, strategic) do students use to solve the integer problems, and how does this relate to the thinking processes students use?

Theoretical Framework

Negative Number Instruction

One area of insight into how students might solve integer problems comes from the

instruction they receive. Two typical methods for teaching addition and subtraction with negative numbers are movements on the number line and cancellation. Common rules for moving on the number line include the following: when you add, move forward; when you subtract, move backward; if you are adding or subtracting a positive number, face the positive numbers; if you are adding or subtracting a negative number, face the negative numbers (Liebeck, 1990). Given these rules, a student would likely start at whatever number is first in the problem, pretend to face the direction of the second number's sign, and then move up (forward) or down (backward) on the number line or counting sequence.

A common way to think about cancellation is through the use of chips, where 1 positive chip cancels out 1 negative chip. People who use this method might focus on the amounts of the two numbers in the problems. Further, they will need to have rules for dealing with situations when they have to take away more positives or negatives than are originally given (e.g., -3 - -5) (Liebeck, 1990). Other forms of cancellation instruction use different contexts for exploring the canceling operations, such as colored beads on a double abacus (Linchevski & Williams, 1999), cutting and gluing input and output trains (Schwarz, Kohn, & Resnick, 1993), and adding and removing balloons and weights to a hot air balloon (Janvier, 1985); however, the rules remain the same.

Results from instructional and interview studies provide a sample of strategies students use to solve integer problems. For example, to solve -4 + -3, a student might add 4+3=7 and then add a negative sign to get -7 (Bofferding, 2010). Students might also count down to solve problems like 3-5 (Bishop, Lamb, Philipp, Schappelle, & Whitacre, 2011). Tatsuoka (1983) created a system to classify students' response patterns (particularly in terms of their erroneous rules) to a series of integer problems based on possible rules students might use to manipulate the absolute values and signs of the numbers. Although they might not directly match students' thinking, results such as these can be used as a starting place for developing a map of how students solve integer problems.

Task Analyses

Another way researchers have attempted to characterize students' solution processes for solving mathematics problems is through the use of task analysis, "a decomposition of a complex task into a set of constituent subtasks" (Gardner, 1985, p. 157). Recent task analyses – such as the work of Piaget and others – focus on analyzing students' mental processes and conceptions as they engage in tasks (see Resnick, 1976, for a more detailed description of the history). Thus, task analysis is a useful tool in cognitive research (Siegler, 2003) for mapping out the procedures students use and highlighting the conceptual knowledge needed to solve problems (Greeno, 1976).

There are several reasons why task analyses are necessary (especially if modeled after students' solution processes). First, they identify conceptual prerequisites or structures that underlie instructional outcomes (Anderson & Schunn, 2000; Greeno, 1976). For example, Griffin, Case, and Capodilupo (1995) identified that knowledge of number order (such as on a number line) serves as an essential support for other number concepts; they found that when given explicit instruction on the number line, low-performing students caught up to their high-performing peers in mathematics. Task analyses can also be used to determine where students are likely to deviate from correct procedures, which can help teachers target instruction (Anderson & Schunn, 2000). Additionally, from a series of related arithmetic problems, researchers can use task analysis to determine which problems elicit more potential methods and which strategies are most efficient. This information can help instructors identify problems that

might engender better classroom discussions about strategies.

Mathematical Proficiency and Knowledge Types

Not only are the processes through which people solve mathematics problems important but so are the types of knowledge they use in relation to the strands of mathematical proficiency, which is our goal for students in mathematics classes (National Research Council, 2001). The first strand, conceptual understanding, relates to understanding why a procedure works and can help students avoid errors. Further, students with conceptual understanding "understand why a mathematical idea is important and the kinds of contexts in which it is useful" (National Research Council, p. 118). Students with procedural fluency, the second strand, know when and how to use procedures to solve a wide range of problems efficiently and accurately; students who use procedures without conceptual understanding are likely to make errors and lack procedural fluency (National Research Council). Strategic competence, the third strand, involves understanding problems and knowing which strategy is best to use. Further, students with strategic competence understand how problems are related. Adaptive reasoning is the fourth strand, which refers to students' ability to justify their answers, and the final strand, productive disposition, includes "see[ing] sense in mathematics" (National Research Council, p. 131).

The four types of knowledge underlying these interwoven strands require different amounts of cognitive demand. Declarative knowledge is knowledge of facts, which are memorized and recalled. Procedural knowledge requires more cognitive effort and involves knowing the steps for solving a problem. On the other hand, schematic knowledge involves knowing why certain processes or strategies work. Finally, strategic knowledge, or knowing about knowing, includes monitoring one's own knowledge and knowing when a particular strategy is the optimal one to use (Li, Ruiz-Primo, & Shavelson, 2006).

Methods

Participants and Site

Participants in the study included fifteen teacher candidates (8 secondary-focused, 7 elementary-focused) taking courses in a teacher education program at a Midwestern state university. All had taken some mathematics content courses at the undergraduate level. Two of the secondary student participants were male, while the remaining thirteen people were female.

Materials and Data Collection

In order to access the teacher candidates' solution methods as they solved the integer problems, we conducted individual think aloud interviews. Participants were asked to "say everything that you might say to yourself silently or think in your head" as they solved 16 naked number addition and subtraction problems involving integers (see Table 1). Although the use of think-alouds slows processing time when solving problems, they do not change their thinking (Ericsson & Simon, 1993; Ericsson, 2006). Participants started with a practice question to get used to talking out loud while solving the problems. One or two researchers conducted each interview and took notes about participants' solutions. Follow-up questions asked after they solved all of these problems included clarifying questions about their strategies as well as the following: "Which questions were the easiest? Why?" and "When you looked at a new problem, what is the first part you noticed? Which part is most important? Why?" Their work for each problem was collected, and interviews were audio and videotaped, then transcribed.

Data Analysis

To analyze the data, we first developed an initial task analysis of the steps we thought were needed to solve the problems based on accounts of students' strategies in the research and the common ways of teaching integer addition and subtraction. The task analysis was adjusted

throughout the coding process, based on participant responses. Rather than making separate task analysis maps for each procedure students might use, we combined them into a nondeterministic map; therefore, a student could take one of many paths through the map (Greeno, 1976).

During the coding process, we found that determining how people were “starting” the problem, or what they noticed first, was too open to interpretation to be used as the first step in the task analysis. Therefore, we reorganized the analysis based on identifying the problem type as the first step. As we read the transcripts of each participant’s solution steps, we coded each step in their processes based on the final task analysis maps. We double-coded about 20% of the naked number problems with >85% agreement, then discussed differences, and coded another 14 problems with >90% agreement.

Table 1. Integer Problems Solved and Organized by General Problem Type

Addition: Two Negatives	Addition: Negative, Positive	Subtraction: Negative, Positive	Subtraction: Two Negatives	Subtraction: Two Positives
-7+-1	-2+7, -4+6	-3-5, -5-9	-4 - -7, -6 - -9	3-9, 6-8
	-9+2	4 - -5	-8 - -5	
	5+-2	5 - -3, 9 - -2	-8 - -8	

Results

Task Analysis

The final task analysis consists of two maps, showing the six general problem types (those shown in Table 1, as well as Addition: Two Positives), the relations among them, and branches showing the sequential steps participants made when solving problems of these types. Map 1 consists of addition of two positive numbers, subtraction of a positive and negative number, and addition of two negative numbers. These problems are related because problems of one type can be changed into one of the other types using sign rules (e.g., 5+3 is equivalent to 5 - -3, and -2-7 is equivalent to -2+-7). Map 2 consists of subtraction of two positive numbers, addition of a positive and negative number, and subtraction of two negatives. The problems are also related (e.g., 3-9 is equivalent to 3+-9, which is equivalent to -9 - -3). If a person solved -2+7 by identifying the first number as negative, switching the order of the numbers (7+-2), and changing the operation using sign rules (7-2), the map would show the following connections: Addition, Negative and Positive → 1st Number Negative → Commute → Change to Subtracting a Positive → Subtraction, Two Positives → Recall.

Solution Processes by Problem Type

Based on coding from the task analysis, certain problems stand out as related based on the similar ways in which the participants solved the problems. Across participants, the most consistently solved problem type was subtracting a negative number from a positive one (4 - -5, 5 - -2, and 9 - -2). For all three of these problems (except in 1 instance), they identified the second number as negative, changed the problem into adding a positive, and recalled the answer.

Results for subtracting a positive number from a negative one were less consistent. J02 nicely explained how she solved -3-5: “I'll make the five a negative, instead, and so then all I have to do is add the actual numbers together and then just make sure that the sign after that is negative.” Most participants used this reasoning – solving the problem as they would if adding two negatives – for both -3-5 and -5-9. However, two people for -3-5 and five people for -5-9 focused on number order, starting at the negative number and counting down as they would for a normal subtraction problem. One of them thought of this as a hole that was getting deeper.

Subtracting a larger number from a smaller one (3-9 and 6-8) also had fairly consistent responses from participants. The most popular response was to indicate that the larger number was second, subtract the smaller from the larger, and make the answer negative. On 6-8, A05 used zero as a landmark number: "I'll go back 6, then I'll be at 0. Then I'll have 2 more to go, so that's -2." One person for 3-9 and two for 6-8 changed the problems into adding a negative (3+-9 and 6+-8) then either recalled the answer, started at the negative number and counted toward zero, or canceled equal numbers of positives and negatives to get the resulting negative answers.

Although -2+7, -4+6, -9+2, and 5+-2 appear similar because they involve adding a positive and negative number, participants treated -9+2 very differently. For the other three problems, participants typically changed the problems into subtraction by using the commutative property to switch the order if needed (7+-2 and 6+-4, although only a few verbalized this step), changing the problem into subtracting a positive (7-2, 6-4, 5-2), and recalling the answer. Similarly, when solving -4 - -7 and -6 - -9, participants first changed these into adding positive numbers (-4+7 and -6+9) and then followed the same steps.

Changing -9+2 into a subtraction problem was rare because the number with larger absolute value was negative, and in general, the participants did not choose to subtract larger numbers from smaller ones. Instead, on this problem, they either started at -9 and counted up 2 or subtracted 2 from 9 and used the sign of the number with the larger absolute value, reporting the answer -7. Likewise, when solving -8 - -5, students first changed the problem into adding a positive number (-8+5) and followed the same steps as -9+2.

These results present a much more complicated picture of the interrelationships among the problems (see Figure 1) than shown in Table 1. Solid lines indicate problems that are part of the same category from Table 1. Solid arrows indicate problem types that can be changed into each other, and dotted arrows indicate problem types that can be solved using similar processes.

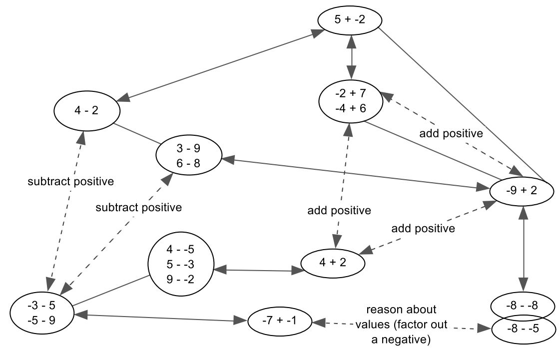

Figure 1: Relations Among Problems

Participants' Solution Process Consistency

Although solutions for the problems were fairly consistent, participants approached the set of problems in four main ways. Five of the participants (A01, A03, A06, O01, R02) solved problems in a way that suggests they preferred to solve problems with *all positive or all negative numbers*, unless it made the problem more complicated. For example, when solving -2+7, they changed the problem into 7-2. In some cases they did not explicitly change -9+2 because they knew the answer or because they knew they could solve 9-2 and add a negative sign. For -3-5 and -5-9 they solved them as addition (-3+-5), adding the absolute value of the numbers and making the answer negative. Also, although problems like -4 - -7 contain two negative numbers, participants still changed them to the form 7-4.

A second group of participants (A02, A05, A04, K01, K02, R01) solved or changed problems so that they could *add or subtract positive numbers*. Therefore, although all of them changed 5+-2 into 5-2, none of them changed -9+2. Further, none of them changed -3-5 or -5-9; instead, they talked about starting at the negative number and going back the positive number

value. The two participants who talked about solving -3-5 and -5-9 by adding the absolute value of numbers and making the answer negative also changed -7+-1 into -7-1 before solving it.

Participant K03 had a different approach than the others; she changed problems so that she could always *add positive and/or negative numbers* because she mainly used a cancellation strategy. She kept -2+7, -4+6, -9+2, and 5+-2 as is and reasoned about the relative number of positives versus negatives to determine what would be left over if each positive cancelled out a negative. Further, she changed 3-9 and 6-8 into 3+-9 and 6+-8 and changed problems like -4 - -7 into -4+7 using sign rules in order to use the same cancellation strategy. For the other problems, she either added two positive numbers (e.g., 4 - -5 became 4+5) or added two negative numbers (e.g., -3-5 became -3+-5, and -7+-1 stayed the same).

Unlike participant K03 and the others, participant J02 primarily focused on starting with the number of larger absolute value. When the number of smaller absolute value was first, she changed the format of the problem. For example, on 6-8, she changed it to 6+-8 and then further changed it to -8+6. However, when solving -2+7, she flipped the numbers to 7+-2 and also changed it to 7-2. This suggests she preferred adding positive numbers, which is confirmed by her statement, “I think adding is easier than subtracting, trying to subtract negative numbers.”

Finally, O02 and J01 did not use a consistent way to solving the problems. For example, they both solved -4+6 by starting at -4, adding the opposite (4) to get to 0, and determining the answer was 2. However, on a similar problem, -2+7, they changed it into 7-2.

Knowledge Types

Overall, participants drew heavily on procedural knowledge when solving the problems; however, they sometimes lacked procedural fluency due to insufficient schematic knowledge. For example, several participants changed problems such as 5 - -3 into addition problems by drawing vertical lines through the minus and negative signs (5 + + 3). When asked how they knew they could do this, they referred to declarative rules rather than conceptual explanations: “When you have two minus signs you can put them together to make a plus sign” (A02) or “You can slash it but then you dash it…cause the minus minus makes a plus” (A06). When asked, “That’s just a rule that you know?” most agreed and restated the rule or indicated that they were told this rule as a child, and one replied, “The theory behind that, I don’t [know].” The one participant who was more successful at explaining how subtracting a negative was similar to adding a positive drew on a description of negative amounts as holes underground, explaining, “Subtracting a negative number, so that's like subtracting part of a hole, which is like adding” (A04).

In limited cases, participants’ lack of schematic or conceptual knowledge led them to change the problems incorrectly (solving -9+2 as 9-2) or use sign rules incorrectly. For example, one participant changed -2+7 into 7-2=5 and answered negative five, claiming, “Because I’m taking away from a negative number,” suggesting she may have thought 7 was negative originally or that because -2 was the first number in the original problem, the answer should be negative.

One of the most striking patterns in participants’ responses was their lack of focus on the values of the numbers, resulting in inefficient methods and suggesting weak strategic knowledge and possibly a lack of conceptual understanding of integers. For -8 - -8, only one person stated that “When you subtract a number from itself you get zero” (A02). All others changed the problem to -8 + 8, and rather than use the additive inverse property, two people further changed the problem to 8-8 before answering 0. Further, although participants solved -7+-1 by solving 7+1 and adding a negative, they never used the same reasoning to solve -8 - -5 as -(8-5).

Discussion and Implications

The results of the task analysis and participant responses illuminate ideas that teachers need to keep in mind when teaching about integers and suggest concepts that students need to know as they learn integers. A prominent way that the participants solved the problems was to change the problems into a different form. Some of them used the phrase "slash and dash" to remember when and how to change the problems, but they had difficulty explaining the meaning behind it. The National Research Council (2001) warns against this type of operating:

> Mnemonic techniques learned by rote may provide connections among ideas that make it easier to perform mathematical operations, but they also may not lead to understanding. These are not the kinds of connects that best promote the acquisition of mathematical proficiency (p. 119).

Rather, if we want students to develop conceptual understanding of integer operations, teachers need to know how to help students meaningfully explain the relation between the operations.

One potential way teachers can help students make these connections is through the use of contexts or the number line. Stephan and Akyuz (2012) successfully used the idea of net worth to help students make sense of losing debt as gaining overall net worth. Further, participants in the study were able to use movements on the number line to add or subtract positive numbers from negative ones. However, they did not use it to add or subtract negative numbers, suggesting that number line instruction needs to address these situations more effectively. By using the number line, the holes context, and cancellation reasoning, some participants broke up numbers in strategic ways, making zero and then adding or subtracting the rest. This method promotes numerical reasoning and works for many problems – especially when changed into the form of adding a positive and negative number – and highlights the importance of zero.

There were a few concepts in particular that participants used frequently and that would likely be important for students to know as they begin to work with integers: relative number values (including number order) versus absolute values and the commutative property. When solving problems, such as -9+2, some participants decided whether the answer would be closer to or farther from zero based on the relative values of the two numbers. On the other hand, when adding a positive and negative number, participants often compared the absolute values of the two numbers to determine if there was enough of the positive number to cancel out the negative number or to move from the negative number through zero. Knowledge of opposites also helped participants solve -8 - -8 as -8+8; however, a stronger focus on number values could have helped them solve the problem more efficiently.

Participants used the commutative property when they changed problems like -4+6 into 6-4; however, they rarely explained this intermediary step (6+-4). In fact, they never explained why they could solve -9+2 as -(9-2) either. When discussing these processes with students, teachers would need to be more explicit about the reasoning behind these steps or students might develop misconceptions about the operations and sign, such as believing -9+2 could be solved as 9-2.

Exponential functions are important topic in school algebra and in higher mathematics, but research on students' thinking suggests that understanding exponential growth remains an instructional challenge. This paper reports the results of a small-scale teaching experiment with students who explored exponential functions in the context of two continuously covarying quantities, height and time. We present two major conceptual paths that occurred in the development of an understanding of exponential growth, the covariation view and the correspondence view, and discuss the influence of each perspective on the growth of students' understanding.

Keywords: Algebra and Algebraic Thinking, Learning Trajectories, Middle School Education

Introduction

Exponential functions are an important concept in school algebra, representing a significant transition from middle school mathematics to the more complex ideas students encounter in high school. A focus on the conceptual underpinnings of exponential growth has increased in recent years; for instance, the Common Core State Standards in Mathematics (2010) highlight the need to understand exponential functions in terms of one quantity changing at a constant percent rate per unit interval relative to another. Moreover, these ideas also now appear at the middle school level, both in terms of national standards as well as in middle school curricula (e.g., Lappan et al., 2006).

Implementing this vision, however, may prove challenging given students' documented difficulties in understanding exponentiation. Students struggle to transition from linear representations to exponential representations, to identify what makes data exponential, or to explain what a function such as $f(x) = a^x$ means (Alagic & Palenz, 2006; Weber, 2002). Pre-service teachers have not fared much better, struggling to recognize growth as exponential in nature, to connect a repeated-multiplication understanding to the closed-form equation, and to generalize the rules of exponents (Davis, 2009). In general, understanding exponential growth appears to be challenging for both students and teachers (Davis, 2009; Weber, 2002).

These documented challenges suggest a need to better understand how to foster students' learning about exponential growth, particularly in a way that goes beyond merely highlighting the skills students should acquire. This paper reports on the results of a teaching experiment emphasizing exponential growth in the context of two continuously covarying quantities. We introduce two major conceptual paths that occurred in the development of an understanding of exponential growth, the covariation view and the correspondence view, and discuss the influence of each perspective on the growth of students' understanding.

Background and Theoretical Framework

The Rate-of-Change Perspective

A popular approach to function relies on the correspondence perspective (Smith, 2003), in which a function is viewed as the fixed relationship between the members of two sets. Farenga and Ness (2005) offer a typical correspondence definition of function: "One quantity, y, is a function of another, x, if each value of x has a unique value of y associated with it. We write this as $y = f(x)$, where f is the name of the function" (p. 62). This static view of function underlies much of school mathematics, in which a focus on developing correspondence rules between x and y enables students to solve prediction problems, construct and interpret graphs and tables, and determine roots and missing values.

Smith and Confrey (Smith, 2003; Smith & Confrey, 1994) offer an alternative to the correspondence view, which they call the covariation approach to functional thinking. Here one examines a function in terms of a coordinated change of x- and y-values, where moving operationally from y_m to y_{m+1} is coordinated with movement from x_m to x_{m+1}. Confrey and Smith (1995) have found that students' initial entry into a problem is typically from a covariational perspective; moreover, viewing a function as a representation of the variation of quantities can be a powerful way to promote an understanding of rates of change (Slavit, 1997; Smith & Confrey, 1994).

Castillo-Garsow (2012) describes covariation as the imagining of two quantities changing together; students imagine how one variable changes while imagining changes in the other. Relying on situations that involve quantities that students can manipulate and investigate can foster their abilities to reason flexibly about dynamically changing events (Carlson & Oehrtman, 2005). An approach that leverages covarying quantities may be especially useful in helping students understand exponential growth, as this view is strongly connected to how students think about contexts involving multiplicative relationships (Davis, 2009).

Hypothetical Learning Trajectories

The notion of a *hypothetical learning trajectory* has different meanings among mathematics education researchers. Under Simon's (1995) original description, a hypothetical learning trajectory consists of "the learning goal, the learning activities, and the thinking and learning in which students might engage" (p. 133). Clements and Samara (2004) elaborate on this definition, describing a learning trajectory as a description of children's thinking and learning in a specific mathematical domain connected to a conjectured route through a set of tasks designed to support their movement through the progression of levels of thinking. This paper makes use of a hypothetical learning trajectory for exponential functions (reported elsewhere in Authors, 2013) that is an empirically-supported model of the students' initial concepts and an account of how they changed over time (Confrey et al., 2009). Rather than reporting the trajectory itself, we focus on two conceptual paths represented in the trajectory: the covariation view and the correspondence view. Each path is exemplified through two students' work as they progressed through the teaching experiment.

Methods

The study was situated at a public middle school and consisted of a 12-day teaching experiment with 3 eighth-grade students (ages 13-14) in which the first author was the teacher-researcher. All students were female. The purpose of the teaching experiment was to support students' reasoning about exponential growth through exploring continuously covarying quantities. The sessions focused on the relationship between height and time for an exponentially growing plant called the Jactus; students were able to manipulate the plant's height over time using an interactive computer program called Geogebra. Although this scenario is not realistic,

the context is realizable (Gravemeijer, 1994) in that students could imagine, visualize, and mathematize the relevant quantities. All sessions were videotaped and transcribed.

We assumed that any understanding students might have about exponentiation before entering a teaching experiment would be dependent on an image of repeated multiplication. Building on that conception, our primary goal of instruction was to foster students' understanding of the following set of concepts for an exponential function $y = a \cdot b^x$:

1. The period of time x for the y-value to increase by the growth factor b is constant, regardless of the value of a or b.
2. There is a constant ratio change in y-values for each constant additive change in corresponding x-values.
3. The ratio of the change in y, which can be expressed as $\frac{y_2}{y_1} = b^{x_2 - x_1}$, is always the same for any same Δx and the value of $f(x + \Delta x) / f(x)$ is dependent on Δx.

Data analysis relied on retrospective analysis techniques (Simon et. al, 2010) to characterize students' changing conceptions throughout the course of the teaching experiment. Project team members developed preliminary codes for concepts on the trajectory based on students' talk, gestures, actions, and task responses as evidence of understanding at different stages. The first round of analysis yielded an initial set of codes, which then guided subsequent rounds of analysis in which the project team met as a group to refine and adjust the codes in relationship to one another; this iterative process continued until no new codes emerged. Once coding was complete we chose 20% of the data corpus for independent coding, which yielded an inter-rater reliability rate of 92%. For the purposes of this report, we focus on two students, Uditi and Jill, as their work provided a way to contrast the influence of a correspondence view versus a coordination view on subsequent concept development.

Results

The progression of the students' understanding of exponential growth occurred in three major stages, which we call *pre-functional reasoning*, *covariation reasoning*, and *correspondence reasoning*. The learning trajectory is depicted visually in Figure 1 for brevity's sake (for a complete report of all of the codes, associated tasks, and data examples see Authors, 2013.) Although pre-functional reasoning preceded the development of the covariation and correspondence views, the latter two ways of thinking did not occur in a sequential nature. While all of the students first developed an early, rudimentary coordination between height and time, they then diverged, some focusing on a more sophisticated covariation perspective, some gravitating towards a correspondence view, and others simultaneously developing both. An emergent goal of the teaching experiment was to support students shifting flexibly between these perspectives as needed.

In the following sections we report on two students, Jill and Uditi, as a way to exemplify a focus on correspondence versus a focus on covariation. All of the students readily identified repeated multiplication as the mechanism determining how the Jactus grew, but did not initially connect repeated multiplication in height to the unit of time. In an attempt to encourage coordination of the plant's height with the number of weeks it had been growing, the teacher-researcher introduced a task requiring students to draw the plant's height after 1 week and after 3 weeks if it doubled every week. For example, Jill's drawing indicated the beginning of her coordination of two quantities; both are present in her picture (Figure 2), and Jill explained that the plant's height for Week 4 would be "double the last week; like Week 4 would be 16 inches."

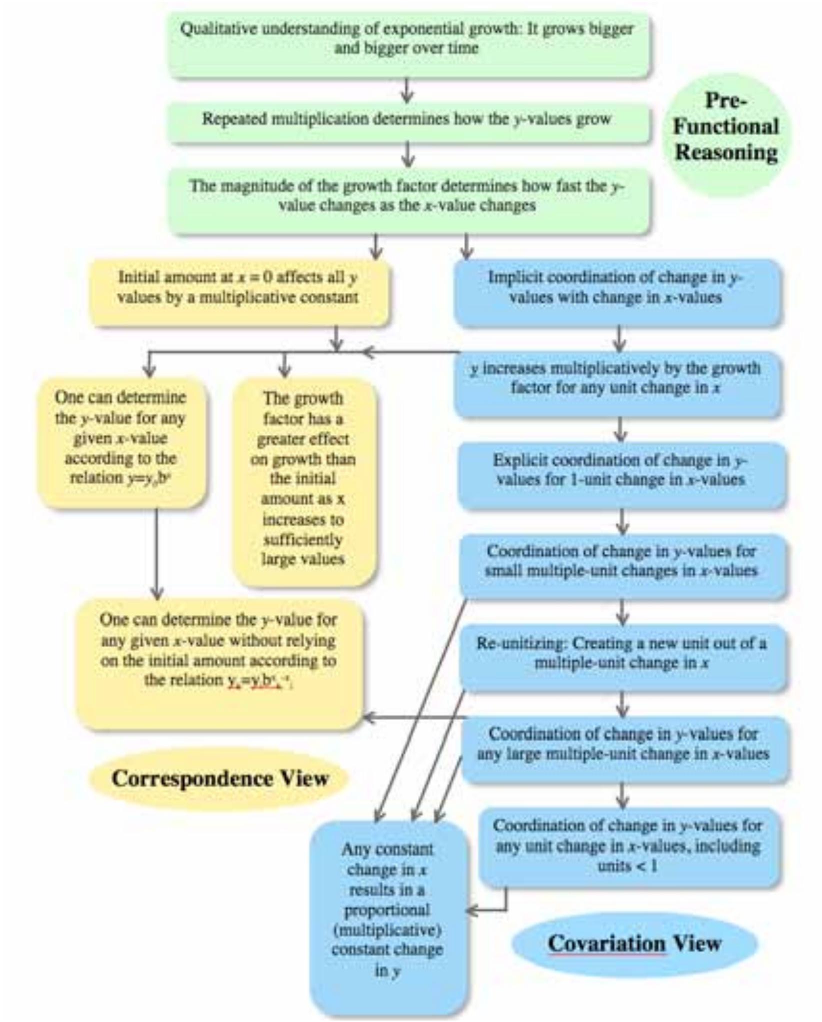

Figure 1: Graphical Representation of Exponential Functions Trajectory

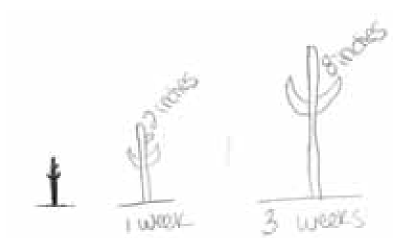

Figure 2: Jill's Drawing of the Growing Jactus

Jill: A Focus on Correspondence

Once Jill determined that the growth factor represented the multiplicative change in height per week, she shifted to a reliance on expressing this relationship algebraically. Jill first developed an algebraic relationship when provided with a data table in which she had to

determine missing height values (Figure 3):

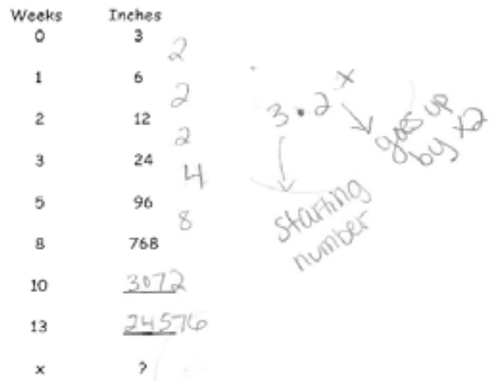

Figure 3: Jill's Strategy for Determining Missing Values in a Data Table

Jill appeared to determine the expression 3•2^x by guessing and checking to find the value of 3. She explained, "You times this number by 2 [justifying 2^x], and then I don't know why the 3 works." Through comparing different doubling plants with various starting heights, Jill began to develop an understanding that in order to determine the correct height at a given week x, she had to multiply 2^x by the initial height, which she called the "starting number": "Well, the starting number of the week 0 is 3, and then do 2 to the x because it's increasing by times 2 each week." In this manner Jill developed a conception of the equation y = ab^x as the "starting number" times "how much it goes up by", where "goes up by" refers to multiplicative growth.

Jill's understanding of the role of the initial height was as the value from which one begins the repeated multiplication process. Once Jill could reliably produce a relation between height and time, she made use of this correspondence rule to determine the growth factor. For instance, when Jill encountered a scenario with only three data points: (0; 1), (20; 1,048,576), and (25; 33,554,432), she explained, "I knew that it would be 1 times something to the x power so I started with 5 [for the missing growth factor] and that was just way too big, and so then I did 3 and it didn't work still, so I did 2 and then it worked and then I plugged in 20 [to check her answer]. So I did 1 times 2 to the 20th power and I got that [pointing to 1,048,576]." Jill's reliance on the correspondence rule shifted her attention to guess-and-check methods to find the missing values that filled in the "slots" in y = ab^x. Although this method is cumbersome, it allows one to avoid taking a ratio to determine the growth factor (for instance, determining the growth factor by taking the ratio of 33,554,432 to 1,048,576, which is 32, and solving the equation x^5 = 32.)

Jill's understanding of the correspondence rule was powerful in that it enabled her to determine missing values; however, it also constrained her thinking. For instance, Jill had to rely on the development of an equation in order to convince herself of the correctness of a growth factor, even when it would be easier to do so by more direct methods. Given three data points for a plant with an unknown growth factor [(8; 19,660.8), (15; 322,122,547.2), and (18; 20,615,843,020.8)], Jill took the plant's height at 8 weeks and multiplied it by different growth factors seven times until she hit upon the correct height value at 15 weeks. Although Jill determined the growth factor was 4 in this manner, she was not convinced of its correctness absent a correspondence rule. Jill therefore divided 19,660.8 by 4 eight times in order to determine the initial height of 0.3 inches. It was only when Jill wrote the equation 0.3 × 4^x that

she could check data points and gain confidence that the growth factor was indeed 4.

The correspondence perspective was so prevalent for Jill that she typically thought in terms of static height and time values rather than imagining how the plant could grow over time; this may be why Jill was unconvinced of her answer of 4 in the problem above. In another example, given a plant that grew 8 times as tall every three weeks, Jill was unable to determine, in absence of an equation, how the plant grew each week. Jill created a sample table of values depicting the plant’s height as 1 inch at 0 weeks, 2 inches at 1 week, 4 inches at 2 weeks, and 8 inches at 3 weeks. Despite the creation of this table, Jill was at a loss to determine the plant’s growth factor, explaining, “I tried to divide 8 by 3 but that didn’t really do anything.” Jill’s restriction to the correspondence view may have hampered her ability to see the growth factor; she may have viewed each entry in the table, such as (1,2), as a static height value, e.g. 2 inches tall at 1 week. A covariation perspective, in contrast, could enable one to also view the point (1, 2) in relationship to the prior point, (0, 1), and see that the plant has doubled in height from 1 inch to 2 inches in the span of 1 week.

Uditi: A Focus on Covariation

Like Jill, Uditi was able to describe the plant’s growth in Figure 2 in a covariational manner: she explained, “In one week it’s going to be 1 inch and in 2 weeks it’s going to be 2 inches, then in 3 weeks it’s going to be 4 and in 4 weeks it’s going to be 8.” When Uditi examined tables of data with jumps in weeks, she initially had to imagine the missing weeks in place. For instance, for Figure 4, Uditi imagined the missing Week 11 in the table: “For the 12 weeks I did times 4 for the answer [to week 11] then I did times 4 for that [to get the height at week 12].” In this manner, Uditi began to coordinate how the height grew with how the weeks grew, keeping track of both and mentally filling in the gaps when necessary.

Eventually Uditi began to formally coordinate the multiplicative growth in inches with the additive growth in weeks. For instance, given a table with a height of 956,593.8 inches at Week 14 and 8,609,344.2 inches at Week 16, Uditi marked a difference of 2 between the successive weeks and a ratio of “×9” between the successive inches. She then described her process: “I divided 8,609,344.2 by 956,593.8 and I got 9. Then I tried to figure out what number times itself = 9 because the difference between 14 and 16 is 2.” In this manner she concluded that the growth factor must be 3, but could not yet generalize her reasoning to any multi-week gap.

Weeks	Inches
0	0.1
2	1.6
5	102.4
9	26,214.4
10	104857.6
12	1677721.6

Figure 4: Uditi’s table of values

In order to encourage this generalization, we introduced tasks with larger gaps between the weeks, such as a plant with an unknown growth factor that is 256 inches at 4 weeks and 1,073,741,824 inches at 15 weeks (Figure 5). The 11-week gap was sufficiently large to discourage Uditi from relying on a mental image of repeated multiplication. Instead, Uditi took the ratio of the height values, which is 4,194,304, and wrote “___^{11} = 4,194,304”. She was then able to determine the missing growth factor that satisfied the equation was 4.

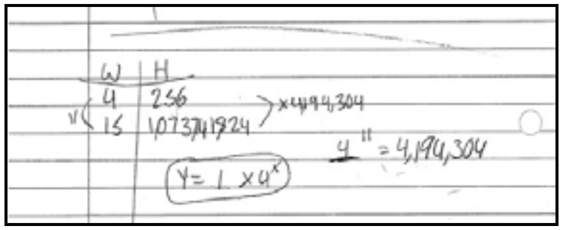

Figure 5: Uditi's strategy for determining the growth factor

In generalizing this approach, Uditi began to coordinate height and time values when $\Delta x < 1$. For instance, given two height values for Week 2.3 and Week 2.4, Uditi could divide them to find the multiplicative ratio, 1.12, and then write "$\_\_\_^{0.1} = 1.12$" in order to determine the growth factor. Tasks asking students to predict how the same plant would grow for different increases in time also fostered the covariation perspective for cases in which $\Delta x < 1$. One such task introduced a plant that tripled each week, asking students to consider how much larger it would grow in 1 day. Uditi responded to the question with "$3^{.14} = 1.17$", explaining, "I divided 1 week into 7 parts, which represents 1 day each and it's .14 of a week." In this manner Uditi was able to make sense of an expression with non-whole number exponent, viewing $3^{.14}$ not just as a static height value, as Jill did, but as an expression of the *growth* in height for 1 day.

Discussion

The expression b^x can both represent a static value (for instance, the height of a plant at time x) and a measure of growth (for instance, how much taller the plant will grow in x amount of time). A correspondence perspective encourages the first conception by emphasizing the direct relationship between height y and time x in the equation $y = ab^x$. Both Jill and Uditi easily understood the expression b^x as a specific height value at a given time. Both students also experienced difficulty in transitioning to an understanding of b^x as a representation of growth in height. We expected this difficulty with Jill, given her focus on correspondence relationships. However, Uditi also found this transition challenging despite her continued emphasis on coordinating multiplicative growth in height with additive growth in time. Uditi's strong early reliance on an image of repeated multiplication may have contributed to this challenge: When conceiving of b^x as a representation of b multiplied by itself x times, it is difficult to think about multiplying a number by itself a fractional amount of times. It is easier to conceive of the x in b^x as a "slot" in which one places the time value, as Jill did.

Uditi's ability to coordinate the ratio of height values with the additive difference in time values played a significant role in supporting the development of algebraic representations. Ultimately, it was easier for Uditi to shift flexibly to a correspondence view, as needed, than it was for Jill to shift to a covariation view. Moreover, Uditi's understanding of the correspondence rules reflected her covariation focus. She understood that when finding the height value at a specific time ($y = ab^{\Delta x}$), she was multiplying the height at week 0 (a) by the multiplicative growth for that time span ($b^{\Delta x}$). In other words, Uditi understood that in order to find the height of the plant, she needed to multiply by the growth factor for every time unit passed. Her reliance on covariation reasoning also enabled her to develop a more sophisticated understanding of the correspondence view in which she no longer needed to start the process from week 0. Instead, she was able to find the height value at a specific time based on the height value at any given week (different than week 0).

In general, a rudimentary level of coordination of growth in height as "doubling each time" with growth in weeks preceded every student's ability to develop correspondence rules of the form $y = f(x)$, which reflects Smith and Confrey's (1994) assertion that students typically approach functional relationships from a covariational perspective first. Our preliminary findings suggest that maintaining an emphasis on covariation may actually assist students' eventual construction and understanding of correspondence rules; therefore, a covariational focus may be the most efficacious in supporting students' understanding of exponential growth.

In this study, we build on previous work on conceptualizations of slope to suggest a framework of slope across the landscape of the mathematics curriculum. Data from multiple studies on students', teachers', and college instructors' conceptualizations of slope are revisited in light of theory on procedural versus conceptual understanding and visual versus analytic interpretations of slope. This synthesis leads to a description of five key slope components. A detailed description of each component is provided and implications for future research are discussed.

Keywords: Algebra and Algebraic Thinking; High School Education; Middle School Education

Introduction

Slope is a key mathematical concept revisited throughout the mathematics curriculum. In addition to being an important mathematical concept of its own right, slope is an important prerequisite concept for advanced mathematical thinking, extending to include the notion of rate of change in precalculus and the concept of derivative in calculus (Carlson, Oehrtman, & Engelke, 2010; Confrey & Smith, 1995; Noble, Nemirovsky, Wright, & Tierney, 2001). Various studies suggest students struggle to understand slope (Barr, 1981; Carlson, Jacobs, Coe, Larsen, & Hsu, 2002; Lobato & Thanheiser, 2002; Orton, 1984; Stump, 2001b; Teuscher & Reys, 2010; Thompson, 1994). In particular, research shows that students' knowledge of slope does not transfer between problem types (e.g., qualitative versus quantitative and mathematical versus real world settings) and that students do not relate the concepts of slope and rate of change (Hattikudur et. al., 2011; Stump, 2001b; Lobato & Siebert, 2002; Lobato & Thanheiser, 2002; Teuscher & Reys, 2010). Students' difficulties connecting notions of slope are understandable in light of the variety of conceptualizations emphasized in the mathematics curriculum. Moore-Russo and colleagues (Moore-Russo, Conner, & Rugg, 2011; Mudaly & Moore-Russo, 2011; Stanton & Moore-Russo, 2012) have suggested eleven conceptualizations of slope, outlined in Table 1, based on their own research and the earlier work of Sheryl Stump (1999, 2001a, 2001b).

Table 1: Conceptualizations of Slope

Category	Slope as …
Geometric Ratio (G)	Rise over run of a graph of a line; ratio of vertical displacement to horizontal displacement of a line's graph
Algebraic Ratio (A)	Change in y over change in x; ratio with algebraic expressions (often seen as either $\Delta y/\Delta x$ or $(y_2 - y_1)/(x_2 - x_1)$)
Physical Property (P)	Property of line often described using expressions like grade, incline, pitch, steepness, slant, tilt, and "how high a line goes up"
Functional Property (F)	(Constant) rate of change between variables; sometimes seen in responses involving related rates
Parametric Coefficient (PC)	The variable *m* (or its numeric value) found in $y=mx+b$ and $(y_2 - y_1)=m(x_2 - x_1)$
Trigonometric	Property related to the angle a line makes with a horizontal line; tangent of a

Conception (T)	line's angle of inclination/decline; direction component of a vector
Calculus Conception (C)	Limit; derivative; a measure of instantaneous rate of change for any (even nonlinear) functions; tangent line to a curve at a point
Real World Situation (R)	Static, physical or dynamic, functional situation (e.g., wheelchair ramp, distance versus time)
Determining Property (D)	Property that determines if lines are parallel or perpendicular; property can determine a line if a point on the line is also given
Behavior Indicator (B)	Property that indicates increasing/decreasing/horizontal trends of line or amount of increase or decrease; if nonzero, indicates intersection with x-axis
Linear Constant (L)	Constant property independent of representation; unaffected by translation of a line; reference to what makes a line "straight" or the "straightness" of a line

These 11 conceptualizations point to the diversity and complexity of slope in the mathematics curriculum. While past research has investigated the prevalence of each of these conceptualizations among individuals who have completed their K-12 education (Nagle, Moore-Russo, Viglietti, & Martin, *in press*; Moore-Russo, Conner, & Rugg, 2011; Mudaly & Moore-Russo, 2011; Stanton & Moore-Russo, 2012), the focus so far has been an isolated description of the conceptualizations without consideration of how they may fit together to form an individual's network of slope conceptions. In the theoretical contribution provided in this article, we reanalyze the 11 conceptualizations in light of one another and research on understanding. In particular, we combine research on procedural versus conceptual understanding with research on visual and analytic interpretations of slope to draw new connections between the conceptualizations. A review of the relevant research is followed by an application of these ideas to the 11 conceptualizations, resulting in a description of a slope conceptualization network with five underlying components.

Procedural versus Conceptual Knowledge

Since Skemp (1967) first described two distinct bodies of mathematics, termed relational and instrumental, considerable research has focused on what is better known now as procedural versus conceptual understanding. Hiebert and Lefevre (1989) describe procedural knowledge as knowing "how to" and conceptual knowledge as knowing "why". More recently, procedural knowledge was described as knowledge of rules and processes linked to specific problems while conceptual knowledge was said to involve a more flexible understanding of governing rules that can be transferred to various problems and situations (Rittle-Johnson, Siegler, & Alibali, 2001). While researchers have taken different stances on the relationship between these two types of understanding and the appropriate developmental sequence (e.g., conceptual then procedural, procedural then conceptual, or simultaneous development of the two), there seems to be consensus that both play an important role in a student's knowledge of mathematics (Geary, 1994; Halford, 1993; Hiebert & Wearne, 1996; Rittle-Johnson & Alibali, 1999).

Findings suggest many students hold only procedural knowledge of the algorithms and interpretations of slope in specific situations, such as rote application of "change in y over change in x" or "rise over run" to find the slope of a line given two points through which it passes. Although students might be able to identify pairs of lines as parallel or perpendicular based on the coefficients of the x-terms in algebraic representations of the form $y=mx+b$, they often do not understand how to use slope to determine the behavior of a linear graph or the

relationship between nonparallel and nonperpendicular lines. Reiken (2008) described students' understanding of slope as procedural and linked this procedural knowledge to students' view of slope as a number in five contexts: number from formula, number from counting, number in front of x, number as relator, and number as rate of change. While the number as relator (relating x and y) and number as rate of change conceptualizations may suggest some conceptual understanding, the remaining interpretations of slope as a number are procedural (Reiken 2008).

Visual Versus Analytic Interpretations of Slope

Students' strategies for solving mathematical tasks are also of interest to researchers. Lowrie and Clements (2001) distinguished between visual and non-visual (verbal/analytic) approaches to mathematical tasks, and described students' transition to more non-visual emphases throughout a school year. Zaslavsky, Sela, and Leron (2002) described analytic and visual interpretations of slope. Analytic interpretations emphasize slope as a "property of the function" that "does not depend on the function's representation" (Zaslavsky et al., p. 122). Notions of derivatives, difference quotients, and the coefficient m were described as analytic interpretations due to their functional emphasis. By contrast, the visual perspective treats slope as a "property of a line" (p. 122), i.e., as the angle formed between the horizontal axis and the line or as the ratio of the vertical change to the horizontal change (Zaslavsky et al., 2002). This study showed the cognitive conflict that arose in the minds of mathematicians who were asked to find the slope of two lines, one of which was represented on a non-homogenous coordinate system (different scales on the horizontal and vertical axes). Using an analytic perspective, the slope of the lines were equal (m=1). However, a visual perspective focused participants' attention on the angles of inclination formed between the lines and the horizontal axes; angles that appeared to have different measures under the two scaling systems. As a result, the authors argue that an analytic perspective is superior to a visual perspective since it holds under both homogenous and non-homogenous coordinate systems.

Combining Theories: A Slope Conceptualization Network

The theory proposed in this study builds on: (a) previous research related to slope; (b) general theories related to understanding; and (c) data collected for slope research studies conducted from 2007 to 2012. The data referenced included mathematics standards documents as well as observations of and written artifacts collected from a variety of individuals who should have already experienced K-12 instruction in slope, including: practicing middle and high school mathematics teachers; high school graduates enrolled in introductory college calculus courses; college graduates with Bachelor's degrees in mathematics, engineering, childhood education, or mathematics education enrolled in graduate teacher education courses; individuals with Master's degrees in either mathematics or mathematics education enrolled in mathematics education doctoral programs; and post-secondary mathematics instructors. These data were used to revisit examples of the 11 conceptualizations in light of: (a) procedural versus conceptual understanding and (b) analytic versus visual interpretations. The original 11 conceptualizations were scrutinized, with particular attention to their connections. The results of this analysis led to the collapsing of some previously distinct conceptualizations. As a result, the researchers constructed a 2x2 matrix indicating procedural and analytic, procedural and visual, conceptual and analytic, and conceptual and visual dimensions for each identified component of slope. A more detailed description of the identified slope components is in the next section.

Components of the Slope Conceptualization Network

When distinctions were made in terms of procedural versus conceptual understanding and visual versus analytic interpretations, connections and relationships between the previously distinct conceptualizations became apparent. Under this lens, five key slope components emerged: (1) constant ratio, (2) determining property, (3) behavior indicator, (4) trigonometry, and (5) calculus. In addition, real world situations were determined to be possible with each of the five components. A description of the four dimensions associated with each slope component, including relationships to the original 11 conceptualizations, follows.

Constant ratio. Table 2 outlines the constant ratio component. Previously distinct algebraic ratio and geometric ratio conceptualizations merge when visual and analytic interpretations of ratio are considered. A student with a visual approach to slope as a ratio might interpret slope as the ratio of rise over run or the vertical change divided by the horizontal change of two points on a linear graph. A more conceptual, but still visual interpretation would include validating the ratio using the notion of triangle similarity to recognize the constancy of the rise/run ratio. An analytic approach to slope as a ratio involves defining slope as the change in *y* values over the change in *x* values. At the conceptual level, the analytic ratio component recognizes slope as a constant rate of change between two covarying quantities. In addition to combining algebraic and geometric ratios via analytic versus visual distinctions, two other important conceptualizations were absorbed into the constant ratio component by consideration of the conceptual versus procedural approach. Notice that the conceptual level of slope as a ratio includes recognizing slope as a constant ratio for linear functions. In other words, conceptual understanding of slope as a ratio requires recognition that this ratio is independent of the particular location on the graph or input/output pairs that are chosen. Thus, the linear constant conceptualization (see Table 1) was absorbed at the conceptual level of the new constant ratio component. Likewise, a conceptual and analytic understanding of slope as a constant ratio involves recognizing slope as a constant rate of change of two covarying quantities, previously known as functional property. Four previously distinct conceptualizations fit under one umbrella when the procedural versus conceptual emphasis and visual versus analytic interpretations are considered. Note that previous conceptualizations are listed in Table 2 using square brackets.

Table 2: Examples of Slope as a Constant Ratio

	Procedural Emphasis	Conceptual Emphasis
Visual Approach	$R_{v,p}$: rise/run or vertical change/horizontal change [previously geometry ratio]	$R_{v,c}$: similarity of slope triangles yields a constant ratio of rise/run regardless of the position on the graph [previously linear constant]
Analytic Approach	$R_{a,p}$: change in *y* over change in *x*; (y_2-y_1/x_2-x_1) [previously algebraic ratio]	$R_{a,c}$: constant rate of change between two covarying quantities; an equivalence class of ratios and hence a function [previously functional property]

Behavior indicator. The behavior indicator component, outlined in Table 3, relates slope to the increasing, decreasing, or constant behavior of a linear graph (visual approach) or function (analytic approach). Under the analytic approach, students first recognize slope as *m* in the equation of a linear function and then interpret the sign of *m* to indicate the function behavior. This recognition of slope as *m* was previously classified as the parametric coefficient

conceptualization. To move to conceptual understanding of slope as a behavior indicator, students must first be able to interpret slope as a ratio. For a visual approach, students can link the increasing or decreasing behavior of a linear graph to positive or negative values of rise and run, which then leads to a positive or negative ratio of rise/run. In the analytic approach, students use the definition of an increasing or decreasing function to determine the sign of the change in *y*/change in *x* ratio. The constant ratio component appears foundational to a conceptual understanding of slope as a behavior indicator.

Table 3: Examples of Slope as a Behavior Indicator

	Procedural Emphasis	Conceptual Emphasis
Visual Approach	$B_{v,p}$: increasing lines have positive slope; decreasing lines have negative slope; horizontal lines have zero slope	$B_{v,c}$: positive rise corresponds to positive run for an increasing line, yielding a positive slope. For a decreasing line, a negative rise corresponds to a positive run, yielding a negative slope. A horizontal line has zero rise for any run, yielding a zero slope.
Analytic Approach	$B_{a,p}$: value of m in the equation for a linear function (e.g., in $y=mx+b$) indicates whether f is an increasing ($m>0$), decreasing ($m<0$), or constant ($m=0$) linear function [previously parametric coefficient]	$B_{a,c}$: application of the definition of increasing/decreasing/constant functions to explain positive/negative/zero slope, respectively (e.g., f is increasing means that $f(x_1)<f(x_2)$ if $x_1<x_2$, so $[f(x_2)-f(x_1)]/(x_2-x_1)>0$)

Determining property. Table 4 shows that the determining property component involves recognizing that slope can: (a) determine the relationship between lines (e.g., parallel) and (b) indicate that a point and slope determine a unique line. While a procedural emphasis requires that students recognize these relationships, a conceptual emphasis includes understanding the underlying features of the linear graphs or functions that yield these relationships.

Table 4: Examples of Slope as a Determining Property

	Procedural Emphasis	Conceptual Emphasis
Visual Approach	$D_{v,p}$: parallel, coplanar lines have the same slope; perpendicular, coplanar lines (lines that intersect at right angles) have negative reciprocal slopes; slope and a point determine a unique line	$D_{v,c}$: parallel lines have the same vertical change for a set horizontal change (otherwise they would intersect); may be seen in terms of congruent slope triangles
Analytic Approach	$D_{a,p}$: ratio (y_2-y_1/x_2-x_1) is equivalent for parallel lines and results in negative reciprocals for perpendicular lines; slope and a point determine a unique linear equation	$D_{a,c}$: parallel lines have equivalent differences in y values for a set difference in x values, yielding equivalent slope ratios

Trigonometry. The trigonometric component of slope is described in Table 5. Once again, distinguishing between visual and analytic interpretations of slope allowed previously distinct slope conceptualizations to be combined under one category. A focus on steepness, which was previously identified as a physical property conceptualization, can be seen as the manifestation of a visual approach of the trigonometric component. Procedurally, the focus is on determining the angle of inclination, whereas a conceptual focus includes viewing the ratio of rise over run in terms of the opposite and adjacent sides of the right triangle formed by the line and the horizontal. The analytic approach to slope in terms of the trigonometry component involves the procedure of calculating $\tan\theta$. At the conceptual level, a student can relate the angle of inclination to the ratio (y_2-y_1/x_2-x_1), also known as $\tan\theta$.

Table 5: Examples of Slope as a Trigonometric Conception

	Procedural Emphasis	Conceptual Emphasis
Visual Approach	$T_{v,p}$: steepness of a line; slope as the angle of inclination of the line with a horizontal; as a line is rotated about a point, the slope changes [previously physical property]	$T_{v,c}$: the angle of inclination determines the rise/run; a steeper line has a greater rise per given run than a less steep line
Analytic Approach	$T_{a,p}$: slope is calculated as $\tan\theta$, where θ is the angle formed by the graph of the linear equation and an intersecting horizontal line	$T_{a,c}$: the angle of inclination determines the ratio of (y_2-y_1/x_2-x_1), which is equivalent to $\tan\theta$

Calculus. The calculus component, outlined in Table 6, involves interpreting slope of a function at a point. Visually, this is done via the slope of the tangent line to the point, with a conceptual emphasis on using secant line approximations to find the slope. Analytically, the slope is found via the derivative function (either via the limit definition or the various shortcuts for finding the derivative). A conceptual emphasis involves understanding the limit definition as describing the average rate of change over increasingly small intervals. Since the visual approach relies on first understanding slope of a line using the rise/run ratio and the analytic approach relies on first understanding slope of a linear function using the change in *y*/change in *x* ratio, the calculus component of slope appears to be closely linked to the ratio component.

Table 6: Examples of Slope in Calculus

	Procedural Emphasis	Conceptual Emphasis
Visual Approach	$C_{v,p}$: slope of a curve at a point is the slope of the tangent line to the curve at a given point	$C_{v,c}$: visual interpretation of secant lines approaching tangent line to understand slope of a curve at a point as the slope of the tangent line at the point
Analytic Approach	$C_{a,p}$: derivative *f'* is used to calculate slope of the function *f* at a particular point	$C_{a,c}$: interpreting $f'(x) = \lim_{\Delta x \to 0} \frac{f(x+\Delta x)-f(x)}{\Delta x}$ as the average rate of change over increasingly small intervals

Real world situations and parametric coefficient. One of the original 11 conceptualizations does not appear above. Real world situations can be incorporated with any one (or any combination) of the outlined slope components. For instance, references to the pitch of a roof would incorporate real world situations into the trigonometry component to determine the steepness of the roof (possibly using the angle formed between the roof line and the ceiling of house's interior), while references to speed as the rate of change between distance and time would incorporate real world situations with the constant ratio component to interpret speed as a ratio describing a relationship between covarying distance and time quantities. Table 7 outlines the components of the slope network as they relate to the original 11 conceptualizations.

Table 7: Revised Slope Network Components and Corresponding Conceptualizations

</table>

Discussion and Conclusion

The above analysis merges past research on students' understanding of slope to provide a more connected understanding of the components of an individual's network of slope concepts. In particular, the analysis suggests understanding slope can be viewed in light of five components, each with four subcomponents defined by the conceptual versus procedural understanding and analytic versus visual interpretations. While it has been argued in the past that students must build a particular type of understanding of slope (e.g., conceptual or analytic), the network interpretation of slope highlights the importance of procedural and conceptual understanding, as well as visual and analytic interpretations of slope. While Zaslavsky and colleagues (2002) suggested that a visual perspective of slope might be limiting, the network suggests that visual interpretations are an important part of an individual's network of slope components. We would argue that limitations stem from a lack of connections between the various components and subcomponents of slope. Not only should instruction build each of the five slope components, but explicit attention should be given to building connections between

the subcomponents. This means that students must have an opportunity to build and connect slope representations that are analytic, visual, procedural, and conceptual.

A wealth of research supports that slope is a critical topic and that students struggle to build a strong understanding of this important topic. We have contributed to the theory for how slope is understood by synthesizing past research to describe a network of slope components and subcomponents that together build a strong and diverse view of slope. This theory can strengthen future research on slope by tying together the important aspects of understanding slope under one model.

AGENCY-AS-INFERENCE: TWO SIDES OF THE SAME EPISTEMIC COIN

José F. Gutiérrez
University of California at Berkeley
josefrancisco@berkeley.edu

This paper attempts to synthesize theory of knowledge objectification (Radford, 2003) with equity research on mathematics education. I suggest mathematical inference as a promising locus for investigating the types of epistemic agency that equity-driven scholars have deemed as vital for student identity and, in turn, participation and learning. I conceptualize students' appropriation of semiotic-cultural artifacts (e.g., algebraic symbols) to objectify their pre- symbolic inferences as conditional on their agency to gradually construct personal meaning for these artifacts. I support this claim with preliminary empirical analysis of a Grade 9 student's participation during an algebraic pattern-finding task.

Keywords: Algebra and Algebraic Thinking, Classroom Discourse, Equity and Diversity

Introduction & Objectives

In this study I suggest the phenomenon of mathematical inference, which is central to cognitivist analyses of learning, as a promising locus for investigating the types of epistemic agency that equity-driven scholars have repeatedly demonstrated are necessary for the development of constructive mathematical identities (Boaler & Greeno, 2000; Nasir & Hand, 2006). I consider epistemic agency and mathematical inference as 'two sides of the same coin'.

The crux of my theoretical argument is based on Luis Radford's (2003) theory of *knowledge objectification* and, in particular, his *semiotic–cultural framework* for the study of students' algebraic reasoning (see below). Through the lens of agency-as-inference, my broader theoretical agenda is to synthesize Radford's approach with equity-oriented perspectives that account for issues related to students' mathematical identity. To support this claim, I have proposed elsewhere a qualification to theory of knowledge objectification that, in contrast to its extant formulation, does not assume classroom homogeneity in opportunities to appropriate mathematical semiotic artifacts (Gutiérrez, 2013). To demonstrate the empirical viability of this emerging approach, this study focuses on algebraic generalization as a specific genre of mathematical inference and applies Radford's framework to video data of a Grade 9 student's participation during an algebraic pattern-finding task.

Theoretical Background - Overview of the Semiotic–Cultural Approach

Luis Radford's (2003, 2008) semiotic–cultural approach was developed in the context of algebraic generalization activity (see Figure 1, below). Specifically, mathematics learning is conceptualized as constructing personal meaning for canonical semiotic artifacts (e.g., algebraic symbols such as the variable "x"). Through consolidation and iteration of these constructions, students appropriate the mathematical semiotic artifacts and, reciprocally, build personal meaning for mathematical content as well as fluency with the disciplinary procedures.

Radford's approach takes into account a vast arsenal of personal and interpersonal resources that students bring to bear in solving mathematical situations, including linguistic devices and mathematical tools. A key construct in Radford's framework is *knowledge objectification*, which is defined as the process of making the objects of knowledge apparent (Radford, 2003).For

example, a mathematics learner, in an attempt to convey a certain aspect of a concrete object, such as its shape or size, will make recourse to a variety of semiotic artifacts such as mathematical symbols and inscriptions, words, gestures, calculators, and so forth. In patterning activity, however, some of the objects of knowledge are general and therefore "cannot be fully exhibited in the concrete world" (Radford, 2008, p. 87). In order to instantiate these ephemeral objects, students must resort instead to personally and culturally available forms such as linguistic, diagrammatic, symbolic, and substantive artifacts as well as the body, which Radford (2003) collectively terms *semiotic means of objectification* (see also Abrahamson, 2009).

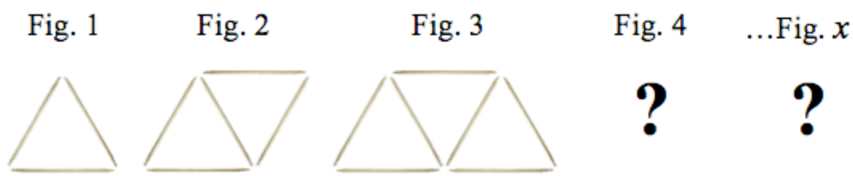

Figure 1: "Toothpicks"— a paradigmatic algebra generalization problem. The task objective is to express U_x the total number of toothpicks in the x^{th} figural extension (i.e., "Fig. x" consists of $2x+1$ toothpicks).

The power of the semiotic–cultural approach is that critical steps within individual learning trajectories can be explained by noting subtle shifts in the subjective function and status of the semiotic artifacts. In particular, mathematics learning in the context of algebraic generalizations can be monitored as subjective transitions along a desired chain of signification, from *factual*, to *contextual*, to *symbolic modes* of reasoning (Gutiérrez, 2010; Radford, 2003).

Factual	Contextual	Symbolic
• Objects and operations are bound to concrete level • E.g., Student utterance: "1 plus 2, 2 plus 3, 3 plus 4…"	• Objects and operations are abstracted and generalized • E.g., "The *figure* plus the *next figure*."	• Objects and operations are expressed through formal symbolism • E.g., "x + (x+1)"

Figure 2: "F-C-S framework applied to the "Toothpicks" problem; see Figure 1, above.

From this perspective, conceptual understanding is viewed as the capacity to flexibly shift across the three semiotic modes, which consequently requires that students assume agency in making these shifts so as to carefully and incrementally construct personal meaning for conventional semiotic artifacts (e.g., the variable "x"). Students' personal acts of generalization are a specific type of mathematical inference; and transitions from one semiotic mode to the next mark *both* conceptual understanding and epistemic agency. That is, agency and conceptual understanding can be co-investigated by interrogating the process and content of students' mathematical inferences (generalizations) within and across the three semiotic modes.

Agency-As-Inference in Algebraic Patterning Activity

I present an example of a classroom problem-solving activity involving the "Toothpicks" problem to illustrate the construct of agency-as-inference. The excerpts that make up this classroom scenario are drawn from my research on equitable participatory design. The specific intervention wherein the data for this study were collected was conducted in a high school

mathematics program for academically at-risk youth. The intervention was intended to implement a classroom participation structure that would facilitate a particular desirable interaction among students and ultimately give rise to authentic engagement and deep learning.

I focus on student Magdalena (Grade 9) and present qualitative data analyses of a series of transcript segments of her contributions to the whole-class discussion. By conducting detailed and sequential analyses of her mathematical behaviors, I aim to elaborate my thesis that a student's mathematical inferences bearing generalization are indicative of epistemic agency.

The transcript segments begin after the teacher, Amil, writes "Fig. 100" on the far right side of the board. Magdalena articulates an arithmetic/recursive strategy in the form Ux+1=Ux+3-1, stating: "if you're adding another triangle, it's another three [toothpicks] but then you subtract one." But she soon realizes the limitations of this strategy for producing figural extensions much further down the line (Fig. 100), because as she states: "you don't know the figure before" (i.e., *U99* is unknown). As a result, she spontaneously proposes the use of a variable "*x*" as a placeholder for a given figure's ordinal position.

Magdalena: You have to do x instead of a number. Because if you use x then it could be any number.

Amil: Ok so you have to use x—we gotta use x. So what is x gonna be?

Magdalena: **X is the amount of triangles**.

Implicit in Magdalena's proposition is the understanding that "*x*" could serve as an indeterminate quantity, thus enabling operation on the figure numbers (ordinal positions) independent of the previous figures in the sequence. Magdalena guides her peers to look for patterned relations with*in* and not just across the figures. So doing, Magdalena leads the class to a closed-explicit solution procedure (U_x=2x+1), first objectified as a contextual generalization and then reformulated as a factual generalization.

Magdalena: I found something. Ok so if you **add the figure number to itself, plus 1**, it will equal the amount of toothpicks.

Amil: Ok figure number to itself. So [indicates Fig. 1] 1 plus 1, plus 1 more? Equals 3. So [indicates Fig. 2], 2 plus 2…

Magdalena: 4, plus 1 is 5.

Amil: …plus 1 equals 5. [Indicates Fig. 3.]

Magdalena: **3 plus 3 is 6, plus 1…7. 4 plus 4…8, plus 1…9. 5 plus 5…10, plus 1…11.**

Amil: Ok how about figure 100? How many [toothpicks] would it have?

Magdalena: **100 plus 100…200, 200 minus—I mean 200 plus 1…201**.

Magdalena's inferential/semiotic trajectory thus far appears to follow the path "S-C-F." That is, Magdalena was operating in the symbolic mode when she proposed the use of the variable "x," which was followed by her objectification of an algebraic generalization in the contextual mode ("add the figure number to itself, plus one"). Amil was able to scaffold her inquiry such that Magdalena went *back* to the factual mode, further grounding her generalizing inferences in actual constituent elements of the source situation (Fig. 1, Fig. 2, Fig. 3, and Fig. 100).

Magdalena further elaborates on her search process and extends her trajectory to "S-C-F-C":

Magdalena: [addressing the class] The thing—see the thing that I did though, I was just looking for things that they all had in common. And **they had the figure number plus another one**.

Ultimately, I diagnose the final "S" of her evolving "S-C-F-C-S" trajectory (see immediately below) as a generalization *to* that mode yet *partially* grounded, because it is Amil and not Magdelena who reformulates her final contextual generalization into symbolic form. I maintain

there was enough conceptual substrate—at the cognitive-semiotic level—for Magdelena to appropriate Amil's reformulation in a way that bore personal meaning.

Amil: "Ok so you said the figure number...1...plus the figure number again, right? What's another way of saying that? Instead of saying the figure number plus the figure number again..."

Magdalena: "I don't know."

Amil: "Ok Uhh let's see. [referring to Figure 2] 2 plus 2 plus 1. What's another way of saying 2 plus 2? Or [indicating Fig. 3] 3 plus 3? [No response from class] How about 2 times the figure number, plus 1? Right?"

Magdalena: "Yeah umm…oh yeah."

Amil: "Ok so that is... [writes "2n+1" on the board] so that's our—" *Magdalena*: "So it could still be—it could still be x! **So it'll be 2 x plus 1**." *Amil*: "Or 2 x plus 1. You can put any letter there."

Magdalena: "Ok."

I conclude that Magdalena's subjective inferences underlying mode-*to*-mode transitions are where, and through which, her epistemic agency is instantiated and achieved (Figure 3).

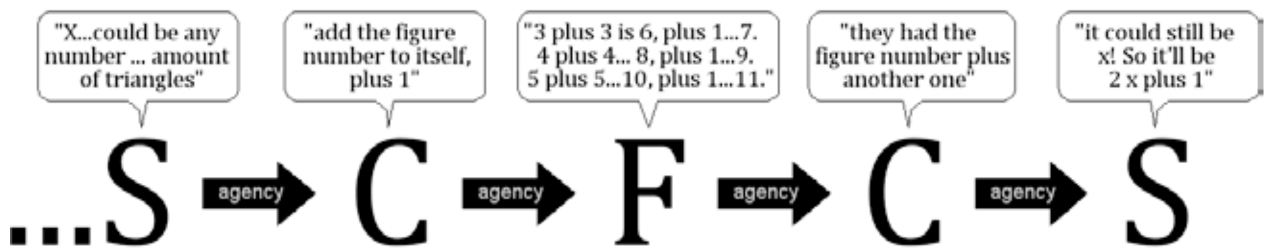

Figure 3: Magdalena's semiotic trajectory. "F," "C," and "S" represent the active semiotic mode of the "text"—the words that are being uttered into the classroom. Whereas semiotic mode is objective and shared in the discursive space, *transitions* between modes are subjective. Arrows "è " represent Magdalena's subjective mode-*to*-mode transitions; for example, "è F" means Magdalena's cognitive-semiotic actions indicate that she indeed generalized *to* the factual mode (Gutiérrez, 2010). It is "in the arrows" where agency-as-inference lives.

Future research will explore the development of agency-as-inference and its impact on students' mathematical identities, specifically for marginalized students whose mathematical understandings are not couched in the mainstream classroom discourse.

Third-grade students are participating in a classroom experiment investigating the impact of instruction derived from a research-based Early Algebra Learning Progression. Students completed a pre-assessment item addressing their abilities to justify a conjecture about the sum of three odd numbers. While they were largely unsuccessful on the assessment, through the course of the classroom intervention students are beginning to develop representation-based arguments and provide generalizations using facts about the sum of even numbers and odd numbers.

Keywords: Algebra and Algebraic Thinking, Reasoning and Proof, Elementary School Education

For many students, algebra continues to be a gatekeeper to future academic and employment opportunities. As a result, reform efforts in recent years (e.g., Common Core State Standards Initiative, 2010) have sought to integrate aspects of algebra into elementary and middle school mathematics curricula.

In response to this call, our project's overarching goal is to examine the effectiveness of a longitudinal grades 3-5 early algebra intervention on children's algebra learning and algebra-readiness for middle school. Our intervention—currently in its first year (i.e., grade 3)—is derived from a research-based Early Algebra Learning Progression [EALP] organized around five "big ideas": 1) Generalized Arithmetic, 2) Equations, Expressions, Equality, and Inequality, 3) Functional Thinking, 4) Proportional Reasoning, and 5) Variable (Blanton, Stephens, Gardiner, Isler, & Knuth, 2013).

We focus in this paper on our findings regarding the development of third-grade students' understanding of generalized arithmetic, particularly in the context of even numbers and odd numbers. We share pre-assessment data and representative excerpts from student work and briefly discuss the classroom intervention we believe is contributing to student learning. Posttests will be administered in May 2013 and results will be included in our presentation.

Theoretical Perspective

According to Kaput (2007), the essence of early algebra includes developing and justifying mathematical generalizations in various ways, and reasoning with those generalizations. Blanton (2010) further states that children's work in generalizing arithmetic relationships can also strengthen their abilities to engage in mathematical reasoning and proof in the elementary grades. Carpenter and Levi (2000) provide evidence that students can develop conjectures, representations, and justifications to support their ideas as early as first grade.

Investigating operations on even numbers and odd numbers has been found to engage students in developing and justifying generalizations (Carpenter, Franke, & Levi, 2003). Russell,

Schifter, and Bastable (2011) observed students using four different approaches to justify a conjecture: accepting the claim on authority, trying it out with examples, applying mathematical reasoning based on a visual representation or story context, and proving using algebraic notation and the laws of arithmetic. They further emphasized that employing visual representations or story contexts in making mathematical arguments—i.e., engaging in "representation-based proof"—is an effective route to establishing general claims in elementary classrooms.

It is already known that young children can engage in mathematical reasoning and learn to use sophisticated arguments to justify conjectures about the sums of even numbers and odd numbers (Ball & Bass, 2003; Blanton, 2008). In this paper, we aim to explore third-grade students' capacity for developing conjectures about these types of arithmetic generalizations, and examine how students who have had a year long focus on early algebra (including generalized arithmetic) justify these conjectures in comparison to students who have had more traditional arithmetic-based experiences.

Method

Participants

Participants included 170 third-grade students from two elementary schools in southeastern Massachusetts. The school district in which these schools reside is largely white (91%) and middle class, with 17% of students qualifying for free or reduced lunch. Six classrooms (all from one school) served as experimental sites and 4 classrooms (all from one school) served as control sites.

Data Collection

A one-hour written assessment addressing the range of "big ideas" present in our EALP was administered to all participants prior to the start of the teaching intervention in September 2012. We focus here on one assessment item (see Figure 1) concerning students' justifications related to the sums of even numbers and odd numbers.

> Brian knows that anytime you add three odd numbers, you will always get an odd number. Explain why this is always true.

Figure 1: The Three Odd Number Sum task

An identical posttest will be administered when the third-grade intervention ends in May 2013. Therefore, in this paper, we share results of only the pretest and classroom observation. Posttest results will be shared during the presentation.

Classroom Intervention

Students in the experimental condition are participating in an EALP-based classroom teaching experiment for approximately one hour each week for the majority of one school year. A member of our research team—a former third-grade teacher—is serving as the teacher during these interventions. A typical one-hour lesson consists of a "jumpstart" at the beginning of class to review previously discussed concepts, followed by group work centered on research-based tasks aligned with our EALP.

Two lessons specifically included tasks concerning the sums of even numbers and odd numbers, though students were engaged in conjecturing and justifying more broadly (e.g., in the context of the fundamental properties such as the commutative property of addition) for several weeks prior to this. An example of a task that was used in the intervention is presented in Figure 2.

Jesse is adding two even numbers. Do you think his answer will be an even number or an odd number? Develop a conjecture to describe what you found. Is your conjecture true for any two even numbers you add together? How do you

Figure 2: The Two Even Number Sum task

Data Analysis

A member of the research team coded all the student responses to the written assessment item. Five categories of student responses emerged from the data: *Empirical argument*, *Even/odd generalization*, *Incorrect counter-example*, *Restatement of the argument*, and *Incomplete even/odd generalization*. A response was coded *Empirical argument* when students concluded that the conjecture is true when they tried it out with examples such as "3 + 5 + 7 = 15." A response was coded *Even/odd generalization* when students developed their argument based on what they knew about even and odd numbers, such as "2 odd numbers equal an even number so add an odd number and it turns odd," that included using the previous generalizations about even numbers and odd numbers to produce a generalization in words, pictures, or symbols. *Incorrect counter-example* was used when students stated that the conjecture was not true, possibly because of misreading the question, and justified it with a counter-example such as "3 + 3 = 6, and 6 is an even number, not odd." *Restatement of the argument* was used when students restated the conjecture given in the task. Lastly, *Incomplete even/odd generalization* was used when students made a general but incomplete argument, often missing the final step.

All other responses were coded as either "no response" if a student left the item blank, or "other" if the student response did not fall into any of these categories and was not frequent enough to constitute its own code.

Results and Discussion

The pretest results showed that 21% of students relied on examples to justify the argument, which were coded as *Empirical argument* as explained above. An example from students' written responses is "3 + 5 + 7 = 15, that's an odd number." In contrast, 5% of students provided a generalization about the sums of odd numbers that was coded as *Even/odd generalization*. For instance, one student explained, "It's always true because when you add 2 odd numbers, it makes an even number but if you add a third one, it will be odd." Four percent of student responses were coded as *Incorrect counterexample*. For instance, a student explained "It is not true because if you add 1 + 3, you get 4 and that is an even number." Three percent of students were found to just restate the argument. For instance, one student said "It is true because if you add 3 odd numbers, it will be an odd number." Two percent of students were found to provide a valid but incomplete argument. For example, one student stated "If you add two odd numbers then you`ll get an even number." The final step of the argument, that an even plus an odd is an odd, was missing. Thirty-four percent of all student responses were coded as "no response," and 31% were coded as "other." An example of an "other" code is "It is true because you`re counting with odd numbers." These responses were not found frequently enough to constitute their own code.

Results of the pre-test suggest—not surprisingly—that students were much more likely to produce an empirical argument than provide a general argument. In fact, many students did not provide a response, which might be interpreted as that a majority of them did not have the cognitive tools for thinking about this type of problem. However, our instructional intervention suggests that students can develop ways of thinking that might support a more formal

understanding of proof. At the beginning of adding even and odd number lessons in our EALP-based classroom intervention, students were asked to explore even and odd numbers using their unifix cubes, and were asked to complete a table indicating the "number of pairs created" and "number of cubes left over" for the numbers they explored. The teacher guided the students throughout this activity by asking questions such as "How many pairs of cubes are in the number 6?", "What do you notice in the table?", "What kinds of numbers have no cubes left over after all pairs are made?" The aim was to have students realize the pattern that even numbers have no cubes left over after all pairs are made, and odd numbers have one cube left over. Then, they were given the task of adding two even numbers (see Figure 2). Students first started checking "cases" to see whether the result was an even or odd number. A student said "I think we should try some math facts, like 2 + 2 is 4 [showing with the cubes], so I think even plus an even will be an even." The teacher asked students to develop a conjecture, and think about whether it would work for *all* numbers. Students developed conjectures such as "when you add an even number plus an even number the sum will be even." When asked whether it always works, some students stated that does because "I tried a bunch of examples and it works for all of them." When the teacher asked them *why* it works, they continued their discussion, working in small groups, and justifying with their cubes. As they described it, "When we add even numbers we don't ever start with any leftovers. Everyone has a pair, so we can add them together and everyone will always have a pair." Students' justifications, including representation-based arguments, helped them generalize for all numbers rather than focus on specific numbers. The class continued to explore the sum of two odd numbers, and the sum of an even and an odd number in the following lesson.

Given the appropriate instruction, we see that third-grade students can be successful in developing conjectures, investigating *why* and generalizing. These skills are at the heart of mathematical reasoning, and were found to be attainable for students participating in an EALP-based classroom intervention.

Endnote

COORDINATING n+1 LEVELS OF UNITS

Anderson Norton
Virginia Tech
norton3@vt.edu

Steven Boyce
Virginia Tech
sboyce@vt.edu

Across multiple mathematical domains, researchers have implicated the critical role of an individual's ability to coordinate units. In this proposal, we describe a theoretically grounded instructional approach for promoting pertinent growth. We present promising results from an implementation of our approach in a ten-week teaching experiment with a sixth-grade student, named Cody. We demonstrate how, over the course of the teaching sessions, Cody progressed from requiring physical activity in order to coordinate two levels of units to being able to coordinate three levels of units (in activity).

Keywords: Number Concepts and Operations, Instructional activities and practices

Significance

Integers, fractions, and algebra present notorious challenges for our students. Recent research on students' ways of operating mathematically indicates a common root cause. Namely, many students lack the ability to coordinate the various levels of units involved in reasoning flexibly within each domain. A growing body of research indicates that the levels of units students coordinate mediate opportunities for learning across several domains (Ellis, 2007; Olive & Çağlayan, 2008; Ulrich, 2012). This introduces a serious problem for mathematics educators because, even by middle school, many students work with only one level of units and few readily work with three levels of units (Norton & Wilkins, 2012).

We address the problem by introducing an instructional approach to promoting growth in the levels of units that students coordinate. The purpose of the underlying study was to test the approach through a teaching experiment with a sixth-grade student. In particular, we tested whether we could provoke reorganization in his ways of operating so that he could assimilate situations involving two-level structures and begin coordinating three levels of units in activity.

Theoretical Framework

Units coordinating refers to the structures and operations students can produce in activity and those students use to assimilate situations involving embedded quantities. Consider the following task: A student is given a short bar, a medium bar, and a long bar and is told that the short bar fits into the medium bar three times and that the medium bar fits into the long bar four times; then the student is asked to determine how many times the small bar fits into the long bar. Table 1 outlines typical responses indicating the number of levels students coordinate.

Table 1: Levels of Units Coordination

	Students' Unit Structures	Students' Reasoning on the Bar Problem
Level 1	Students can take one level of units as given, and may coordinate two levels of units in activity.	Students mentally iterate the short bar, imagining how many times it would fit into the longer bar. This activity might be indicated by head nods or sub-vocal counting.
Level 2	Students can take two levels of units as given, and may coordinate three levels of units in activity.	Students mentally iterate the medium bar four times, with each iteration representing a 3. This activity might be indicated by the student uttering "3, 3, 3, and 3; 12."

Level 3	Students can take three levels of units as given, and can thus flexibly switch between three-level structures.	Students immediately understand that there are four threes in the long bar. This assimilation of the task might be indicated an immediate response of "12", buttressed by an argument that 12 is four 3s.

Our Approach

Starting with a number, say 30, its prime factorization (with multiplicities) determines a maximum number of levels—m+1, where m represents the number of prime factors. For instance, 30=2×3×5 has 3+1=4 possible levels. We can build these four levels in any context that students can assimilate as an embedding structure. For example, we can consider a box of cups, where each cup has a specified number of chips, of a specified value.

Level A: cents
Level B: chips, with relation BA: 2 cents per chip
Level C: cups, with relation CB: 3 chips per cup
Level D: boxes, with relation DC: 5 cups per box

Now we consider all possible permutations of two levels, from among A, B, C, and D. There are 4×3=12 such permutations, and each of them suggests a task. For example, consider DA: "How much is a box worth?" We can also consider permutations of three levels, where the middle level is an intermediate level. Consider ACD: "If you have 12 cents, how many more cups do you need to make a box?" This approach to task design, with the intent of promoting the coordination of higher levels of units, incorporates three principles arising from existing research on students' mathematical ways of operating.

First, if a student has internalized and organized n (1 or 2) levels of units, tasks should challenge the student to coordinate n+1 units in activity (Hackenberg and Lee, 2012). By varying the units students need to coordinate within the same problem setting, our approach provokes students to simultaneously maintain multiple relationships involving n+1 units. Second, media need to provide students with opportunities to physically enact these various coordinations (Clements, 2000). Our approach allows for the use of various manipulatives and contexts, so long as they fit the embedding structure. Finally, students need opportunities to reflect on their activity. Our general task setting is amenable to such reflection because it supports physical activity related to packing and unpacking units. Students can re-present these activities within diagrams and other drawings to illustrate relationships between various units.

Data and Analysis

We conducted a teaching experiment with a sixth-grade student named Cody. During a 15-minute interview with Cody, we determined that he readily engaged in units coordinating tasks but that he operated with only one level of units at a time. This made him an ideal candidate for our study, in which we wanted to engage students in activity that might provoke units coordination with higher levels of units.

Our teaching experiment began on September 13, 2012, during which we affirmed our initial assessment of Cody as a student who had not yet internalized and organized two levels of units. Beginning on September 18, we initiated our approach to promoting that development. Ten more 30-minute teaching sessions followed, charting a progression in Cody's units coordinating activity, and leading up to a key development on November 15.

Session 1: September 18

We used this first session to assess Cody's units coordinating activity within the context of relating cents, chips, cups, and boxes, as described in the approach section. The teacher-researcher began by asking Cody to put three chips in each of five cups, to put these five cups in a box, and to close the box. In the following transcription, "T:" precedes the words [and actions] of the teacher-researcher (first author), and "C:" precedes those of Cody.

T: If a chip is worth two cents, how much money would be in the box?

C: Chips are 2, and there's five. Since there's six in each one, because 2, 4, 6. And there's 5 cups. Six times 5, and it equals 30. [smiles and dances a little]

This approach, of building from the smallest unit, became typical for Cody. He built 2, 4, 6 cents and then considered the value for five of these collections. In a subsequent question, he was asked to determine the number of *chips* in the box, but he did not have an answer. Although the new task would seem no more complicated that the first, chips were a composite unit in this context, and Cody consistently appeared uncomfortable in working with such units. Thus, Cody's actions in this session fit our initial assessment that he could only organize two levels of units in activity, by building up from the smallest unit.

Session 11: November 15

Due to scheduling conflicts, three weeks passed between the tenth teaching session and this one. We engaged Cody in a problem setting involving ten chips in each cup, five cups in each box, and two boxes in a crate. Before the teacher-researcher could begin asking questions, Cody requested a sheet of paper on which he wrote down all of the relations. After Cody quickly answered several two-level questions, the teacher-researcher began the following exchange:

T: If you have 400 chips, how many crates would you have?

C: [stands up and points to the first "crate" and three more imaginary ones] A hundred, 200, 300, 400. Four!

T: Okay. If you had 400 chips, how many boxes would you have?

C: [sweeping his arms across the four (imaginary) crates] Four; two in each one. Eight.

T: Nice! How many cups would you have?

C: [pointing to the first crate and then each of the others, in succession] There's 10, 20, 30, 40! [pulling on the hood of his jacket] I think this is my lucky jacket…. I think this jacket makes me smart.

The session continued with tasks involving three levels of units—the kinds of tasks that had been troublesome for Cody up to this point.

T: If you have 30 chips, how many more cups would you need to make a crate?

C: How much cups… Six, because… Wait, you said 30, so that's three cups. Five plus two, that's seven! Woohoo!

T: If you have five cups, how many more boxes would you need to make a crate?

C: Five cups? Boxes? One.

T: If you have eight cups, how many more chips would you need to make a crate?

C: 20.

If you have one box, how many more chips would you need to make a crate?

C: 50.

If you have one box, how many more cups would you need to make a crate?

C: 5.

T: That *is* your smart jacket.

Conclusions and Implications

At the beginning of the teaching experiment, Cody only assimilated one level of units and had to build higher levels of units through activity, from that first level (and this despite his fluency with multiplication facts and computations). Even when he built two levels of units in activity, he had difficulty in reversing the relationships between the units. Limitations in his ways of operating were especially apparent in responding to questions involving three levels of units, which he could not build even through activity, until the final session.

Session 11 followed a long period of rest, which was preceded by a series of sessions intended to provoke Cody's ways of operating. In such situations, students often have time to subconsciously reorganize their ways of operating, in response to the provocations. Steffe (1991) has attributed this kind of reorganization to a process he calls "metamorphic accommodation." We suggest that Cody's ways of operating underwent a metamorphic accommodation, as indicated by his responses to the three level questions posed in the final session. Leading up to that session, it seems that he had internalized and organized a two-level structure and that he could simultaneously coordinate three levels of units in activity.

If Cody's growth can be attributed to our approach and if its success can be replicated with other students, the implications for middle school mathematics education would be substantial. A growing body of research indicates that units coordination plays a vital role in much of K-12 curriculum (Ellis, 2007; Hackenberg & Lee, 2012; Norton & Wilkins, 2012; Olive & Çağlayan, 2008; Steffe & Olive, 2010; Ulrich, 2012). In particular, students need to coordinate three levels of units in order to meaningfully address much of the middle school curriculum, and with the new *Common Core State Standards* (2010), this demand might very well extend into the upper elementary grades (Norton & Boyce, 2013). Thus, approaches to provoking and supporting students' units coordinating activity require sustained investigation.

FUNCTION KNOWLEDGE OF 12TH GRADE STUDENTS IN THE UNITED STATES

Arnulfo Pérez
Indiana University
perez4@indiana.edu

Peter Kloosterman
Indiana University
klooster@indiana.edu

This study uses items from the 2005 and 2009 NAEP Grade 12 mathematics assessment to describe student performance on function concepts. The conceptual framework for the study integrates several concepts of the function to account for their relevance beyond algebra, including such areas as geometry and statistics. It further provides an overview of nationwide student performance on function items and a comparison between student performance on function items that engage analytic processing of information versus those function items that engage visual processing of information. Item analysis will shed light on relevant challenges that functions pose for students.

Keywords: Algebra and Algebraic Thinking, Curriculum, Assessment and Evaluation

Most research on student understanding of functions has been limited to small studies (Drijvers, Doorman, Boon, Gisbergen, & Gravemeijer, 2007; Vinner & Dreyfus, 1989), and as a consequence we lack a clear sense of student performance on functions at the national level. To address this gap, the present study (still in progress) analyzes nationally representative data from the National Assessment of Educational Progress (NAEP) and thus provides a broader view of U.S. students' mathematical performance on functions.

For the Grade 12 math assessment, NAEP reports overall results to represent nationwide math achievement as well as results broken down by content strand (number and operation; geometry and measurement; algebra; and data analysis, probability, and statistics). It does not, however, break these strands down into further subcategories or provide information about skills or concepts that extend over several content strands. The study identifies those NAEP items related to functions (across several content strands) and analyzes this data to identify what U.S. students know about functions in general as well as how they perform differently on items that elicit a visual or an analytic approach to handling functions.

While NAEP primarily classifies items related to functions as belonging to the algebra strand, the high-school Common Core State Standards for Mathematics (CCSSM) present functions as their own conceptual category. (The other CCSSM categories are number and quantity, algebra, modeling, geometry, and statistics and probability.) This shift in classification highlights the changing thinking about functions, from a view of functions as a subset of algebra to functions as a dynamic concept that intersects with numerous other mathematical ideas, cutting across content traditionally divided into separate courses. For example, functions play a role in statistics (e.g., linear regression), geometry (e.g., area of a square as a function of the length of its side), and in real-world applications (e.g., the modeling of growth, decay, and motion) (Ponte, 2007).

Another important dimension of functions is that they can be represented in a number of ways (e.g., graphical, algebraic, tabular). Research has repeatedly demonstrated that this diversity of representations—and the conceptual complexity of shifting from one form of representation to another—contributes to the challenge students face when handling functions (Carlson & Oehrtman, 2005; Eisenberg, 1991). Despite their cross-content relevance, functions

are typically discussed most explicitly in an algebra context (Doorman & Drijvers, 2011). The result may be that students have a limited concept image of functions; that is, the set of mental representations that they associate with functions does not reflect the breadth of representations they may encounter through their mathematical learning trajectory (Vinner & Dreyfus, 1989).

In addition to providing an overview of nationwide student performance on functions, this study considers how presentation of test items related to functions may affect students' ability to engage with the approaches that are best suited to obtaining a solution. For example, if the most appropriate or accessible approach to a given problem is outside the student's range of experience with functions, they are unlikely to succeed on the item. While NAEP data do not provide access to this level of detail about student thinking, careful attention to overall student performance as well as to item-level characteristics can shed light on the current state of student understanding of functions in the U.S.

Conceptual Framework

The NAEP Grade 12 assessment is based on a conceptual framework that outlines content assessed, sampling characteristics, and the presentation of items, among other features. For the purposes of this study, the NAEP framework is assumed to be adequate in terms of item development, collection, and reporting of data. It is further assumed that the NAEP items used in the study are appropriate measures of students' knowledge of functions. This study defines student understanding of functions as correct responses on function-related items given on the NAEP assessment. The concept of functions is understood as encompassing the idea of input-output assignment (correspondence) as well as the idea of a process of co-variation to arrive at a broader understanding of the function as a dynamic mathematical object that can be presented in different ways (Oehtrman, Carlson, & Thompson, 2008; Ponte, 2007). The distinction between items that appeal primarily to visual or analytic processing draws on research that has demonstrated a gulf between students' visual concept images of functions and their analytic characterizations of functions (Eisenberg, 1991). Thus, the classification of items as "visual" or "analytic" is primarily geared toward anticipating what thinking about functions would most readily be elicited from students in responding.

Method

The study uses 41 function items from the 2005 and 2009 NAEP Grade 12 mathematics assessment, 21 of which are classified as analytic and 20 of which are classified as visual. All items used for the study relate to functions (including function items categorized by NAEP under geometry and statistics). Items are identified as related to functions (a) if the item refers to functions or includes a representation of a function in either the question or the answer choices or (b) if at least one possible approach to solving the problem relies upon knowledge of functions. Next, the items identified as relating to functions are further classified into two categories: those items that engage analytic processing of information (e.g., the problem includes formulas and/or verbal description) versus those items that engage visual processing (graphs and/or tables) of information. Five items were classified in both analytic and visual categories, since the items allowed for both analytic and visual processing of information. ConQuest software will be used to identify students' ability on function concepts for both analytic and visual function items by building several item response theory (IRT) models. Analysis of specific function-related items will focus on identifying particular areas of challenge for students, whether in the presentation (visual versus analytic) or in the function concept that the item draws upon.

Results

While final analysis of NAEP function items is still underway, the following released NAEP items illustrate how representations may impact students' ability to recognize and manipulate functions. The correct response is marked as (*). Item 1 offers an example of a question that elicits an analytical approach to the concept of functions.

Table 1: Items 1 (Analytic)

Yvonne has studied the cost of tickets over time for her favorite sports team. She has created a model to predict the cost of a ticket in the future. Let *C* represent the cost of a ticket in dollars and *y* represent the number of years in the future. Her model is as follows: $C = 2.50\,y + 13$. Based on this model, how much will the cost of a ticket <u>increase</u> in two years? (**A**) \$5 (**B**) \$8 (**C**) \$13 (**D**) \$18 (**E**) \$26
Student Responses: A 26%* B 7% C 10% D 50% E 5% Omitted 2%

The high percentage of students choosing the incorrect choice D has one obvious explanation in a failure to carefully read the question. The analytic presentation invites computational manipulation (plugging in a number) without significant reflection on the concepts involved.

Table 2: Item 2 (Visual and Analytic)

A random sample of graduates from a particular college program reported their ages and incomes in response to a survey. Each point on the scatterplot represents the age and income of a different graduate. Of the following equations, which best fits the data? (**A**) $y = -1,000x + 15,000$ (**B**) $y = 1,000x$ (**C**) $y = 1,000x + 15,000$ (**D**) $y = 10,000x$ (**E**) $y = 10,000x + 15,000$	Student Responses: A 4% B 11% C 45%* D 16% E 22% Omitted 2%	

27% of students responded with B or D; both answer choices reflect a failure to visualize the y-intercept of the line of best fit. Because this item draws on both algebra (linear functions) and statistics (scatterplot), it demonstrates the challenge of engaging with functions when the context is not limited to one domain. This item also reflects the conceptual difficulty of crossing from visual to analytical representations of functions.

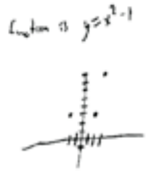
Table 3: Item 3 (Visual) with Sample Responses

The table shows all the ordered pairs (x, y) that define a relation between the variables x and y. Is y a function of x? Give a reason for your answer.	x | y −2 | 3 −1 | 0 0 | −1 1 | 0 2 | 3 3 | 8	**Student Responses:** 53% of students answered the first part of the question correctly. Only 14% of the students gave a valid reason (for each x-value (domain) there is only one associated y-value (range).

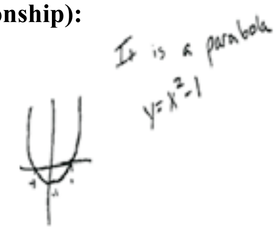
Sample Responses (demonstrating weak or no support for a functional relationship):

Because none of the numbers even relate
A there is no pattern.

C.



B.



In Sample Response A, the student does not recognize the non-linear pattern of the quadratic function as represented in the table, suggesting that he/she has a limited visual concept of functions (one that may only address linear functions). In Sample Response B, the equation $y = x^2 - 1$ does satisfy the ordered pairs on the table, but it is not the only possible function that would do so. Similarly, Sample Response C provides an illustration of one function but fails to recognize that numerous alternative illustrations connecting the ordered pairs exist.

This item asks students to give the definition of a function, but by providing a table of ordered pairs, it invites some consideration of graphical representation. On the one hand, this may have led some students to plot points and recognize a function, resulting in a partially correct response. On the other hand, however, the provision of the table may have also led some students to confuse illustration with justification, a confusion related to incomplete understanding of the essential properties of a functional relationship.

Conclusion

These examples illustrate that there is much to gain from considering the ways in which students engage with function concepts, both in terms of visual or analytic presentation and in terms of the cross-curricular relevance of this concept. As the study progresses, we hope to identify a pattern of performance based on these factors. Already, systematic attention to visual and analytic representations and to the contextual elements of the items (whether they trigger students' existing understanding of functions) has provided a fuller picture of what the nation's students know about functions and where we might best direct our efforts in developing curriculum and instruction.

USING VIDEOS TO THINK MORE DEEPLY ABOUT HOW CHILDREN LEARN MATHEMATICS

David M. Pratt
Purdue University North Central
dpratt@pnc.edu

David Feikes
Purdue University North Central
dfeikes@pnc.edu

Videos of children learning math (along with associated commentary) designed for preservice teachers and teachers can be a useful resource to broaden preservice and teachers' knowledge of how children learn mathematics. This study reports the results of an online survey given to 69 undergraduates and 10 graduate students after watching a video of elementary children engaged in the same mathematical activity. Emergent themes from the analysis of the undergraduates responses were: children solve problems in a multiple ways, adults think about mathematics differently than children, and teaching is not telling. Teacher results contrasted with undergraduates in that they demonstrated a greater recognition for the need for manipulatives and richer, classroom based responses. The videos impacted participants' knowledge of how children learn mathematics and their views on teaching children mathematics.

Keywords: Mathematical Knowledge for Teaching, Teacher Education-Inservice/Professional Development, Teacher Education-Preservice, Problem Solving

Recent innovations in mathematics education have included the use of videos with both preservice and in-service teachers. This paper will examine how videos showing children's mathematical thinking have been used with teachers and prospective teachers. Our research project was developed to illustrate children's understanding of mathematics. These videos consist of one-on-one interviews with children. The videos have been edited to show how children learn and think about mathematics. In many cases we combined clips of different children working the same problem to illustrate not only how children think, but also to demonstrate how different children think differently about the same problem. We have added introductory commentary to focus the viewing experience (Sherin & van Es, 2005) on pertinent concepts regarding how children learn mathematics. We have also added commentary at the conclusion of each video clip which is intended to provoke viewers to ask more questions about how children learn mathematics and how to foster children's mathematical learning.

Theoretical Framework

The results reported in this paper are part of a larger study to determine the influence of videos on understanding how children learn mathematics. One of the central questions is how does the viewing of video of children engaging in mathematics activities affect preservice teachers' Mathematics Content Knowledge (MCK). In a prior study, we found that preservice teachers who used written materials about how children learn mathematics compared with a control group who did not use these materials had no significant difference in mathematical scores. However, there were significant differences in efficacy, beliefs, and knowledge of how children learn mathematics (Feikes, Pratt, Hough, 2006). One study (Philipp, et. a., 2007) has shown that videos can impact preservice teachers MCK. However, examining this knowledge with a finer lens it appears that Mathematical Knowledge for Teaching (MKT) is very context bound. This and other studies (Philipp, et al, 2007; Feikes, et. al, 2010) have shown that videos

can impact the Pedagogical Content Knowledge of (PCK) of preservice teachers and subsequent teaching of mathematics to children. Learning from our prior experiences we hypothesize that we must look closely at knowledge of how children learn mathematics.

Videos can be a powerful tool in helping preservice teachers expand their content knowledge (Philips, et al 2007) their Mathematical Knowledge for Teaching (Bell, Wilson, Higgins, & McCoach, 2010) and in developing beliefs that promote developing mathematical understanding (Superfine & Li, 2011). One of the key features of using videos is in helping viewers of the videos *notice* (Jacobs, Lamb & Philipp, 2010) what is important in children's learning of mathematics. What viewers attend to and not attend to is significant in the use of these tools. The videos and especially the narration included at the beginning and end of these videos were designed to help viewers make sense of the video and focus on or notice children' mathematical thinking. Videos have been shown to help teachers modify their focus from pedagogy to students' mathematical thinking (Sherin & van Es, 2005).

Methodology

This smaller study examines and compares the responses of an online survey of two groups of students that was required of both groups as a homework assignment. The first was a group (three sections) of preservice teachers in the second course of a series of three mathematical content courses for elementary teachers. The second was a class of ten practicing teachers taking a graduate mathematics education course on teaching mathematics in the elementary school.

The assignment was to go to a website and watch a video of three second grade students solving the following problem: Mary has 18 marbles. She has blue, green, and yellow marbles. She has 7 blue marbles and 6 green marbles. How many yellow marbles does she have?

After watching the video, the students were required to complete an online survey which required them to submit a written response to five questions. A constant comparative analysis (Strauss & Corbin, 1998) was used to code the open ended survey questions to develop emergent themes. Students were required to put their names on the survey. After some brief commentary, three different students solve the same problem.

In the video the first child selects two numbers from the problem, puts them in column form and either adds or subtracts. She initially wrote 7 - 6 = 1, realized that was not correct and then wrote18 -7 = 11. From the video it is apparent that she knows these solutions were not correct. Without any provocation she begins using the cubes which were next to her the entire time to solve the problem. The second student decides to draw a picture. She colors 8 blue, 7 green and counts the rest to realize she has 6 yellow. The last child does the problem in his head he adds 7 + 6 = 13 and subtracts 13 from 18 to get 5.

Results and Discussion

The following is our initial attempts to analyze the results. We are looking for what did the preservice teachers and teachers learn or perhaps more appropriately glean from watching these videos and reflecting upon. Second we were looking for differences between the two groups.

The first question asked: How did the video help you think more deeply about how children learn mathematics or teaching mathematics to children?

For the undergraduates a common theme that emerged was: children solve problems in multiple ways or have different thought processes in solving the same problem. For example: "I saw that students all use different method… hands on, drawing a picture, and counting up are the three methods that were used in the video."

These results were expected given the nature of the video and the accompanying narration that attempted to direct thinking and noticing. However, an aspect more open to interpretation was the question: "How did the video help you think more deeply about teaching mathematics to children?" The video did not explicitly tell them how to teach and only the last narration suggested how to teach children mathematics. Following are some excerpts that illustrate what preservice teachers took form the video about teaching:

> *Preservice Teacher:* This video really helped me grasp just how important it is to teach multiple ways of thinking and ways of solving problems. Pictures, manipulatives, and mental math are all tactics that children should utilize [sic] and learn at a young age to allow their minds to be able to go back and fourth [sic], depending on the problem, to help them solve the problem.

These responses illustrate that the videos were useful tools in helping students realize that children think about mathematics in different ways. This data also indicates the students were thinking about how they would teach children mathematics. A key finding is the knowledge of how children learn mathematics is the primary emphasis for how they think about teaching.

A second theme that emerged was that preservice teachers appeared to come to the realization that children's thinking is different from how adults or they themselves think about mathematics.

> *Preservice Teacher:* The video made me think more deeply about how children learn mathematics because as an adult we would solve this problem similar to the last young man in the video, but to me an efficient teacher we must understand that all children learn differently. Some children need pictures and manipulatives like this video shows, because they learn at different paces and may not be able to do it how you would do it.

Another theme that emerged was; Teaching is not Telling. Some preservice teachers came to understand that learning takes time and that teachers must be patient and not just tell children the answers and how to solve problems. Other themes that emerged were the importance of manipulatives, the use of pictures, different children solve the same problem differently, and learning mathematics can be exciting.

Similar themes emerged from the graduate students who were all K-6 teachers. However, their responses were richer and often related to their actual practices.

> *Graduate:* There are several ways a child might solve a multi-step problem; manipulatives, drawing pictures, or mental math. There is no correct way to solve it, but the visual aspect is more important some children than to others.

Significant in this response is the knowledge is there is "no correct way" to solve the problem. Often the undergraduates implied that they would have to teach children these different ways. Their intent is the same but their methods of achieving the result are different. Both recognize that children solve problems in different ways but several of the preservice teachers believed they had to directly teach these ways to children.

Teachers were able to elaborate more on what they did not see or what did not work. These teachers seemed focused in developing children's thinking and not just seeing that children solve problems in different ways or even in how to teach problem solving to children.

A final contrasting theme that emerged was that 13 out of 69 or 19% of undergraduate respondents mentioned manipulatives in their response. However, 4 out of 10 or 40% of teachers mentioned manipulatives. While the number of teachers is too small to make valid inferences it does suggest a difference between the two groups. Undergraduates are continually told about the importance of manipulatives and the majority of these students had a mathematical course the semester before where manipulatives were used and emphasized. Teachers, likely have had similar experiences in their undergraduate education and teacher workshops. However, given the realities of the classroom, teachers may not be using manipulatives as much as they feel they should. One teacher said, "I need to make them more available than they are."

Conclusions

Our study and the data collection techniques continue to evolve. We continue to refine the process of making videos, from the location of the camera angle, how to get better sound quality, what narration to include, and how to disseminate the videos on a larger scale.

These courses were all taught by the first author. As this is a design experiment we intend to use the results and the insights we gained in methodology to conduct a larger study at external sites with treatment and control groups. A significant contribution of this study is the responses of the practicing teachers.

University of Illinois at Chicago
wli26@uic.edu

Our study investigates the use of a particular practice, connecting to teaching practice, employed by mathematics teacher educators in teaching mathematics content courses for elementary preservice teachers. Six mathematics teacher educators, all with experience in teaching content courses for elementary preservice teachers, participated in this study. In an interview setting, the participants described whether, how and why, in their teaching of mathematics content courses, they connect teaching practice to the mathematics content they teach. We first discuss what they do to connect teaching practice to content learning. Then, we discuss participants' rationales for engaging in this particular practice. Overall, we found that practicing components of K-12 teaching, using artifacts of teaching and learning, and modeling are three common strategies that these mathematics teacher educators use to connect preservice teachers' learning to teaching practice in mathematics content courses.

Keywords: Mathematics Teacher Educators, Teacher Education-Preservice, Mathematical Knowledge for Teaching, Instructional Activities and Practices

Introduction

The field of teacher education lacks an evidentiary base for understanding the practices of mathematics teacher educators (MTEs), professionals who work with practicing and/or PSTs to develop and improve mathematics teaching (Jaworski & Wood, 2008). Though there has been some exploratory work in this domain (see Jaworksi & Wood, 2008), currently there has been no synthesis of what MTEs need to know and do in order to support PSTs in developing mathematical knowledge in ways needed for teaching. In this study, we shift the focus of research on mathematics teacher education from what did PSTs learn to what is the work of MTEs as they supported PSTs' learning where "work of MTEs" refers to the practices in which MTEs engage inside the university classroom. Our study takes place in the context of a two-year professional development program for MTEs, and examines the work of six MTEs as they support PSTs' learning of mathematics. Our study is guided by the following question: In what ways do MTEs connect to teaching practice in mathematics content courses for elementary PSTs?

Background

In his work focused on teacher educators, Mason (1998) suggests that the work of MTEs is similar to that of teachers and that, in addition, the work of MTEs involves helping PSTs recognize how to relate what they are learning to teaching. Specifically, he suggests that the work of MTEs involves developing and enhancing different levels of awareness in PSTs, as opposed to simply helping them learn the content that needs to be learned. Attention may be drawn to actions which are being carried out with lesser or greater awareness, so that in the future the learner might become aware of a possibility of choosing actions according to the circumstances (Mason, 1998). PSTs need to be able to engineer instructional situations in which

students experience a shift in their attention where they (i.e., students) become aware of ideas and concepts of which they were previously unaware. Consequently, the work for MTEs is to develop PSTs' understanding of certain mathematical ideas and concepts, and develop PSTs' awareness of how to connect what they are learning to teaching. For example, MTEs must not only develop PSTs' ability to evaluate the transparency of mathematical ideas in representations for themselves as learners, but also support PSTs in recognizing why evaluating the transparency of representations is important for planning lessons and selecting representations that will support the development of student's understandings. Thus, the work of MTEs involves helping PSTs become aware of how what they are learning about mathematics is connected to teaching practice.

Method

To understand MTEs' practice of connecting teaching practice, we employed a grounded theory research design (Strauss & Corbin, 2007) to allow the practices to emerge from MTEs' descriptions of their own teaching practices. Six MTEs, four female and two male, all with experience in teaching content courses for elementary PSTs, participated in this study. All names are pseudonyms. Individual semi-structured interviews were conducted by the authors to probe MTEs' understanding of mathematical knowledge needed for teaching, their perceptions of the nature of their work as MTEs, and the rationales for their course design.

All interviews were transcribed and independently coded by the authors. All discrepancies were resolved through discussion. We conducted three rounds of open coding as part of the analysis process, which involved highlighting transcript segments about MTEs' perceptions of and practices used in teaching, categorizing segments into three broad categories (i.e., MTE practice, conception of knowledge and skills PSTs need, conception of a content course), and then developing related sub-categories, including connecting to teaching practice and assessing PSTs' learning, among others, to provide more detail about the three broader categories. For our current study, we focus only on the results of the coding analysis around the connecting to teaching practice category and related sub-categories.

Results

In this section, we first discuss the ways they connect to teaching practice, and then discuss their rationales for connecting to teaching practice in their content courses. Overall, we found that all six MTEs connect PSTs' learning of mathematics to teaching practice in their content course, albeit to varying degrees. We identified three primary strategies by which MTEs reported connecting to teaching practice: (1) having PSTs practice components of teaching, (2) using artifacts of teaching and learning, and (3) modeling teaching.

What Are the Ways in Which MTEs Connect to Teaching Practice?

Having PSTs practice components of teaching was the most common strategy that MTEs reported using to connect math content learning and teaching practice in their courses. This strategy involved having PSTs "try out" what a teacher might have to manage in the classroom. For example, using questions situated in K-12 teaching practice as a journal prompt for PSTs (e.g., As a teacher, I will use tasks to promote…); acting like a student to create teacher-student interaction situations; eliciting PSTs' experience working with students; having PSTs consider the context of teaching at a specific grade level; considering students' common misconceptions; having PSTs analyze math curriculum standards; and having PSTs explain mathematical

thinking.

Using artifacts of teaching and learning was another common strategy used by the MTE participants. MTEs reported using the following artifacts of teaching and learning to connect content learning and teaching practice: showing videos of students doing math, providing anecdotal stories about currently practicing teachers as well as anecdotes about students' thinking and misconceptions, encouraging PSTs to share stories about students' learning, discussing education policy reforms, analyzing a task from an elementary textbook, and providing opportunities for PSTs to familiarize themselves with manipulatives.

Modeling was another strategy that MTEs reported using to connect PSTs' learning to teaching practice. Two particular ways of modeling were reported: MTEs modeling "good teaching" and not just lecturing, and MTEs modeling how to interact with students.

Rationales for Connecting to Teaching Practice in Their Content Course

In the interviews, MTEs were asked to explain why they connected preservice teacher learning to teaching practice, and how this practice was important for PSTs' development as teachers of mathematics. Due to space constraints, we only discuss rationales from three MTEs.

Nancy: Get them to think deeply about the content they are going to teach. Nancy felt strongly that a math content course should always include an emphasis on teaching practice. She claimed that learning mathematics in the context of teaching practice encourages PSTs to approach math conceptually and to move beyond rote memorization.

> They're (PSTs) in the process of learning it (the mathematics) themselves, so if you put it in the context of how you would teach this to someone else, it forces them to think differently from "oh, I have to memorize this."

Nancy mentioned that her goal is to emphasize process and understanding. The challenge of achieving this goal is to get PSTs to agree on the importance of learning mathematics conceptually. The fact that PSTs will be teachers provides an opportunity for her to engage PSTs in deeper learning. In order to get PSTs to think deeply about the math content, Nancy made explicit the ideas that what they learn is what their future students are going to learn. She also reported using questions, like "what if a kid asks me this?", as a journal prompt to support PSTs in assessing their own understanding. In addition, she reported often acting like a student in order to create situations to motivate PSTs to understand the knowledge required for engaging students with the content.

Edward: I have to teach mathematics to them in a way they will hopefully replicate when they get back out there. Edward's goal for PSTs in his content course is to experience mathematics in an enjoyable and deep way. He believes that it is difficult to engage PSTs' learning of mathematics for understanding, if they do not enjoy learning mathematics. Moreover, he claimed the way we teach PSTs mathematics and the way we want PSTs to teach in the future should be consistent; and for most PSTs, the way that they learned mathematics was not the way we want them to teach their students. So, in his content course, he aimed to teach PSTs mathematics in a way that they will teach in the future.

> It is hard to say that it's okay both teaching the content this way but we want them to do it that way. I've gotta teach it to them in a way that'll hopefully replicate when they get back out there. Many of them haven't done it in that way, so I think just doing it in a way that we hope they would do it.

To achieve this goal, Edward claimed that he had to model a lot how he would teach students. In addition to modeling, Edward reported highlighting aspects of teaching as PSTs practiced components of teaching in class. He provided an example involving explanation. He would find PSTs who provided clear explanations and drew clear pictures during their presentation, and then he would point out the positive features and say: "Wouldn't you want this person to be your teacher?" He believes that highlighting aspects of teaching from PSTs helps them to see teaching standards from their peers. He also reported sharing anecdotes of K-12 teachers' misunderstanding of mathematics content to PSTs in his course.

David: The beauty of mathematics is not gonna teach someone how to be a great teacher. David's approach to teaching content courses is characterized by integrating mathematics and pedagogy. He stated that PSTs need to, at the minimum, know the mathematics that they are going to teach. Learning mathematics content and teaching mathematics should not be separated. He leans towards pedagogy or teaching through the methods. He explained, teaching through methods has the potential to motivate PSTs' learning; also, it provides opportunities to engage with both mathematics content and pedagogy.

> If I'm teaching through the methods, it's a good selling point. Watching children engage in mathematics and seeing how a teacher responds to children is both methods and content. … You have to extract the content out of that to make it meaningful.

Moreover, David pointed out that some of the mathematics knowledge is particularly required for teaching. Without connecting to classroom teaching practice, teaching this kind of knowledge could be mechanical.

> I can teach them why long division works, why different subtraction models. Unless we tie that to actual classroom practice, there might be some type of disconnecting there (the mathematics content PSTs learn and the mathematics they need to teach).

Similar to previous participants, he values the practices of modeling good teaching in a content course. He believes that PSTs take away not only the content but also the way MTEs teach the content.

Conclusion

The purpose of our study is to understand the ways in which MTEs connect PSTs' learning of math to teaching practice in content courses. Through semi-structured interviews, we found that connecting teaching practice to PSTs' content learning was a common practice for these MTEs, but carried out in different ways. Results of our analysis contribute to our limited understanding of the work of MTEs in three ways: 1) provides empirical evidence of the existence of the connecting to teaching practice as part of MTEs' work; 2) provides evidence of the different strategies by which MTEs connect to teaching practice; and 3) elucidates MTEs' rationales for engaging in this particular practice as part of their work.

INSTRUCTIONAL FACTORS AFFECTING SECOND-GRADERS' CONCEPTUAL AND PROCEDURAL KNOWLEDGE OF PLACE VALUE CONCEPTS

Emmanuelle Adrien

Helena P. Osana
Concordia University
osana@education.concordia.ca

The benefits of mathematics teaching that focuses on conceptual understanding have been well documented, and previous research has also demonstrated the merits of learning procedures (Rittle-Johnson et al., 2001). Students also need to understand how the two are connected (Hiebert, 1992), but there is no consensus on the most efficient ways to teach for such connected understanding in mathematics. There is some evidence that the order in which lessons are presented has an impact on mathematics learning, and that alternating between concepts and procedures is more effective than introducing concepts before procedures (Rittle-Johnson & Koedinger, 2009). In addition, several have suggested that teachers must make explicit connections between concepts and procedures (e.g., Uttal, 2003), but little systematic research exists to support this claim in early mathematics learning. In the present study, we investigated (a) how the order of presentation of concepts and procedures would impact children's conceptual understanding of place value and procedural execution of addition strategies, and (b) whether the level of explicitness in linking concepts and procedures would moderate these effects.

Eighty-seven ($N = 87$) second-grade students from a suburban school district in Canada were randomly assigned to one of six conditions; each was a different combination of lesson **order** (concepts-first, procedures-first, iterative) and level of **explicitness** during instruction (explicit, not explicit). Students were asked to solve a series of conceptual (e.g., In $\underline{7}1$, how much is the underlined number worth?) and procedural (e.g., 32 + 19) problems before and after instruction.

Two 2 (time) x 2 (explicitness) x 3 (order) repeated measures ANOVAs were performed, with time as the repeated measures factor and explicitness and order as the between group factors. The outcome measures were performance on conceptual tasks and procedural tasks, respectively. For both conceptual and procedural measures, there was a main effect of time (ps < .001), indicating improved performance from pretest to posttest. The analyses also yielded an interaction between explicitness and order for conceptual tasks, $F(2, 81) = 3.230$, $p < .05$, and for procedural tasks, $F(2, 81) = 7.374$, $p < .01$, revealing in both cases that making explicit connections was particularly beneficial for students in the procedures-first group.

These findings suggest that teachers should make explicit connections between concepts and procedures when teaching addition and place value, particularly if students are first introduced to mathematical procedures.

DO CONCRETE SYMBOLS FACILITATE FRACTION LEARNING?

Kate Herold
University of Minnesota
khherold@umn.edu

Michele Mazzocco
University of Minnesota
mazzocco@umn.edu

Keywords: Rational Numbers, Elementary School Education, Number Concepts and Operations

A common approach to math instruction is the use of concrete representations to teach abstract concepts. Concrete representations have been described as "contextual, real world examples" (Kaminski et al., in press) and can include physical manipulatives, visual representations, or computer animations (Kaminski et al. in press; McNeil & Uttal, 2009). One area of math instruction in which the use of concrete symbols is particularly pervasive is the teaching of fractions, especially for children with a mathematics learning disability (MLD). However, it is not clear whether the use of concrete materials improves fractions instruction and, if it does, whether it does so equally for all children. For instance, children with MLD or low achievement in mathematics (LA) continue to underperform on fraction items relative to their typically achieving (TA) peers (AUTHOR, 2008). In this longitudinal study we examine whether the use of concrete representations to teach fractions affects performance, and if the effects are comparable across these three groups of children.

Participants were 159 students (seen at Grades 4 and 5), who were classified as having MLD (n=16), LA (n=26) or TA (n=117). We used the *Symbolic Magnitude Comparison of Fractions* (SymMCoF) task to measure children's knowledge of fractions. The SymMCoF includes pairs of fractions represented as visual models, presented with either standard or expanded and contextualized concrete instructions. In each of these two conditions, children identified the larger item in the fraction pairs or could indicate that the pair was equivalent.

Overall, participants were *less* accurate in the concrete versus the standard condition. Using repeated measures ANOVA we found a main effect of condition, $F(1, 156) = 22.081$, $p < .00001$, $\eta^2_p = .124$, with slightly more accurate performance in the standard (70%) versus concrete condition (65%), Cohen's $d = .24$, and a main effect of MLD status $F(2, 156) = 27.023$, $p < .00001$, $\eta^2_p = .257$. Post-hoc comparisons revealed that, in Grade 4, children with MLD performed no differently from their LA peers on both standard ($p = .06$) and concrete visual models ($p = .10$), whereas, in Grade five, children with MLD were less accurate than children with LA on both standard (MLD = 61%, LA = 75%) and concrete visual models (MLD = 55%, LA = 72%; $ps < .003$).

Results from this study indicate that using additional concrete instructions does not improve understanding of fractions during the SymMCoF. In fact, participants were more accurate on items presented under the standard condition. In follow-up analyses, we explored whether working memory or executive function contributed to accuracy levels in the concrete condition.

CONTRIBUTIONS OF VISUAL REPRESENTATIONS TO STUDENTS' RATIONAL NUMBER REASONING AS THEY SOLVE EQUAL SHARING PROBLEMS

Gayle M. Millsaps

millsaps@purduecal.edu

Diana L. Underwood-Gregg
Purdue University Calumet
diana@purduecal.edu

Keywords: Elementary School Education, Rational Numbers, Instructional activities and practices, Learning Progressions

Empson and Levi (2011) observe that the types of visual representations for rational number reasoning that students encounter in K-6 education "offer few opportunities for children to make connections between fractions and whole numbers" (p. 7). Although Cobb, Yackel, and Wood (1992) warned there is an inherent problem with expecting students to use representations to construct mathematical relationships, Empson and Levi (2011) observe, "learning to create fractional quantities on their own using part-whole and other kinds of representations contributes to children's understanding of fractions" [rational numbers], "because to create workable representations, they need to reason about relationships, such as how the number of parts is related to the whole unit or how the ratio of sharers to shared is related to each person's share" (p. 28). As a classroom community develops ways of symbolizing through the use of visual representations that they create and use, visual representations become "taken-as-shared" symbols by the classroom community for communicating the mathematical relationships that they are constructing—the mathematical relationships that contribute to students' construction of the meaning for rational numbers. This study documents how visual representations provide both support for and information about students' development of rational number reasoning.

Researchers observed third grade students as they solved equal sharing problems in an inquiry classroom setting. Small groups or pairs of students were given equal sharing problems to solve by their teacher. Researchers observed the students' use of visual representations whether self-created or provided by the teacher. Students' use of visual representations was examined for information about how the children were thinking as they solved the problems, how the visual representations supported or did not support their reasoning during the problem solving process, and how students' use of visual representations provided information about what the students understood about rational numbers.

Analysis of the data revealed that the students were most successful when provided visual representations that allowed for ease of partitioning. Students who showed the most progress by the end of the study were able to partition the visual representations of wholes, distribute equal parts, and then recombine the distributed parts into wholes when appropriate. They answered with appropriate mixed numbers and were able to explain their work. Students who made moderate progress either partitioned the visual representations of wholes, distributed the parts equally, answering with an improper faction, or distributed the wholes and only partitioned wholes that could not be distributed, answering with a mixed number. They were not able to relate the two types of answers.

METAPHORS STUDENTS EXPRESS ABOUT INTEGERS AFTER USING MULTIPLE MODELS

Julie Nurnberger-Haag
Michigan State University
nurnber3@msu.edu

Keywords: Number Concepts and Operations, Cognition, Learning Theories, Metaphor

Student thinking and skills regarding negative numbers have been extensively studied in order to help students overcome the difficult transition from whole number to negative quantity fluency (e.g., Kilhamn, 2011; Vlassis, 2004), but investigation of the underlying conceptual mechanisms on which we might capitalize have only just begun. Educators and researchers have used many different pedagogical models in their attempts to help students extend their concept of number to negatives. Different models, however, likely activate different conceptual metaphors. Prior research on the conceptual metaphors underlying negative numbers has focused on the metaphors of the mathematics (*object collection*—numbers as things, *measuring stick*—numbers as static lengths, and *motion along a path*—numbers as locations and operations as movements), comparing student with adult use of metaphors, or longitudinal student learning with a teacher who tried to avoid specific models (e.g., use of number line, or chip models) (Chiu, 2001; Kilhamn, 2011; Lakoff & Nunez, 2000). These prior reports of student thinking focused on verbal explanations, including drawings only if students spontaneously created them.

The preliminary data reported here were collected during the piloting of a measure for a larger study from four heterogeneous sections of seventh-grade students (n=95) whose teacher used the *Connected Mathematics Program* (*CMP*). CMP uses a chip model, a number line model, and encourages generalization of rules. The chip model uses the underlying idea of an object collection metaphor, whereas the number line model as promoted in CMP combines a measuring stick and motion along a path metaphor. The research question was: What types of metaphorical and rule-based reasoning did students who experienced multiple models of integers demonstrate? I report results from three items of a written assessment in which I prompted the students who had studied negative numbers to include a drawing in their explanations to students who had not yet studied negative numbers. These items asked questions like *Which number is smaller? What does* ${}^{-}3 - {}^{-}5$ *mean?* and *What does* ${}^{-}152 - {}^{-}85$ *mean?* Written explanations and drawings were coded for use of rules and conceptual metaphors. Preliminary data showed 54% of students used procedures or rules and 88% used conceptual metaphors to explain integers and integer subtraction. Students infrequently used an *object collection* metaphor (25%) or portrayed a number line with a *measuring stick* metaphor (19%). Most students (73%) used a number line representation in ways consistent with the *motion along a path* metaphor, conceiving of numbers as points located on a path. Future research should assess what students learn via each metaphor.

CHILDREN'S AND ADULTS' USE OF MODELS OF WHOLE NUMBER DIVISION: CONSISTENCY OR VARIABILITY?

Pooja G. Sidney
University of Wisconsin – Madison
pgupta6@wisc.edu

Martha W. Alibali
University of Wisconsin – Madison
mwalibali@wisc.edu

Keywords: Number concepts and operations, learning trajectories, elementary school education

Does children's knowledge about whole number division influence their learning of fraction division? Division by fractions is a notoriously difficult topic in arithmetic, and both children (e.g., Siegler, Thompson, & Schneider, 2011) and adults (e.g., Ma, 1999) struggle to represent its conceptual structure. One potential barrier to a deep understanding of fraction division may be children's intuitive models of whole number division. Children rely primarily on partitive models for whole number division (Fischbein, Deri, Nello & Marino, 1985). However, fraction division is better understood within a quotative model of division. Thus, children's early partitive models of division may pose barriers for understanding fraction division.

The primary aim of this study was to describe the frequency and consistency with which children and adults use partitive or quotative models of division, across a variety of tasks. To address this question, third-graders, fourth-graders, and adults were asked to solve division problems in three contexts: an *object* task (using counting chips to represent a division problem), a *story* task (generate a story to match a division problem), and a *number line* task (demonstrate a division problem using the number line). Each participant solved one division problem in each context, and their models of division (*partitive, quotative, other*, or *no model*) were coded.

Both groups of children as well as adults spontaneously drew on both partitive and quotative models to model whole number division (Grade 3: 45% partitive, 40% quotative, Grade 4: 62% partitive, 24% quotative; Adults, 44% partitive, 33% quotative). Furthermore, most participants in each age group relied on multiple models within a single session. Variability in model use across tasks was examined among participants who were variable in their model use. In the *object context*, most 3rd- and 4th-graders relied on a partitive model, whereas adults were more varied. In the *story context*, 3rd-graders were about equally likely to employ each of the two division models, whereas most 4th-graders and adults used a partitive model. In the *number line* context, the majority of trials in all age groups were classified as quotative.

In contrast to prior work, we found that many children spontaneously used quotative models of division. This is due, in part to the number line context, which was not included in prior studies. However, many current reform curricula introduce and provide children practice with measurement models, and this may support quotative reasoning on the number line task. Given children's spontaneous use of the quotative model in the number line context, and the finding that fraction division is easier to conceptualize within a quotative model (Fischbein et al., 1985), the number line may be particularly useful in fraction division instruction.

THE ROLE OF UNITS COORDINATION IN CONSTRUCTING AN ADDITIVE RELATIONSHIP BETWEEN SIGNED NUMBERS

Catherine Ulrich
Virginia Tech
culrich@vt.edu

Beginning in Spring 2011, I conducted a semester-long constructivist teaching experiment (Steffe & Ulrich, 2013) with four sixth-grade students in order to investigate how the mathematics of each student, including schemes for unsigned quantities, affected the nature of the additive relationships that the students were able to construct between signed numbers. During the study the two students with the most sophisticated unsigned number schemes independently constructed a strategy that I call *reasoning through zero,* which corresponds to a behavior Peled, Mukhopadhyay, and Resnick (1989) identified as representing (at least) the use of a mental Divided Number Line. More surprising was that the other two students, one of whom had relatively sophisticated ways of operating with whole numbers and fractions, experienced great difficulty in trying to utilize this same type of strategy. Based on empirical and conceptual analysis, I hypothesize that the multiplicative coordination of three levels of units must be interiorized before students can independently develop this strategy. Research (e.g., Steffe & Olive, 2010) indicates that coordinating three levels of units is important across both fractional and algebraic contexts as well, although the coordinations in both of those contexts are multiplicative instead of additive.

Consider the following example of *reasoning through 0* when a student is finding the total displacement from 0 after a trip of -29 and a trip of +37: “I got +8 because I added +29 to that [sketch of -29 trip] and it made it 0 again. Then from 29 to 37 it is 8m...[The 8m] is coming from the 37.” Reasoning through zero involves the ability to partition the second addend (+37) into the additive inverse (+29) of the first addend and its complement (+8), the overall change in value. The reason that the process would be any harder than, say, subtracting 29 from 37, which does not require the coordination of three levels of units, is that the student must maintain an additive comparison with the original reference point as he or she counts past zero in order to recognize the sign of the total change. Therefore, *the partition of the second addend that extends past 0 must maintain its status as a subsequence of the second addend* in order to inherent the sign of the second addend. I believe that the student must form this three-levels-of-units structure as he or she begins to apply the second addend in order to keep track of their position with respect to the beginning of the second addend’s number sequence (the right-hand dotted line) as well as their position with respect to the original reference point. This means that they are not only forming three levels of units in action, but are monitoring and adjusting the three-levels-of-units structure as they continue counting past zero. This monitoring would be quite difficult for a student who has not yet interiorized the three-levels-of-units additive structure.

MAKING SENSE OF COMPLEX NUMBERS THROUGH THE USE OF STUDENTS' PREVIOUS KNOWLEDGE

Gabriella Elizabeth Vargas
University of Illinois at Urbana Champaign
gvargas2@illinois.edu

Keywords: Algebra and Algebraic Thinking; Instructional Activities and Practices; Standards; Problem Solving

In conversation with the nature of mathematics is the need to have students make sense of complex numbers. The common core state standards for mathematics (CCSSM) recommend introducing the complex number system towards the end of students' mathematical careers, starting in Algebra Two (CCSSM, 2010). In learning the complex number system, students are also expected to learn how to algebraically manipulate them and solve for complex zeros. Moreover, CCSSM emphasize the importance of students making connections to existing knowledge, but are not clear in *how* to achieve this goal when working with Complex Numbers. Research has shown that incorporating proofs and mathematical task can help facilitate understanding of mathematical concepts (Henningsen & Stein,1997). However, opportunities to use proof are often limited in textbooks (Thompson et al., 2012); when they are presented, students have difficulty producing proofs that teachers would consider satisfactory (Healy & Hoyles, 2000).

The goal of this poster is to present a method to connect students' knowledge of Real and Natural Numbers to Complex Numbers. The lesson asks students in a group discussion to recall the definitions of distributive, associative, and commutative rules. After students report back to the larger group, the teacher introduces the rule of how complex numbers and the idea of *a+bi* is a complex number and how the definition of an imaginary number as i^2=1. Students then are instructed to work through a proof through geometrical representations with their group to reason why the distributive laws hold for complex numbers.

By providing students with more opportunities to work with proofs, students are exposed to multiple representations of the complex numbers allowing them to see different lenses as to how to work with the rules. Specifically, students work with *mindful manipulations* in order to understand the proofs of the distributive properties as well as *implement strategies* to see the connections of how and why the distributive laws hold for complex numbers (Graham et al., 2010). Ultimately, proofs can help scaffold onto students' previous knowledge so that the new knowledge they develop is consistent and meaningful.

CONTEXTS OF STUDENT-CONSTRUCTED STORIES ABOUT NEGATIVE INTEGERS

Nicole M. Wessman-Enzinger
Illinois State University
nmwessm@ilstu.edu

Keywords: Middle School Education, Number Concepts and Operations, Rational Numbers

A holistic understanding of number is abstract and challenging; however, negative integers are particularly difficult because they cannot be physically modeled in the world. Because of this, connecting negative integers to contexts provides a typical pedagogical tool to explain the existence and relevance of negative integers. The *Common Core State Standards for Mathematics* (Council of Chief State School Officers, 2010) suggested uses of contexts include, "temperature above/below zero, elevation above/below sea level, credits/debits, positive/negative electric charge" (p. 43). However, other studies have shown that negative integers may not intuitively emerge from these contexts for students (e.g., Whitacre, Bishop, Lamb, Phillipp, Schappelle, & Lewis, 2012). This poster will describe a study that aims to investigate the ways students connect negative integers to their world. This study used a story-telling approach (Mukhopadhyay, 1997) as a way to determine how students apply context to negative integers.

Six eighth-grade students from the Midwest, after more than two years of instruction on negative integers in school, participated in this study. Following a semi-structured interview protocol, students constructed stories for ten different open number sentences involving negative integers (i.e., 8 – 20 = ☐, -5 + ☐ = 21). After students constructed their stories, they were asked to reflect on how the number sentences connected to their stories.

Findings show that students did not typically utilize the traditionally advocated contexts (e.g., temperature, elevation) in their stories about negative integers. Of the traditional contexts that the students employed, the students utilized the context of credits/debits most frequently. However, the students did not always use the context of credits/debits in ways that connect to the traditional notions of money. This poster will share specific examples of stories that students constructed that are parallel to the conventional credits/debits contexts and are considered to be non-conventional stories. These non-conventional contexts and what they indicate about students' understanding of integers will also be reported. For example, for the number sentence -17 + 12 = ☐, "I want 17 baseball cards. I got 12 baseball cards. I still want 5 cards" represents a nonconventional context provided by a student. These findings have implications for the types of contexts we use with both instruction and research with integers.

CONCEPTUAL MIS(UNDERSTANDINGS) OF FRACTIONS: FROM AREA MODEL TO MULTIPLE EMBODIMENTS

Xiaofen Zhang
University of Maryland Baltimore County
xzhang2@hotmail.com

Keywords: Rational Numbers, Number Concepts and Operations, Instructional Activities and Practices, Elementary School Education

The idea that area-model approach should take priority in thinking about the teaching and learning of fraction concepts has been emphasized in many elementary textbooks and teaching periodicals (NCTM, 2000). Researchers, however, have questioned the virtue of emphasizing one mode and form of representation of fractions, and advocated the use of multiple embodiment approach (Clements & Lean, 1994). The study was intended to assess knowledge of the unit fractions 1/2, 1/3 and 1/4 of participating end-of-fifth-grade students, and to improve and strengthen their conceptual understandings of the unit fractions.

A paper-and-pencil test was first administered to 40 participants, randomly assigned to two equal-sized groups (Group 1 and Group 2). The Group 1 students were then interviewed and participated in five fractions lessons led by their normal mathematics teacher. Afterwards, all students took a parallel form of the original paper-and-pencil test and were interviewed. The Group 2 students participated in similar fractions lessons, and were re-tested and re-interviewed. About four months later, the students took a parallel form of the paper-and-pencil tests as a retention test. A variety of models including linear, perimeter, discrete, capacity and area models were incorporated into the tests and interview protocol to represent fractions. As to the fractions lessons, there were six distinguishable activities involved during which the students were asked to (a) walk around the boundaries of a large equilateral triangle and a large square that were fixed on the floor, (b) fold paper strips and a piece of rope, (c) pour a full glass of water into identical glasses, (d) share 12 discrete identical blocks, and (e) crouch down and stand up.

Analysis of test results indicated that out of total 28 points, 12 of 40 participating students scored less than or equal to 14 (50%), and 15 scored at least 21 (75%) on the first pre-teaching test; however, only 3 of the students scored less than or equal to 14, and 33 scored at least 21 on post-teaching tests. Before the teaching intervention, many of the students failed to provide correct answers for those tasks where unit fractions were associated with perimeters, capacities, lengths, number lines, and discrete objects, although they were adept at partitioning and shading regional shapes. For example, at the pre-teaching stage, 35% of the students did not locate 1/4 of the way around a square correctly and 45% of them did not locate 1/3 of the way around an equilateral triangle correctly. However, at the post-teaching stage, over 90% of the students were able to respond correctly to these tasks. Students' performances on the retention test were close to their performances on the post-teaching tests, and the students had retained most of the knowledge and concepts that they had learned during the lessons.

This report describes the longitudinal development of one student, Drew, in terms of his unit concepts in area and volume measurement situations across Grades 2 through 5. Data were collected during individual interviews and an open-response assessment within the context of a four-year longitudinal teaching experiment. Results indicate that Drew's use of unit developed over time with respect to identifying and operating on composite units. In addition, his understanding of the conceptual link between the iteration of a composite unit and the application of multiplication in both area and volume measurement contexts developed gradually. Furthermore, changes in his use of unit in an area measurement context often precipitated changes in his use of unit in a volume measurement context.

Keywords: Measurement, Geometry and Geometrical and Spatial Thinking, Learning Trajectories

The development of children's conceptions of spatial measurement has attracted the attention of researchers. However, much of what is known has been studied using cross sectional studies and has focused on only one domain of measurement in isolation (i.e., Battista & Clements, 1996; Battista, Clements, Arnoff, Battista, & Borrow, 1998; Outhred & Mitchelmore, 2000). Therefore, little is known about how children's sense of unit develops over time and connects across domains of spatial measurement. The purpose of this report is to address this gap in the literature by describing the longitudinal growth of one student, Drew, with respect to his developing sense of unit in the contexts of both area and volume across Grades 2 through 5.

Drew gained sophistication in his thinking with respect to unit across area and volume measurement contexts; however, his longitudinal growth was gradual. By closely studying Drew's evolving sense of unit for both area and volume, we gained insights into how concepts related to unit develop over time and across domains of measurement, especially for students who may struggle to coordinate area and volume.

Theoretical Framework

Our research team conducted a longitudinal study of the development of children's spatial measurement concepts across Grades 2 through 5 from a hierarchic interactionalist perspective (Clements & Sarama, 2007), which is a theoretical framework that synthesizes empiricism, (neo)nativism, and interactionalism. At the core of Sarama and Clements' (2009) theoretical and empirical frameworks are hypothetical learning trajectories (LTs). An LT consists of three components: 1) a specific learning goal in a mathematical content domain, 2) a likely path for

learning, and 3) the instructional tasks specifically designed to engender the mental processes or actions that move students along that path (Sarama & Clements, 2009).

Purpose

The purpose of the longitudinal study was to refine and revise LTs for length, area, and volume measurement. Specifically, we posed the question: How do students develop coherent knowledge and integrated strategies for measurement across the developmental span from Grade 2 through 5? The goal of this paper is to describe how children's concepts of units develop across contexts of area and volume from Grade 2 through 5 by focusing on Drew as a case study.

Methodology

This report focuses on one participant (who is a member of a larger sample of 16 children) at a public school in the Midwest. The data was collected between March of 2008 and May of 2011 within the context of a four-year, longitudinal teaching experiment (Steffe & Thompson, 2000). We used previously developed LTs (Sarama & Clements, 2009) to inform our task development and data analysis as we aimed to investigate children's conceptions of spatial measurement across Grades 2 to 5. Results are drawn from semi-structured interviews of approximately 20 to 30 minutes in length and one open-response assessment. Each interview was videotaped, transcribed, and later analyzed according to the LTs. At the conclusion of the data collection, retrospective analyses were conducted, and longitudinal accounts of growth were generated.

Results and Discussion

During the four-year teaching experiment, the research team posed 55 area tasks within 15 interviews and 48 volume tasks in 11 interviews. This report focuses on an illustrative subset of these tasks, as well as from a 33-item open-response assessment to demonstrate Drew's longitudinal growth across area and volume.

Grade 2: Initial Assessment

In the Spring of Grade 2, the research team administered an open-response assessment designed to elicit his ways of identifying and operating on units across area and volume contexts. For one of the area items, Drew was shown an image of a rectangle printed next to a square unit and asked to draw how it would look if he had a whole bunch of those squares to cover the rectangle. He drew 10 individual squares along two rows of the top of the rectangle and said, "just like that to fill it up" (Figure 1). When asked how many he thought he would need to cover the rectangle, he said "20." Drew did not need to complete his drawing; he was able to imagine repeating square units of area to cover the rectangle.

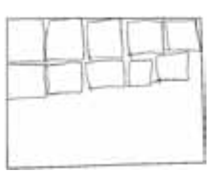

Figure 1: Drew's Drawing

Figure 2: Inch Cube and 2 x 3 x 2 in. Prism

To get a sense of Drew's attention to unit in the context of volume measurement, the interviewer gave him an inch cube and a 2 x 3 x 2 in. rectangular prism and asked how many cubes would be as big as the (2 x 3 x 2) block of wood (Figure 2). Drew, tapped the inch cube on the visible squares on all of the faces of the rectangular prism (turning it to touch all of the

squares on all of the faces) and answered "25." Although he had both the cube and the rectangular prism in his hands, he attended to squares on the faces rather than cubes in his count.

In Grade 2, Drew's unit concepts in an area measurement context were more sophisticated than his unit concepts in volume measurement. His representation (drawing) for the tiling of a rectangle had some errors of alignment, his rows contained the same number of units, and he drew individual approximately the same size squares one-by-one (Figure 1). This suggests that Drew was thinking about repeating individual units of area (without considering composite units). In the context of volume measurement, however, the salient attribute of the rectangular prism was the squares on the faces. Although he correctly identified the square as the appropriate unit for area, he did not seem to identify the cube as the unit of measure for volume on the initial assessment. Drew's nascent sense of unit observed here on the initial assessment evolved to become more sophisticated in Grade 3 in the contexts of both area and volume measurement.

Grade 3

During the Spring of Grade 3, Drew was presented with a 2 x 2 in. square (Figure 3) and asked to find the area. Drew said, "I can't solve the area because in our math boxes in our math books, there's like boxes so we count the boxes." He was then given a 3 x 4 in. rectangle and asked what kind of tool he needed to be able to find the area. He said he needed "a ruler, I think." He placed the ruler along the 4-in. side and noted it was 10 cm. He then placed the ruler along the adjacent side and used the numbered tick marks on the ruler to guide his drawing of tick marks (Figure 4). Drew explained that he used centimeters (as opposed to making use of the given number labels) because the boxes in his math books are about 1 centimeter tall and wide. He explained, "there's a row of boxes between each one, so 10, 20, 30, 40, 50, 60, 70." When asked to draw one of the 70, he drew a row of 10 by extending a single line across the rectangle and used the numbered tick marks on the ruler to guide his placement of segments to subdivide the row into 10 square centimeters. Drew constructed a composite unit and mentally operated on it to determine the area of the 3 x 4 in. rectangle.

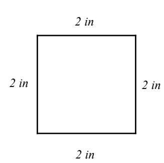

Figure 3: 2 x 2 in. square

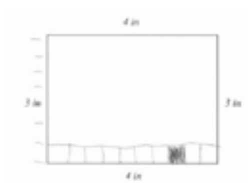

Figure 4: Drew's drawing

Figure 5: Prisms *a*, *b*, and *c*

Also in the Spring of Grade 3, Drew was presented with a task involving unit ratio comparisons and capacity. After comparing prism *a* to *b* and *b* to *c* by pouring water (Figure 5), he said he "figured out a pattern." Drew explained, "it would take two (prism *a*) to get into this one (prism *b*), and two of these (prism *b*) to get into that one (prism *c*)." The interviewer asked, if this (prism *a*) is one, what is this one (prism *b*)? Drew correctly said two. The interviewer then asked, if this (prism *a*) is one, what is this one (prism *c*)? He incorrectly said three. Drew explained that he thought the answer was three "because that (prism *a*) would fill up two (prism *b*); that's (prism *c*) a unit bigger and that would fill up three." Rather than compare the prisms based on reference to a unit, he ranked them in order from smallest to largest by capacity.

In Grade 3, Drew's thinking about unit in area measurement was influenced by the tasks he had seen in his math book that involved counting squares that looked like square centimeters in gridded rectangles. When using the ruler to help him determine the area of the 4 x 3 in. rectangle, he attended to two dimensions and related linear centimeters to square centimeter units of area,

but did not make use of existing number labels (Figure 5). He did not need to draw the entire array in order to operate on composite units (a row of 10) by skip counting; this is the first time we saw Drew think about repeating composite units in a systematic way.

In terms of capacity (Figure 5), his ability to identify and operate on units was limited to situations involving simple doubling. He recognized a one to two ratio for pairs of prisms (a:b is two and b:c is two), but generalized this "pattern" to an ordinal ranking when comparing three prisms (a:b is two and b:c is two, so a:c is three). That is, he did not make ratio comparisons based on reference to a unit when comparing three prisms simultaneously. Drew showed more sophisticated sense of unit in area, attending to composite units, than he did in volume in Grade 3.

Grade 4

Grade 4 was a time for important shifts in his ways of thinking about units for both area and volume. During the Fall of Grade 4 Drew was presented with an image of a 1 x 3 unit rectangle and a rectilinear figure (Figure 6) and asked, "How many grey tiles would fit inside this one (the rectilinear figure)." Drew said, "the top is nine units, and the…all the way across…not like up and down…so you can fit three units on the top…" He discussed first covering the bottom, left and right sides, and then the middle. The interviewer asked him to draw some of the units (Figure 7). Drew then explained, "I kind of just did three across the whole thing and then one, two, three, four, five," pointing to each of the five drawn units in a column. He then traced with his fingers (Figure 8) to indicate the placement of five columns of five units, using the width of his fingers to guide the placement of these columns, saying "one, two, three, four, five…five times five is 25." Once he realized the column structure, he used multiplication to curtail his process of counting by composite units (columns) to structure the rectilinear region.

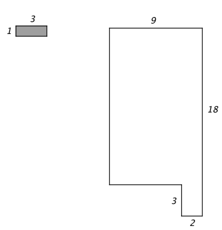

Figure 6: Rectangular Tile Task

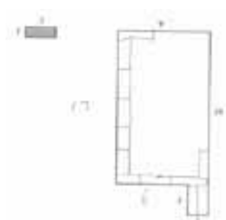

Figure 7: Drew's Drawing

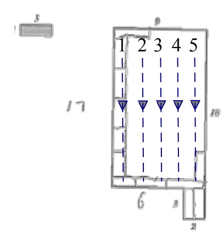

Figure 8: Drew's Finger Tracing

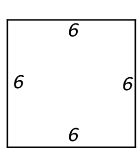
Two months later Drew was provided with an image of a 6 x 6 unit square and asked to determine the area (Figure 9). He traced around the square inside the boundary and explained, "I was trying to do it like painting around the outside first…so that would be like 24 centimeters already…" He went on tracing and explaining "half of 24 is 12…so 24 plus 12 is 36 I think…and then half of 12 would be 6…so 42…and then half of 6 would be 3…so that would be 45...and I think maybe it would cover it all up by then." Figure 10 illustrates Drew's border strategy, or "painting," as indicated by his finger tracing. He imagined square "ring" composites of area units with each successive becoming repeatedly smaller (by half). He was thinking about repeating composites that were the same shape, but not the same size in terms of the number of units.



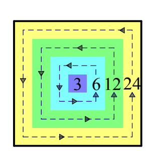


Figure 9: 6 by 6 Unit Square Task

Figure 10: Drew's Border Strategy for Area

One week later Drew again applied his border strategy when comparing a 5 x 8 unit rectangle with a 4 x 9 unit rectangle by area (with linear dimensions indicated by tick marks). He counted around the border of each rectangle to determine the number of square units needed to cover just inside the border and divided this number in half to determine the number of units needed to cover the middle. He explained that this was just one way of finding area and that he could also multiply the length and the width. For Drew, the border strategy and multiplying length by width were two unrelated methods for determining area. Based on his discussion of this task, he did not relate the multiplication of length by width to a structuring of the rectangles by composite units.

During the early Spring of Grade 4 Drew was presented with the images of a net and an open top box (Figure 11). The interviewer explained that the net could be made by cutting along the edges of the box and flattening it and asked, "How many cubes would it take to fill this box? Drew pointed and counted the cubes on the bottom of the net one-by-one in columns in an 'S' pattern (Figure 11). He explained that he needed three "stacks" of 24 or 24 times 3 to fill the box. That is, he operated on a composite unit, a layer, using multiplication to determine the number of cubes that he would need to fill the box.

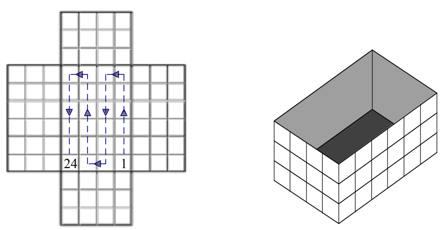

Figure 11: Net and Box

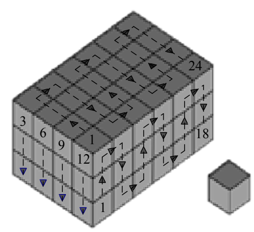

Figure 12: Border Strategy for Volume

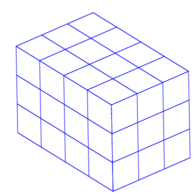

Figure 13: 4 x 3 x 3 Prism

During the same interview, he was presented with an image of a 4 x 6 x 3 unit rectangular prism printed next to a unit cube (Figure 12) and asked, "How many of these blocks (pointing to the unit cube) would it take to make that (pointing to the 4 x 6 x 3)?" Drew counted all of the visible cubes on the front "wall" one-by-one in columns to get 18 cubes. He explained that there were another 18 blocks on the opposite side that he could not see. He then skip counted by threes, saying "three, six, nine, twelve" to determine the number of cubes on the adjacent "wall," and explained that there were 12 more cubes in another "wall" that he could not see. He multiplied 18 by 2 to get 36 and 12 by 2 to get 24 and added 36 + 24 = 60. He then counted the visible squares on the top of the figure one-by-one in rows to get 24. He added the 24 to 60 to find 84. When the interviewer asked him how he got his answer, he explained that he had counted the whole thing, but then decided that he had double counted some of the blocks. He said he thought that he should not have counted the top, so he decided that the first part of his answer, which was 60 was correct; however, he said he could not remember how he got 60. Drew's ways of operating on units in the context of volume changed according to task representation. Without the perceptual support of the net and an open-top box to imagine filling up, Drew attended to individual units on the faces of the rectangular prism rather than composite units (layers).

Five months later, Drew was presented with an image of a gridded 4 x 3 x 3 unit rectangular prism (Figure 13) and the interviewer asked, "How many small cubes like the one shown are in this large block?" Drew said, "I'm going to try a different way," which he clarified to mean that

he was not going to count each unit individually. He counted 12 visible squares on the 4 x 3 face and 9 visible squares on the adjacent 3 x 3 face and multiplied 12 by 9, and when he was asked how he knew to multiply 12 by 9 he said, "I heard of that method kind of…it's usually with tiles, though." The interviewer replied that she had heard of that method for area and asked if he thought the same thing would work here. Drew said, "I think so." When asked if he thought 108 fit there, he said "um…no…it doesn't look like it" and said he thought it looked like it should be less. Drew's application of multiplication here was not connected to a structuring of the rectangular prism by iterating composites (layers).

During Grade 4 Drew exhibited variability in his ways of thinking about units in both area and volume measurement contexts. He operated on composite units using multiplication for some area and volume measurement tasks. This notion of multiplication is repeated addition. Although he operated on a column as a composite unit using multiplication in an area measurement task (Figure 8), he did not consistently relate linear and area units (Kara, Eames, Miller, Cullen, & Barrett, 2011). That is, he did not consistently apply the concept that the length of a side determines the number of area units that fit along the side. As his sense of a composite evolved throughout Grade 4, he generalized his operations on units in an alternative way. For example, he invented the border strategy (Figure 10) as an alternative to multiplying length by width when determining the area of a rectangle. His willingness to suggest that multiplying length by width would give the same answer as his border strategy suggests that he did not seem to see a conceptual link between his use of multiplication to model the mental iteration of a composite unit (as depicted in Figure 8) and the multiplication of length by width.

Drew extended his alterative way of operating on units in area measurement contexts into contexts involving volume during Grade 4. For example, his attention to surface area (Figure 12) seemed to be an extension of his border strategy (Figure 10) from area to volume. At the end of Grade 4, he adapted his multiplication of length by width strategy for area to make sense for him in the context of volume measurement. Instead of multiplying lengths of perpendicular adjacent sides to produce a measure of area, he multiplied surface areas of perpendicular adjacent faces to produce a measure of volume. The variability in Drew's strategy use in Grade 4 (operating on composite, counting around the border, and using multiplication) suggests that his unit concepts were still under development in both area and volume measurement contexts at this time.

Grade 5

Ten months later, during the Fall of Grade 5, Drew was given a 5 x 7 in. rectangle and asked to compare the area of the tile to the area of the larger rectangle. He noted, "5 of these would take up the side rows (pointing to the left and rightmost columns)…and…um…7 of these would take up the longer (pointing to a bottom row of 7)." He then said that the larger rectangle was 35 times bigger than the unit. When asked how he knew that multiplication would tell him how many units would fill the rectangle, he said, "I don't know…I just kinda learned it." The interviewer asked him to draw units, and he drew a column of 5 on the right-hand-side, using the unit tick marks on the ruler to guide his placement of units. Before completing his drawing, he expressed doubt that his answer of 35 obtained by multiplying was correct because he noticed that the corner tiles "took up two spaces." To check, he finished drawing around the border and then covered the interior by drawing the squares by columns. After he finished his drawing he began counting the units one-by-one in the same pattern he described in his tracing in Grade 4 (Figure 15). While counting, Drew suddenly noted that there were five tiles in a column and switched to counting by 5s saying, "5, 10, 15, 20, 25, 30, 35." He realized that counting by columns produced the same answer as multiplying five by seven.

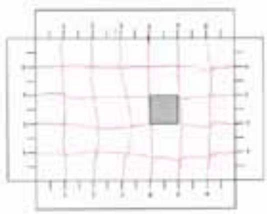

Figure 14: 5 x 7 in. Rectangle

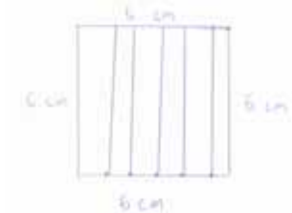

Figure 15: Drew's Rectangle

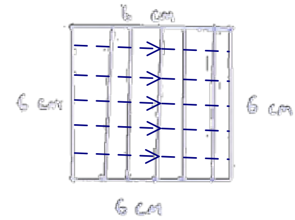

Figure 16: Drew's Gestures

During the Spring of Grade 5, Drew was asked to use a ruler to draw a rectangle with an area of 36 square centimeters. Drew explained that he would have to think backwards from the area formula, and used the ruler to draw the border of a 6 x 6 cm square. After creating his drawing, he said that he thought his square might have too many units. He checked by lining up the ruler with one side and using the numbered tick marks to guide the placement of parallel column line segments (Figure 15). The interviewer interrupted him and asked if he still thought that his square had too many units. Drew gestured with his hand where the parallel row segments would intersect the column segments to form a rectangular array structure of identical square units (Figure 16). He explained that the square has six columns of six square centimeters and six rows of six square centimeters. In the context of this task Drew connected the multiplication of length by width to the structuring of the square with composite units (rows and columns).

Two weeks later, Drew was presented with a wrapped rectangular prism and an inch cube (Figure 17) and he was asked to compare the volume of the inch cube to the volume of prism.

Figure 17: Wrapped Rectangular Prism and Inch Cube

He iterated the inch cube along the length, width, and height of the prism and found that the dimensions were 4 x 3 x 3 in. He said, "I think to find the volume what you're gonna want to do is the width times the height times the length." He noted that 3 times 4 is 12 and 12 times 3 is 36. When asked to draw where 12 would go, he drew a row of 4 on the 4 x 3 in. side and explained that the side would contain three rows of four. For the adjacent 3 x 3 in. side, he drew one unit in the corner and said, "three times three so it would take 9 blocks to fill this side." For the total, he said he would need to do 12 times 9, which the interviewer told him was 108. He then said, "it wouldn't take up 108…I think it will take up 36." To explain his answer, he said "I did 4 times 3 times 3…36…so that's the width times the height times the length." The interviewer drew his attention back to the 4 in x 3 in side by asking how many 12s there were. Drew pointed to the 4 x 3 in. side and explained, "[it would take] 12 blocks to fill that…and then 3 to fill that side…it was actually 9…but the width would be 3 so it would be 3 times 4 times 3...it just goes back to the length times width times height." Although Drew trusted his answer from multiplying length by width by height, he did not clearly connect his application of multiplication by the structuring of the rectangular prism by composite units (layers).

Drew abandoned his border strategy early in Grade 5 because realized that multiplying length by width was the same as operating on a composite unit by skip counting for area (Figure 14). He consistently related linear and area units and used this relationship to develop a drawing strategy for checking his thinking when multiplying length by width. He used the numbered tick marks on a ruler to guide his drawing of parallel row and column line segments to produce a grid so that he could check to see if multiplying length by width produced the correct answer (Figures 15 and 16). He also realized that his adaptation of multiplying length by width for volume (as the multiplication of areas of perpendicular adjacent faces) did not produce the same answer as the multiplication of length by width by height. During Grade 5, Drew showed evidence that he learned that multiplication *does* produce a measure of area or volume; however, he may not yet have understood *why* multiplication produces a measure of area or volume.

Conclusions and Implications

Drew gained sophistication for measuring space more slowly than the other six students in this cohort, perhaps because he sought to systematize his ways of operating on composite units in alternative ways. However, the results of this longitudinal work, which are consistent with prior cross-sectional research (Battista & Clements, 1996; Battista, Clements, Arnoff, Battista, & Borrow, 1998; Outhred & Mitchelmore, 2000), indicate that Drew's understanding of the conceptual link between the iteration of a composite unit and the application of multiplication in both area and volume measurement did increase from Grade 3 to Grade 5. We believe it is important to note that Drew exhibited growth in terms of his use of unit in an area measurement context; and this often precipitated growth in volume measurement. In the current Common Core State Standards for Mathematics, measuring areas of rectangles is introduced and mastered in Grade 3 and measuring volume of rectangular prisms is introduced and mastered in Grade 5. This study adds to the body of research that suggests introducing and mastering these concepts in a single grade level may not be developmentally appropriate for children. Therefore, we recommend providing early experiences for children to think about building and operating on composite units before and during instruction of formulas in a broad time span. Furthermore, Drew's thinking in terms of unit in both area and volume varied in different task representations and use of tools. We suggest that during the instruction of area and volume measurement, tasks should vary in terms of representation.

HOW ARE GEOMETRIC PROOF PROBLEMS PRESENTED? CONCEPTUALIZING AND MEASURING TEACHERS' RECOGNITION OF THE DIAGRAMMATIC REGISTER

Patricio Herbst	Karl W. Kosko	Justin K. Dimmel
University of Michigan	Kent State University	University of Michigan
pgherbst@umich.edu	kkosko1@kent.edu	jkdimmel@umich.edu

We describe the development of measures of teachers' recognition of an instructional norm—that proof problems in high school geometry are presented in a diagrammatic register. A first instrument required participants to openly respond to depictions of classroom scenarios in which the norm was breached. A second instrument was a survey that required participants to rate the extent to which they agreed with various explicit statements about instruction. A third instrument capitalized on pros of the other two. We demonstrate how this instrument development process improved our conceptualization of the components included in the diagrammatic register norm.

Keywords: Geometry and Geometrical and Spatial Thinking, Instructional activities and practices, Measurement, Reasoning and Proof

We describe the process of conceptualizing a norm of instruction and measuring its recognition by teachers. The paper illustrates how the process of improving the instruments led to an improved conceptualization of the construct being measured. Weiss and Herbst (2007) had observed that while theorems are often stated in geometry textbooks using a *conceptual* register (referring to mathematical objects by their names, e.g., base angles, diagonals), proof problems often use a *diagrammatic* register, whereby the 'givens' and the 'prove' are stated in terms of specific objects in a diagram (i.e., using their labels). Moreover, diagrams may add information not stated as "givens" that is nonetheless essential to prove the conclusion (these include properties of betweenness, collinearity, concurrency, intersection, orientation, and separation). Our investigation aims at (1) refining the meaning of the statement that proof problems are presented in the diagrammatic register and (2) determining to what extent geometry teachers recognize such presentation as normative.

We build on scholarship that studies social practices and their participants' tacit knowledge (e.g., Bourdieu, 1990; Collins, 2010; Garfinkel & Sacks, 1970). This scholarship offers the notion that practices include regularities that are often tacit even though they are experienced as normative: We call those *norms* and apply that notion to the study of mathematics teaching. Earlier work on the notion of classroom norms (and germane notions such as *cultural script*) has drawn empirical support on detailed analysis of cases of teaching (e.g., Bauersfeld, 1988; Stigler & Hiebert, 1999; Yackel & Cobb, 1996) or on the analysis of practitioners' reactions to cases of instruction (e.g., Jacobs & Morita, 2003; Nachlieli & Herbst, 2009). Scholarship in social psychology (Aarts & Dijkterhuis, 2003; Nolan, et al., 2008) shows examples of how recognition of situational norms can be studied empirically and some of that methodology has percolated to the study of general norms in teaching (Hora & Anderson, 2012). This paper contributes to designing instruments to confirm quantitatively the recognition of norms of instructional situations in mathematics: By instructional situations we mean particular segments of classroom mathematical work that have a taken-as-shared exchange value among the instructional goals at stake in a given course of studies (Herbst, 2006). In this case we focus on the situation of "doing proofs" in which proofs of particular propositions exchange for students' skill at doing proofs.

We focus on the design of instruments to measure recognition of the norm that proof problems are stated in the diagrammatic register. Our initial understanding of what could be meant by *diagrammatic register* was holistic—it referred to relationships between the problem statement and the diagram included. We expected that practitioners would hold that norm tacitly: They would recognize when a proof problem had breached this norm and be able to produce proof problems that complied with the norm, but they would not necessarily be able to say what the norm consists of.

Methods

Initially, we created two kinds of instruments. One, a "tacit norm recognition instrument" (a.k.a., N1), kept the phenomenon at a holistic level, requiring participants to evaluate the work of teacher in classroom scenarios where the teacher posed a proof problem that breached the norm. Scenarios were rendered as image sequences with cartoon characters enacting teacher and students and speech bubbles for their talk. The open ended questions asked participants to describe what they saw happening and to evaluate the teacher's work facilitating the doing of a proof. Four different scenarios were presented to participants (item sets 21002, 21003, 21004, 21006), each of which enacted a breach of the norm in different ways. For example in one scenario the teacher described in writing the figure to which the proof problem referred but did not draw a diagram for it. Participants were told that the scenarios were about doing proofs in geometry but were not told that they included breaches of norms or that there was anything special about the handling of diagrams.

The second instrument, an "explicit norms recognition instrument" (a.k.a., N2), required participants to rate statements that described, in general, possible behaviors of a teacher posing proof problems. Participants had to rate how appropriate and how typical were actions described in statements, such as: "the teacher provides a diagram for students to use while doing a proof". The creation of this instrument gave us a first opportunity of laying out in a more analytic fashion what the "diagrammatic register" norm consisted of. In doing so we proposed five distinct subnorms making up the diagrammatic register. Concisely stated, the initial statements of these subnorms were as follows (construct IDs in brackets): (1) the teacher provides a diagram that has the givens marked when assigning a proof [DP21]; (2) the teacher provides a diagram for students to use while doing the proof [DP24]; (3) the points of the diagram which are needed for the proof (though not necessarily all of the points) are provided and labeled by the teacher [DP36]; (4) the statement of the proof problem uses symbols and labels for the elements of the diagram (e.g., $AB \perp CD$) [DP39]; (5) the diagram the teacher provides accurately represents the concepts at stake in the proof [DP41].

To examine responses to N1 we created a coding scheme that assessed open responses for evidence that participants recognized breaches of the diagrammatic register norm and for evidence of whether participants appraised the teaching negatively. Reliability was established by having two independent coders code through responses and resolve disagreements on a case-by-case basis. To examine internal reliability of constructs in the N2 instrument, we implemented classical item analysis (CIA; see Crocker & Algina, 2006).

Data Sources and Analysis

The N1 instrument was piloted with 50 teachers including 33 that had three or more years of experience teaching geometry (EGT) and 17 teachers without such experience (thus including novices as well as teachers experienced teaching other courses). The N2 instrument was piloted with 44 teachers including 28 EGT and 16 teachers without such experience. Table 1 shows how

many participants recognized the breaching of the diagrammatic register norm in each of the N1 stories. Across items, experienced geometry teachers had higher totals for recognition of the norm. Binomial tests, assuming a null hypothesis that recognition and nonrecognition are equally likely, showed statistically significant results for experienced geometry teachers in story 21002 (p<.05), and 21003 (p<.05), while for these same items the other participants showed no significant difference from chance in their rate of recognition of the norm.

Table 1: Number of Teachers Who Recognized Breach of the Norm

	21002	21003	21004	21006
Exp. geometry teachers (>3 years)	18	18	11	5
Other teachers	7	10	4	3
Total	25	28	15	8

Responses were also coded for the presence of negative appraisals (Martin & White, 2007) of the depicted teaching. We defined the variable "discomfort with the scenario" to capture participants' critiques not sufficiently focused to count as recognitions of the norm. For example, "discomfort" captured entries where participants critiqued that the teacher "did not write anything down." "Discomfort" and "norm recognition" are mutually exclusive—only participants that did not recognize the norm were coded for having discomfort with the scenario. Table 2 shows the aggregate of those participants that either recognized the norm or registered discomfort with the teaching.

Table 2: Aggregate Proportion of Participants that Recognized the Norm and Participants that Registered Some Discomfort with Each Scenario

	21002	21003	21004	21006
Exp. geometry teachers (>3 yrs.)	30	29	17	24
Other teachers	10	14	6	14
Total	40	43	23	38

The data suggests that participants may be reacting negatively to the scenario in ways that are not localized around the breach of the norm and the specific features of the diagrammatic register. Indeed, even among participants that did recognize the norm, that recognition was not always focused on features commensurate with the subnorms identified above. Those results were not surprising on account of our hypothesis that the diagrammatic register norm is tacit: Unlike other norms in "doing proofs"—such as the norm that every statement must be justified by a reason (Nachlieli & Herbst, 2009)—the norm that problems are presented in the diagrammatic register is not explicitly addressed in the work of teaching. Earlier work in ethnomethodology suggested that when such implicit norms are breached, participants engage in repair strategies—ways of signaling that something is amiss—though these strategies do not always include pointing at what was amiss (e.g., reframing the activity as a case of a different situation).

This lack of specific reference to the features of the register within the open responses was the principal motivation that led us to conceive of a new instrument (N3, described below) to

study the diagrammatic register. It seemed that, since the subnorms of the diagrammatic register are tacitly held, testing for these subnorms via open response prompts placed too onerous a reporting burden on the participant. If participants did not comment on specifics of how problems were stated this could mean that participants did not know how to focus their reaction—an explanation that coheres with the hypothesis that the norm is tacit. The other reason that called for developing N3 came from the analysis of pilot data on N2.

Participants made two ratings of each of the N2 statements: An appropriateness rating—this was a 6-valued rating scale, ranging from "Very Inappropriate" to "Very Appropriate"—and a typicality rating—this was a 4-valued rating scale that ranged from "It Never or Hardly Ever Happens" to "It Always or Almost Always Happens". The two kinds of questions aimed at complementary aspects of normativity (appropriateness and frequency) so we examined their internal reliability separately.

Table 3: Reliability for the N2 Constructs.

Construct	Reliability for "Appropriateness" Scale	Reliability for "Typicality" Scale
DP21 [Givens marked]	$\alpha = .78$	$\alpha = .61$
DP24 [Diagram provided]	$\alpha = -.02$	$\alpha = -.06$
DP36 [Labeled points]	$\alpha = .50$	$\alpha = .70$
DP39 [Statement uses labels]	$\alpha = -.37$	$\alpha = .15$
DP41 [Diagram Accuracy]	$r = .40$	$r = .33$

Table 3 shows results of the item analysis for the responses to the N2 item, indicating reliability for some constructs (DP21, DP36, DP41) but not for others (DP24, DP39). DP41 had only two items, so while alpha was not calculated, responses to both items showed moderate correlations. For DP39, items generally performed poorly unless recoded to assume the norm was that all points had to be labeled, and not just the ones relevant for a proof (in which the alphas improved to over .70 for each scale).

Table 4: Correlations with Experience Teaching Geometry for Appropriateness and Typicality

	DP21		DP24		DP36		DP39		DP41	
	App	Typ	App	Typ	App	Typ	App	Typ	App	Typ
Taught >3 years Geometry	-.04	.05	.03	.08	-.36*	-.26[a]	.08	.20	-.09	-.05
Taught ≥ 1 year Geometry	-.27[a]	.12	.02	-.12	-.36*	.19	.07	.23	-.19	.12

[a] *$p < .10$, *$p < .05$, **$p < .01$*

Note: 'App' and 'Typ' represent correlations for the appropriateness and typicality scales, respectively.

Striving to better understand why the constructs performed the way they did, we looked at how participants answered items, by correlating their status of being an experienced geometry teacher (or not), as well as if they had ever taught geometry (or not) with the construct scores.

These results, shown in Table 4, showed few correlations between the constructs and geometry teaching experience. The only statistically significant correlations were negative, suggesting that participants rejected the explicitly stated norms.

Discussion: Revisions Needed to the Instruments

Several issues were raised by the analysis of the data from the first pilot. First, the results of the first pilot indicated that the N1 instrument was insufficiently sharp: It did not elicit commentary from participants that pointed specifically to the features of the diagrammatic register norm. Another issue with the N1 instrument was that some of the discomfort reported by participants could be attributed to ancillary features of the scenarios—e.g., that the teacher had not written the statement of the problem on the board. In revising scenarios for a second pilot we avoided those confounding elements, but our review of the results from the first pilot also raised issues with the N2 instrument. Specifically, the item analysis from N2 led us to question whether recognition of the diagrammatic register subnorms could be assessed with instruments that asked participants to rate general statements. We also realized that in looking for explicit general statements of the subnorms of the diagrammatic register we had failed to include any indications of what mathematical properties are often communicated through the diagram. In the case of developing scenarios to breach the diagrammatic register norm for the N1 instrument, we had assumed that we should choose problems that involved collinearity, separation, concurrency, or betweenness, and that we should present those problems without using diagrams. But we had failed to include any N2 item that explicitly tested for recognition that such properties are normatively telegraphed by the diagram. As a result, we had created some tacit items (for the N1 instrument) that seemed to lose part of their meaning when made into explicit general statements (for the N2 instrument). The logistical and technical difficulties we had run into when examining the pilot data had led us to realize that there were gaps in our conceptualization of what the subnorms really should be. We had the chance to fill those gaps when we conceptualized a new instrument, one that we refer to as N3.

Table 5: Revised Subnorms of Diagrammatics Register After Initial Piloting

Designation	Subnorm statement
Subnorm 1 (New)	The statement of the problem does not make explicit properties of betweenness, intersection, separation, collinearity, or concurrency, which are left for the diagram to communicate.
Subnorm 2 DP21	The teacher provides a diagram for students to use while doing the proof.
Subnorm 3 DP39	The teacher assigns a proof problem with an accompanying diagram where the points needed in the proof are labeled (but not necessarily all points).
Subnorm 4 DP24	The proof problem is stated using symbols and labels for elements of a diagram (e.g., $AB \perp CD$).
Subnorm 5 DP41	When a teacher provides a diagram accompanying a proof problem, the diagram is accurate.

We drew an analogy to an optometrist trying different lenses on a patient to design a novel format for an item that could blend the contextualization virtues of the N1 instrument (where participants handle a specific proof problem) and the analytic virtues of the N2 instrument

(where it is possible to expose participants to many items and thus be able to do an item analysis). The resulting N3 instrument asks participants "which of the two proof problems below is more appropriate for geometry teachers to present to their students" and offers two problems that differ from each other only in regard to their compliance with or breach of one subnorm of the diagrammatic register. The participant answers using a 6-point scale, with options that include "Option A is much more appropriate" (viz., somewhat more appropriate, slightly more appropriate), and same options for Option B. To concentrate on the norms that had been more problematic when developing N2, we created N3 items that tested the subnorms listed in Table 5.

Table 6. Reliability Measures for Revised Instruments for N2 & N3

Assessed Norms	Reliability (α) for N2 in 2nd Pilot	Reliability (α) for N3 in 2nd Pilot
Subnorm 1: The statement of the problem does not make explicit properties of order, separation, collinearity, or concurrency, which are left to the diagram to communicate.	-.10	.64
Subnorm 2: The teacher provides a diagram for students to use while doing the proof.	.69	.80
Subnorm 3: The teacher assigns a proof problem with an accompanying diagram where the points needed in the proof are labeled (but not necessarily all points).	-.28[1] .61[2]	-.12[1] .69[2]
Subnorm 4: The proof problem is stated using symbols and labels for elements of a diagram (e.g., $AB \perp CD$).	.63	.77
Subnorm 5: When a teacher provides a diagram accompanying a proof problem, this diagram is accurate.	.55	.82

[1]*Assumes the norm of "only points relevant to completing the proof are labeled."*
[2]*Assumes the norm of "all points on the diagram are labeled."*

This N3 instrument, along with a revised version of the N2 instrument (whose revisions were a consequence of the further articulation of the subnorms described above), was piloted during three data collection sessions in May and June of 2012. Forty-nine participants completed the revised N2 instrument, while 52 participants completed the N3 instrument. This second round of piloting showed higher validation scores than in the first pilot, as reported in Table 6. Still, while the data showed improvement in the reliabilities for four of the subnorms in the revised N2 compared to its first version, N2 was still not effective assessing recognition of the first subnorm. Overall, while not completely successful, N3 is providing more reliable estimations of participants' recognition of the subnorms that constitute the diagrammatic register. (Incidentally,

note that in the second pilot we did not test for recognition of DP 21, the norm that givens are marked, because that one had achieved acceptable alpha levels in the first pilot.)

The N1 instrument was also revised to sharpen the scenarios. One scenario (21004) was withdrawn and two new ones were included (21005 and 21007). Additionally, the questions in each item set were revised. For each scenario, participants were first asked to describe what they saw happening. Then they were asked to rate, on a 6-point scale, how appropriate the teacher's facilitation of the work on a proof was and they were given a box to explain their rating. Finally they were asked to rate, on a 6-point scale, how appropriate the description of the proof problem assigned to the class was and they were given a box to explain their rating. As in the case of the first pilot, we coded the open response questions for evidence of recognition of a breach of the norm and for evidence of discomfort with the scenario. We defined the aggregates "Norm recognition" (NR) and "Repair" (RP) as follows: For each item set *j*, participants were assigned a 1 for NR(*j*) if at least one of the open responses contained evidence that the participant had noticed a breach in a specific subnorm of the diagrammatic register; participants were assigned a 1 for RP(*j*) if they had a 1 for NR or if in at least one of the open responses they indicated discomfort with the teaching represented in the scenario. Reliability for this coding was very good, as attested by kappa values reported in Table 7. The table also contains basic counts of these variables for the whole sample, along with their significance, assessed using binomial tests against a null hypothesis that recognition or non-recognition of a breach in or a repair to the scenario occurred with equal probability.

Table 7: NR(j) and RP(j) Totals per Session for Second N1 Pilot Study, with Kappa (κ) Statistics for Reliability, and with Binomial Probabilities

Session		NR(*j*)			RP(*j*)		
	n	Total	κ	*p*	Total	κ	*p*
21002	42	32	0.77**	0.0003	37	0.82**	<0.001
21003	39	23	0.78*	0.0686	29	0.77**	<0.001
21005	39	22	0.87*	0.0928	34	0.94**	<0.001
21006	40	17	0.86*	0.0689	30	0.95**	0.001
21007	42	18	0.95*	0.0804	28	0.86**	0.012

**Indicates results that are significant at the .10 level*
***Indicate results that are significant at the .05 level*

These results of the binomial tests reported in Table 7 show that overall participants recognized the breach of the tacit norm in these items at a probability that differed significantly from what would be expected from chance alone. In this respect, item 21002 is set apart from the other breaching items. One reason that could explain this difference is that the classroom story prompt for item 21002 depicted the teacher breaching the tacit norm without an apparent reason for having done so. Whereas in the other items, while the depicted teacher still breaches the norm, in each of these instances there were—by design—mitigating factors suggested by the scenario that could have accounted for the teacher's departure from the norm, such as a teacher's wish to emphasize the conceptual (rather than diagrammatic) statements of particular geometry concepts. The fact that participants offered repairs to the scenario for each of the breach items suggests that even though participants were not as likely to recognize a specific breach in items

21003-21007, they still noticed that something was amiss in some way. Thus, it seems that this set of items is effective detecting teachers' recognition of the diagrammatic register norm.

Conclusion

The development of instruments to measure teachers' recognition of an instructional norm moves our work forward in the study of a phenomenon that is specific to mathematics teaching—i.e., specific to the work of teaching, and specific to the mathematics at play. We contend that this work is also valuable insofar as it illustrates a process of discovery in our field: A dialectics of conceptualization and measurement in the research process that challenges the received wisdom whereby small scale, qualitative, exploratory studies provide sufficient material for theoretical conceptualization while larger scale, quantitative studies are needed only eventually and just to verify or falsify theoretical assertions. Consistent with contemporary views on measurement (e.g., Wilson, 2005), the study shows how the goal of measurement and the analysis of a relatively large set of responses to initial instruments led to further conceptualization of the theoretical construct we wanted to confirm, revise the instruments to actually measure this construct, and obtain results that allow us to report on the extent to which the hypothesized construct was present.

SUPPORTING TEACHERS' AND STUDENTS' KNOWLEDGE OF GEOMETRIC SIMILARITY

Nanette Seago
WestEd
nseago@wested.org

The main goal of the Learning and Teaching Geometry (LTG) project is to build professional development (PD) materials that provide opportunities for teachers to engage in learning about geometric similarity through the use of video cases, in which specific and increasingly complex mathematical ideas are presented within the dynamics of classroom practice. The central component of the LTG materials is the Foundation Module, which includes 30 hours of PD and is intended to provide teachers with a thorough grounding in key mathematical and pedagogical issues related to similarity. Field test data indicate that the Foundation Module supports gains in both teachers' and students' knowledge of similarity.

Keywords: Geometry, Mathematical Knowledge for Teaching, Teacher Education-Inservice/Professional Development, Teacher Knowledge

Introduction

Research has provided emerging evidence that certain characteristics of PD are important for influencing changes in classroom practice and supporting student achievement (Heck, Banilower, Weiss & Rosenberg, 2008; Sample McMeeking, Orsi & Cobb, 2012). For example, programs with a focus on subject matter knowledge and student learning in that subject are more likely to have an impact on student achievement than those focused on more generic topics (Cohen & Hill, 2000). In addition, numerous studies examining the effectiveness of mathematics and science PD have found that teachers who participated in activities that emphasized content knowledge, active learning, and coherence were more likely to report enhanced knowledge along with changes in their teaching practice compared to teachers who did not participate in such programs (Garet, Porter, Desimone, Birmin & Yoon, 2001).

There is strong evidence that best practices for mathematics PD include providing teachers with learning opportunities that are intensive in focus and extensive in duration (Garet et al., 2001) and that are "practice-based"—that is, they enable teachers to examine the mathematical skills and understanding that undergird their classroom curriculum, investigate students' mathematical thinking, and explore instructional practices that support student learning (Ball & Cohen, 1999; Cohen & Hill, 2000). By focusing on developing the understanding, skills, and dispositions that teachers use in daily practice, "practice-based" PD provides a meaningful context for teachers' learning.

Video can be an effective PD tool, as it brings the everyday work of teaching into a professional learning environment. Just as curriculum does not stand alone in classrooms, video does not stand alone in PD. Organizing PD around the study of videos does not, in itself, guarantee significant teacher learning any more than the use of technology in the classroom ensures that students will develop deep understandings. Like technology, videos are only tools; professional developers must help teacher educators use these tools to achieve specific learning goals. Without guidance, such as an analytic framework and explicit tasks, teachers watching videos rarely address subject matter content (Castro, Clark, Jacobs, & Givvin, 2005). Knowing how to observe teaching, what to look for and what to focus on, and how to talk about what one

sees are important skills to be learned (Castro, 2005). Learning these skills helps teachers to more skillfully "see" the subject matter in lessons, discriminate ways that learners comprehend subject matter; identify problematic features; assess student responses; detect, diagnose, and develop instructional responses to student errors; and generally gain more insights into their own practice (Givvin, 2005).

Theoretical Framework for the Learning and Teaching Geometry Project

The main goal of the Learning and Teaching Geometry (LTG) project is to build professional development materials that provide opportunities for teachers to expand their mathematical knowledge for teaching. The LTG PD materials help teachers to meet the challenges of teaching geometric similarity in accordance with the Common Core State Standards, which require defining and applying similarity based on geometric transformations—an approach that is likely to be new to most teachers and students.

The theoretical frame for the project is adapted from the work of Deborah Ball and colleagues (Cohen, Raudenbush & Ball, 2003) that incorporates research on both teaching and learning. As depicted in Figure 1, the content of the video case materials focus on the interactions between the teacher, the content (in this case, similarity tasks), and the students, within the context of an authentic classroom environment. The materials are designed to be used by a teacher educator who is faced with a similar set of relationships: the interactions between the teacher educator, the content (in this case, teaching and learning of geometric similarity), and the teachers with whom he or she works. The LTG Study is based on the premise that both classroom learning and professional learning opportunities are a function of these reciprocal relationships.

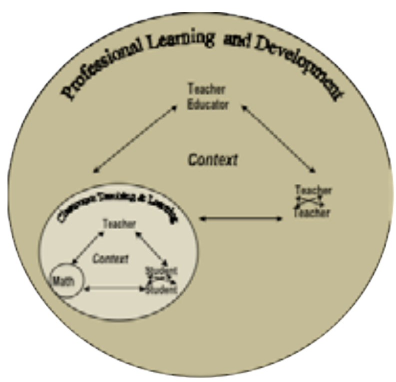

Figure 1: Theoretical Framework (Adapted from Cohen, Raudenbush & Ball, 2003)

The Learning and Teaching Geometry PD Materials

The LTG PD materials are intended for use in the professional development of mathematics teachers serving grades 5-10. Some of the videocases portray student thinking about particular concepts and some videocases portray pedagogical strategies and their impact on students' opportunities to learn (Seago, Driscoll & Jacobs, 2010). The materials follow a learning trajectory that is designed to enrich teachers' MKT as well as their ability to support students' understanding of similarity in alignment with the Common Core State Standards for mathematics. Specifically, they encourage teachers to gain a robust conception of similar figures as part of an infinite family that can be formed by applying one or more geometric transformations. Figure 2 illustrates the mathematical storyline in the Foundation Module, noting the central mathematical focus within and across sessions. The Foundation Module consists of

10, 3-hour sessions that are intended to provide teachers with a thorough grounding in key mathematical and pedagogical issues related to similarity.

Session 1	Session 2	Session 3	Session 4	Session 5	Session 6	Session 7	Session 8	Session 9	Session 10
A dynamic, transformational view of congruence	A dynamic, transformational view of similarity	Relationship between dilation and similarity	Properties of dilation	Preservation of angles & proportional lengths through dilation	Ratios within & between similar figures	Ratios within & between similar figures, Part 2	Connect-ions between similarity and slope & linearity	Area of similar figures	Closure and re-capping of big ideas
Defining Congruence and Similarity			Relationships and Attributes of Similar Figures				Connections		Closure

Figure 2: Mathematical Storyline of the LTG Foundation Module

Each session has at its core one or more digital video clips of a mathematics classroom. These clips are unedited segments selected from classroom footage of un-staged mathematics lessons, representing a range of grade levels, geographic locations and student populations across the United States. The clips offer a window into a variety of issues related to content, student thinking, and pedagogical moves. These clips typically represent a conceptual hurdle or portray some degree of mathematical confusion, based on the expectation that they are likely to provoke inquiry and discussion within the PD setting

Prior to watching a given video clip, teachers' grapple with the same mathematical task(s) the videotaped students tackled. Significant time is devoted to forecasting alternative solutions, comparing solutions, and anticipating student misconceptions. Typical conversations include consideration of: (1) the mathematical skills, procedures, and concepts entailed in the task; (2) the mathematical reasoning and solution strategies (correct and incorrect) that students are likely to apply to the task; (3) the affordances and constraints of different mathematical representations (e.g., pictures, tables, graphs, equations); and (4) instructional moves, such as questions and scaffolds, that might be helpful to support students' learning. Carefully designed focus questions help guide the viewing and analysis of the video clips, and provides teachers' support in unearthing student thinking. The questions and probes that accompany the LTG materials support a deep and substantive examination of classroom interactions.

Field Test Study of the LTG PD materials

Field Test Sites & Implementation

A field test of the LTG Foundation Module was conducted in 8 sites throughout the U.S. by a group of nine experienced facilitators personally recruited by the LTG staff. Most of the facilitators were state- or district-level middle and/or secondary mathematics coordinators, and two were university mathematics or education faculty. The field test was conducted over two academic years (2010-11, 2011-12) and used a treatment and comparison design in order to generate both formative and summative evaluation data related to impacts on teacher and student knowledge. Each facilitator recruited both treatment (87) and comparison (40) teachers. Typically, facilitators asked the treatment teachers to nominate comparison teachers from the same school and grade level.

Measures

To measure the impact of the LTG PD on teachers' mathematical knowledge for teaching in the domain of similarity, Horizon Research, Inc. (HRI) developed three instruments: a multiple-choice assessment, and two assessments embedded within the PD. HRI also developed a student assessment to measure the impact of teachers' participation in the LTG PD on their students' knowledge of similarity.

Teacher multiple-choice assessment. The multiple-choice teacher assessment includes 25 items targeting knowledge in five focus areas: (1) dilation; (2) properties of similarity; (3) ratios and proportions; (4) scaling; and (5) congruence transformations. The items were compiled and modified from released items used in state, national (NAEP), and international (TIMSS) assessment sources. About half of the items are purely content-based; the rest are set in teaching contexts that situate them in the work of teaching geometry. The items were reviewed by the LTG developers to validate them as accurate and appropriate to the content emphasis of the LTG PD materials. Pilot testing conducted as part of the project helped inform revisions to the instrument and demonstrated its sensitivity to teacher engagement with PD based on the LTG materials. The internal consistency of the full multiple-choice assessment was calculated using Cronbach's alpha as 0.81 for the pretest and 0.82 for the posttest.

Embedded assessments. The embedded assessments consist of two tasks that exist within the LTG Foundation Module: a mathematics task and a video analysis task. Both tasks address aspects of MKT, including subject matter content knowledge and pedagogical content knowledge (such as knowledge related to anticipating and interpreting student thinking about similarity). Each task was administered twice during the course of the intervention (first in an early session of the Foundation Module and again in a session near the end of the Foundation Module).

Student multiple-choice assessment. The student assessment contains 20 multiple-choice items and, like the LTG teacher assessment, targets content knowledge in five areas: (1) dilation; (2) properties of similarity; (3) ratios and proportions; (4) scaling; and (5) congruence transformations. Items were drawn from the same sources as the teacher assessment. In addition to review by LTG staff, HRI tested possible items through cognitive interviews with students in grades 7-9. Information gathered from these interviews helped to ensure the items were clear, plausible, and had content validity. Internal consistency reliability of the full student assessment was calculated using Cronbach's alpha as 0.71 for both the pretest and posttest.

Administration and Scoring of Measures

The three teacher knowledge assessments were each administered at two time points to 83 treatment teachers during implementation of the PD. Table 2 identifies the sessions in which the assessments were administered to treatment teachers. The assessments were also administered at two time points to 38 comparison teachers in separate meetings. Facilitators were asked to schedule the administration of assessments to the comparison teacher within the same timeframe as treatment teachers' participation in the PD in order to make data collection from these two groups consistent.

Results

Gains in teachers' geometry content knowledge. Analysis of the teachers' multiple choice assessment scores was conducted using repeated measures ANOVA to test for changes in percent correct scores over time. This approach controls for overall gains in the treatment and comparison teacher groups that may be attributed to learning from a year of teaching practice or from two administrations of the measure.

In the analysis, the main effect of group was non-significant, suggesting that the treatment and comparison teachers were initially comparable. A significant main effect of time (F = 21.09, $p < .05$) demonstrated that, on average, teachers improved from pre- to post-test. A significant time by group interaction term (F = 9.65, $p < .05$) indicated that the change in scores from pre- to post-test varied depending on participation in the treatment or comparison group. The treatment group demonstrated an average gain of 8.73 percentage points from pre- to post-test, whereas the comparison group demonstrated an average gain of 1.68 percentage points (see Table 1). In other words, teachers who experienced the LTG Foundation Module gained, on average, 7.05 more percentage points on their content assessment from pre- to post-test than teachers who did not experience the program. In pooled standard deviation units, the size of this effect was 0.39.

Table 1. Teachers' Geometry Assessment Scores

	Treatment Group (n = 83)		Comparison Group (n = 38)	
	Pre-test	**Post-test**	**Pre-test**	**Post-test**
Mean	**63.66**	**72.39 ***	**65.79**	**67.47**
(sd)	**(17.96)**	**(17.88)**	**(19.48)**	**(17.05)**

* A significant time by group interaction term indicated that treatment teachers demonstrated larger improvements in percent correct scores than comparison teachers (repeated-measures ANOVA; $p < .05$).

Gains in teachers' ability to apply their knowledge to classroom contexts. The mathematics task embedded assessment included three questions about similar rectangles. Questions 1 and 2 asked teachers to provide two different—but correct—methods to solve the same problem. Question 3 asked teachers to provide a method students might use that would lead to an incorrect solution. Scores for each question were analyzed using a Wilcoxon Signed Ranks Test for examining changes from pre- to post-test for each group. The False Discovery Rate adjustment for type I error was used to compensate for multiple comparisons.

Treatment teachers improved in their ability to provide a method, as shown in Table 2. For the treatment group, on average, there was a significant improvement in the scores on Questions 1 and 2 from pre- to post-test (p values < .05). The effect sizes for treatment group gains in scores on these questions were 0.30 and 0.32, respectively. There was not a significant change on Question 3 scores from pre- to post-assessment for treatment teachers. The comparison group, on average, did not demonstrate significant changes in score for any of the three questions.

Table 2. Teachers' Mathematics Task Embedded Assessment Scores

	Treatment Group (n = 82)				Comparison Group (n = 39)			
Question	Pre-test Mean (sd)	Post-test Mean (sd)	Ranks	Effect size	Pre-test Mean (sd)	Post-test Mean (sd)	Ranks	Effect size
1	2.56 (1.42)	3.17 (0.73)	33 + * 36 = 13 –	0.30	2.82 (1.45)	3.18 (1.07)	8 + 28 = 3 –	--
2	1.88 (1.53)	2.73 (1.38)	41 + * 29 = 12 –	0.32	1.95 (1.64)	2.23 (1.40)	16 + 14 = 9 –	--
3	2.73 (1.27)	2.78 (1.12)	27 + 31 = 24 –	--	2.85 (1.31)	2.77 (0.96)	14 + 15 = 10 –	--

[a] Ranks are reported with + indicating the number of teachers showing improvement from pre- to post-test, = indicating teachers with the same score on both administrations, and – indicating teachers with a decline.

- Significant improvement from pre- to post-test scores (Wilcoxon Signed Ranks Tests; p < .05)

The video analysis embedded assessment included three questions, prompting teachers to first interpret, and then apply, a student's approach to solving a similarity problem using dilation. For the comparison group, the Wilcoxon Signed Ranks Test did not reveal significant changes for any of the questions. Table 3 indicates that for the treatment group, on average, there was a significant improvement in the overall scores for all three questions, suggesting improved understanding of mathematical similarity in relation to dilation ($p < .05$ for all questions). The effect sizes for these questions were 0.32, 0.25, and 0.21 respectively.

Table 3. Teachers' Video Analysis Embedded Assessment Scores

	Treatment Group (n = 66) [a]				Comparison Group (n = 39)			
Question	Pre-test Mean (sd)	Post-test Mean (sd)	Ranks	Effect size	Pre-test Mean (sd)	Post-test Mean (sd)	Ranks	Effect size
1	3.89 (2.03)	5.02 (2.21)	39 + * 12 = 15 –	0.32	3.51 (2.61)	4.31 (2.14)	20 + 9 = 10 –	--
2	4.39 (2.55)	5.26 (2.09)	32 + * 16 = 18 –	0.25	3.87 (2.50)	4.38 (2.36)	19 + 5 = 15 –	--
3	2.00 (1.48)	2.56 (1.37)	29 + * 20 = 17 –	0.21	1.97 (1.50)	1.90 (1.50)	16 + 10 = 13 –	--

[a] Data from one field-test site was removed because participants discussed the video analysis task before providing written responses.
* Significant improvement from pre- to post-test scores (Wilcoxon Signed Ranks Tests; $p < .05$)

Gains in students' geometry content knowledge. A three-level hierarchical linear model was used to analyze data collected from students of treatment and comparison group teachers. This approach accounts for the repeated measure and the nested data structure of students in classrooms with the same teacher. A significant effect of time ($t = 5.69$, $p < .05$) indicated that across groups students' scores improved over the course of the year, as would be expected. Adding a time by group interaction term to the analysis revealed a significant difference ($t = 2.31$, $p < .05$) in gains between pre- and post-assessment scores for students of teachers who were engaged with LTG compared to students of teachers who were not involved in the PD (see Table 4). Average pre-post gains for students of treatment group teachers was 6.55 percentage points higher than gains for students of comparison group teachers. The size of this effect was 0.49 pooled standard deviation units.

Table 4. Students' Geometry Assessment Scores

	Treatment Group (n = 162) [a]		Comparison Group (n = 104) [a]	
	Pre-test	**Post-test**	**Pre-test**	**Post-test**
Mean	**36.42**	**45.28 ***	**42.69**	**45.00**
(sd)	**(17.14)**	**(17.15)**	**(17.63)**	**(18.97)**

[a] One treatment student's data and four comparison students' data were not included in the analysis because more than one-third of their item responses were left blank on one or both administrations of the assessment.

* A significant time by group interaction term indicated that students of treatment teachers' demonstrated larger improvements in percent correct scores than students of comparison teachers (repeated-measures ANOVA; $p < 0.05$).

The improvement among students of teachers engaged in LTG appears to have helped these students "catch up" to the students of teachers in the comparison group, whose estimated initial scores were, on average, more than six percentage points higher. In order to explore what changes in performance on the assessment accounted for this improvement, item-level results were examined by comparing the percent of students in the treatment and comparison groups that answered each item correctly on the pre- and post-tests. For 11 of the 20 items, the gain in the percent of students answering the item correctly favored the treatment group by 8 percentage points or more. None of the gains favored the comparison group by more than 5 percentage points. The 11 items with gains favoring the treatment group included all 3 items targeting dilation, 3 of the 4 items targeting congruence transformations, and both items targeting properties of similar figures. In the other two content areas, 2 of 6 items targeting scaling and 1 of 5 targeting ratios favored the treatment group. Although exploratory, these trends suggest that the treatment group students' improvements occurred in the content areas that are especially emphasized in the LTG Foundation Module and, prior to the release of the Common Core State Standards, have been less commonly addressed in middle school curricula (Confrey & Krupa, 2010; Heck, Weiss, & Pasley, 2011).

Discussion

Analyses from the field test study of the LTG PD materials offer evidence of the promise of the Foundation Module for achieving the intended teacher knowledge outcomes, including gains in geometry content knowledge along with the knowledge to apply understandings about content in mathematics instructional practice. These analyses used data from treatment and comparison teacher groups with efforts to ensure some degree of comparability across groups in terms of school and grade level. The analyses also controlled for teachers' initial status on the outcome measures. However, teachers were not randomly assigned to conditions, so factors other than the LTG PD may account in part for the impacts that were found. The field test also provides initial evidence that teachers' engagement in the LTG Foundation Module can lead to improvements in related student knowledge. An important limitation of the field test was the lack of systematic investigation of any changes that may have occurred in participating teachers' classroom geometry instruction, so the link to student outcomes, while promising, remains relatively tenuous.

The empirical evidence supporting the intervention has thus far been based on data in settings where the materials were used within the research and development process. The finalized version of the Foundation Module has not been tested, nor has the complete package of the LTG PD materials (which includes four Extension Modules) been used with any group of teachers at this point in time. Given the intervention's demonstrated potential, a critical next step is to study

the delivery of the finalized version of the intervention by trained, external facilitators, and carefully examining the impact on teachers' knowledge, changes in their instructional practices, and related improvements in their students' knowledge.

UNDERSTANDING PROSPECTIVE TEACHERS' LEVELS OF GEOMETRIC THOUGHTS: INSIGHTS FROM A DISCURSIVE ANALYSIS

Sasha Wang
Boise State University
sashawang@boisestate.edu

The study investigates the characteristics of prospective teachers' geometric discourses at the van Hiele model of thinking (1959/1985), using Sfard's (2008) discursive framework. In this report, I align two prospective teachers' pre- and post- van Hiele geometry test (Usiskin, 1982) results with the analyses of their geometric discourses from clinical interviews, to illustrate changes in geometric discourse when a student's test results showed no change in van Hiele levels, and changes in geometric discourse when a student developed her thinking to the next van Hiele level. Revisiting the van Hiele model of thinking, complemented with a discursive lens, helped to understand learning as change in discourses, as prospective teacher develop thinking toward a higher van Hiele level.

Keywords: Geometry and Geometrical and Spatial Thinking, Learning Progressions, Teacher knowledge

The van Hiele model of thinking, known as "the van Hiele levels", was developed by the Dutch educators Pierre and Dina van Hiele (1959/1985). Many researchers have confirmed the usefulness of van Hiele levels when describing the development of students' geometry thinking. However the same researchers often find levels lacking in depth, and they would like a more detailed description of students' levels of thinking. Hoffer's (1981) "Sample Skills and Problems" (p.11) provided a framework that connects the levels of development with five basic skills (e.g., visual skills, verbal skills, drawing skills, etc) that are expected at each van Hiele level. Battista (2007) refined the model with five levels of geometric reasoings. Given my focus on prospective teachers' learning in geometry, I consider the possibility of elaborating the van Hiele model of thinking with a discursive lens in scrutinizing prospective teachers' thinking. I claim that when a student's geometric thinking develops to a higher level, simultaneously there is a development of the student's geometric discourse in discursive terms. If so, the question is, "What additional information does the analysis of geometric discourse provide about prospective teachers' levels of geometric thoughts?"

Theoretical Framework

The van Hiele model continues to be the best-known theoretical account of students' learning of geometric figures and their properties. The model suggests students must progress through a sequence of discrete, qualitatively different levels of geometry thinking. The first four levels in the model are as follows: Level 1, the Visualization level in which students recognize and learn the names of the figures, and figures are judged by their appearance as a whole; Level 2, the Descriptive level, when students begin to recognize figures by their properties or components; Level 3, the Theoretical level, where students begin to form definitions of figures based on their common properties, and understand some proofs; Level 4, the formal logic level, when students understand the meaning of deduction and conduct mathematical proofs using theorems.

My study departs from the van Hiele model, which accepts the basic idea of the levels of geometric thinking and of these main characteristics. In my rendition, thinking becomes a form

of communication, and levels of geometric thinking become levels of geometric discourse. This view of geometric thinking as geometric discourse entails that thinking is communicated through interactions.

Sfard (2008) has proposed that mathematical discourses differ one from another in at least four features: 1) *Word use* (mathematical vocabularies and their use), mathematical words that signify mathematical objects or process; 2) *Routines*, these are well-defined repetitive patterns characteristic of the given mathematical discourse; 3) *Visual mediator*s, these are symbolic artifacts related especially for particular communication; 4) *Endorsed narratives,* any text, spoken or written, which is framed as description of objects , of relations between processes with or by objects, and which is subject to endorsement or rejection, that is, to be labeled as true or false. These features interact with one another in a variety of ways. For example, endorsed narratives contain mathematical vocabularies and provide the context in which those words are used; mathematical routines are apparent in the use of visual mediators and produce narratives.

In what follows, the van Hiele behavioral descriptions at each van Hiele level are reviewed and analyzed with discursive terms (see Wang, 2011). For example, at Level 1, "a child recognizes a rectangle by its form, shape" (the van Hiele quotes), provides information about how a child identifies a figure, what it calls "a rectangle", based on its physical appearance. In discursive terms, the *vocabulary,* "rectangle", signifies a geometric shape has a name, and it is used as a label of the figure. The phrase, "recognizes…by its form, shape" suggests that the direct recognition triggers the decision making, and therefore the *routine* for this course of action is perceptual experience and it is self-evident (i.e., [it is] a rectangle [because I can see it] by its form, shape). The *narrative* is "what is said or described" about the object. The *visual mediators* in this situation could include a drawing or picture of a four-sided figure looking like a rectangle. As described, using the discursive lens not only allowed me to capture what students said, but also what they did when communicating their thinking. Viewing each van Hiele level thinking as its own geometric discourse, and with the help of the discursive lens, I expected to be able to arrive at a refined, "high resolution" picture of the process of geometric thinking.

Method

This report focuses on two participants. Sam and Lulu were prospective teachers, enrolled in a certain mid-west university teacher education program in the United States. They were enrolled in a measurement and geometry course as part of their program requirements. They participated in a pre- and a post-van Hiele Geometry Test (see Usiskin, 1982) as class assignments. One week after Sam and Lulu took the pre- and post-tests, they participated in 90-minutes pre-and post-interviews. The interview tasks are designed to elicit students geometric thinking and they are aligned with van Hiele geometric tests (see Wang, 2011). All the interviews are video recorded and transcribed for further discursive analysis.

I analyzed Sam and Lule's written responses from the van Hiele geometry test results using the test grading methods provided by the Chicago project team (Usiskin, 1982) to get initial information on their levels of geometric thinking. I also analyzed Sam and Lulu's interview transcripts in both what they said and what they did as course of actions during the interviews. In the following section, I share results about Sam and Lulu's test results and their interview analyses to learn more about the process of geometric thinking.

Results

Viewing the van Hiele model with discursive terms sheds light on what vocabularies participants used in describing geometric figures, and how these vocabularies were used in

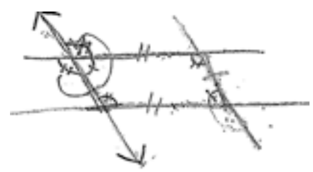
communicating mathematical thinking. The discursive lens helped to bring participants' actions to light, making it possible fro me to differentiate how they substantiated their narratives, either at a meta-level or at an object-level.

Continuity Within A Van Hiele Level: Sam's Case

Sam's van Hiele tests suggested that she was at Level 2 at the pre-test and stayed at Level 2, with no changes in van Hiele levels, but I found changes in her geometric discourses. The analyses of Sam's geometric discourses showed that her use of the word parallelogram changed. When she spoke the word "parallelogram" at the pre-interview, she meant any polygon having pairs of parallel sides, using a definition of parallelogram with only a necessary condition. For example, Sam was asked to draw a parallelogram and then a new parallelogram different from the previous one. Sam's course of action is as follows:

Interviewer: Why is this a parallelogram? [Pointing at the parallelogram]

Sam: I drew it so that this side would be parallel to this side [pointing at the two longer sides of the parallelogram], and this side would be parallel with this side [pointing at the two shorter sides of the parallelogram] Note: Sam drew a parallelogram first, and extended the sides of the parallelogram later.

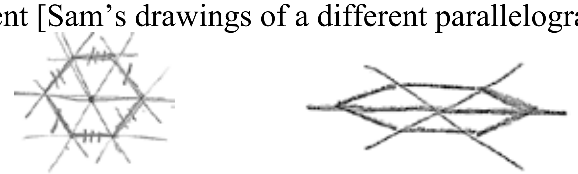


Interviewer: Why is this a parallelogram? [Pointing at the hexagon]

Sam: … because all the sides are parallel to another side.

Interviewer: Why is it a different parallelogram?

Sam: It's different because there are more sides and because the angles are different [Sam's drawings of a different parallelogram].

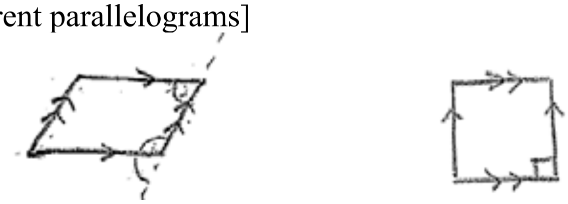


When communicating about parallelograms at the pre-interview, Sam considered two types: 1) "a parallelogram is a figure with all sides being part of parallel line segments (i.e., rhombi, parallelograms, hexagons, octagons, etc.); and 2) "it is a figure that has at least one pair of parallel sides, I think a trapezoid is a parallelogram". Sam did not consider squares and rectangles as parallelograms at the pre-interview.

At the post-interview, the same task was performed and Sam responded to the task with two drawings, a parallelogram and a square.

Interviewer: Why is this a parallelogram? [Pointing at the parallelogram].

Sam: … because it has four sides and each opposing side is parallel to one another. [Sam's drawings of two different parallelograms]

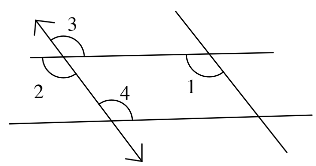


Interviewer: Why is this a parallelogram? [Pointing at the square]
Sam: It's a square, square is also a parallelogram, it has four equal sides and all angles are 90 degrees [Pointing at the square]. It's a different parallelogram from the one I drew because all the angles in this figure are equal.

It is notable that Sam's use of the word parallelogram evolved from pre-interview to post-interview, showing changes in her understanding of parallelograms, with regard to the added necessary conditions "four-sided" figure and "parallel sides". Moreover, Sam's grouping of parallelograms showed changes at the post-interview. She grouped parallelograms and rhombi together because "they all have two sets of parallel sides". She asserted, "rectangles are parallelograms with four right angles", as well as "squares are parallelograms with four right angels and four sides are equal." I argue that, at the post-interview, Sam had a good grasp of the concept of parallelograms in general, but her understanding of the hierarchy of parallelograms was missing, or not clearly demonstrated in the interviews.

There were also changes in Sam's substantiation routines. Substaintiation routines are repetitive patterns charaterising how Sam justifies or proves that naratives she provides are true or false. For example, at the pre-interview, Sam frequently used reflections, rotations and translations in her substantiations of narratives as concrete descriptions of her investigations.

Interviewer: How do you know ∠1 is equal to ∠4?

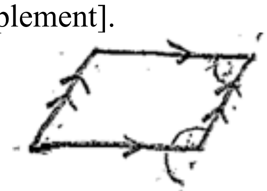


Sam: This angle [∠1] can just be slid over to this position and create ∠2, this line (the one with arrowheads) can be rotated so that ∠2 becomes ∠3. This angle [pointing at ∠3] at this intersection can just slide down and be in this angle's position [pointing at ∠4]. So two angles (∠1 and ∠4) are equal.

In this explanation, Sam used words such as "slide over", "create", "rotated" and "slide down" to indicate a sequence of imaginary movements performed to substantiate the narrative "two opposite angles [∠1 and ∠4] are equivalent". Sam's substantiation was intuitive and visual, and was focused on the descriptions of how lines and angles moved, rather than on the discussions about the results. Sam's routines operated at an object-level at the pre-interview.

In contrast, at the post-interview, Sam was able to use endorsed narratives (i.e., mathematical axioms and propositions) to verify her claims. The following brief substantiation was typical at the post-interview:

Interviewer: How do you know all angles in a parallelogram add up to 360 degrees?
Sam: Because angles on a straight line are going to add up to 180 degrees [Pointing at ∠2 and its complement].



Sam: This angle here is the same as this angle [pointing at ∠2 and its transversal exterior angle] because the parallel lines meet a third line at the angle. By the

> same reason, this angle added to this angle [pointing at ∠1 and ∠2's transversal exterior angle] equals 180 degrees. These two angles [∠1 and ∠2] added up to 180 degrees. For similar reasons, these two [opposite angles of ∠1 and ∠2] added up to 180 degrees. Together they [all four angles of the parallelogram] equal to 360 degrees.

Sam explained why two transversal angles are equivalent, not because you "can see it" as in the pre-interview, but as a result of "two parallel lines meet a third line at the same angle", and reached her conclusion that " they [all four angels of the parallelogram] equal to 360 degrees" by repeating a similar substantiation, "two angles add up to 180 degrees", for two adjacent angles in a parallelogram.

Note that the term "geometric object(s)" refers to all the mathematical objects involved in a particular geometric discourse. In my study, geometric objects discussed are quadrilaterals. The term "substantiation" refers to substantiations at an object-level and at a meta-level. The object-level substantiation emphasizes students' routines in describing the process of how quadrilaterals are investigated. For example, describing static lines, angles and polygons as movable entities under transformations (i.e., rotation, translation and reflection), is a way of substantiation at an object-level. With regard to definitions of different quadrilaterals, routines of substantiation depending on measurement routines to check the sides and angles of quadrilaterals, without thinking about how quadrilaterals are connected, are other examples of an object-level of substantiation. Object-level substantiation is a course of action where the student focuses on what she sees intuitively in explaining geometric objects (i.e., quadrilaterals) during the investigations. In contrast, a meta-level substantiation is a course of action where the student uses endorsed narratives to endorse new narratives. That is, students use mathematical definitions and axioms as results of investigations to construct mathematical proofs.

Two main changes in Sam's geometric discourse are change in word use and change in routines. Sam had developed competence in using definitions to identify and to group polygons with no hierarchy of classification, and had developed some informal deductive reasoning as her geometric thinking moved towards Level 3. Here, I am not trying to contradict the findings from Sam's van Hiele Geometry tests with her interview results, but rather to compile the results and to treat her thinking more explicitly and dynamically. The development of Sam's geoemtric discourse provides evidence of a student's geometric thinking developing continuously within Level 2 and in transition between Level 2 and Level 3, as she became more competent in using definitions to identify polygons, and her routines of substantiation began to operate at a meta-level in using definitions and axioms to construct mathematical proofs.

Continuity Within Two Consecutive Levels: Lulu's Case

Lulu was one of the two prospective teachers of the study who reached Level 4 based on the van Hiele geometry post-test. Lulu was at Level 3 in the pre-test and demonstrated a typical behaviour at this level. So one might ask, "what did Lulu's geometric discourse look like in moving from Level 3 to Level 4?" The detailed analyses of changes in Lulu's discourses are documented in my dissertation (see Wang, 2011). I summarize the changes briefly here. Lulu was at Level 3, coming in with the ability to use definitions to identify and group quadrilaterals, but my analyses of Lulu's geometric discourse show that she did not demonstrate that quadrilaterals were connected in a hierarchy of classifications. For example, in the pre-interview, Lulu's use of the word *parallelogram* referred to two groups: 1) rhombi and parallelograms, characterized by "opposite sides are equal and parallel" and 2) rectangles and squares,

characterized by "opposite sides are equal and parallel, and they all have right angles". Lulu did consider squares as rectangles, but she made no connections between rhombi and squares. At the pre-interview, Lulu performed an object-level of substantiations. For instance, when discussing the angles of a parallelogram, Lulu responded that the opposite angles of a parallelogram were equal. The following conversation took place when she was asked for verification:

Interviewer: How do you know the opposite angles are equal [in a parallelogram]?

Lulu: You mean… prove it to you, that in every case it would be that way?

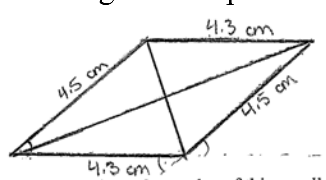
Interviewer: Yeah.

Lulu:I would just measure the angles for you, with a protractor. I've never done a proof before, in this case. I've done a lot of proofs, but not on something like that.

In this conversation, we learned that writing a geometry proof was new to Lulu, but she was aware of the differences between the generality of a mathematical proof and the particularity of checking the measurements of angles in a parallelogram when she asked, "prove it to you, that in every case it would be…?" In a similar scenario, Lulu measured the sides of parallelograms to verify her claim of, "the opposite sides in a parallelogram are equal".

Interviewer: How do you know opposite sides are equal?

Lulu: In this parallelogram? I can measure it. So, this is 4.5 centimetres, this is a little less than 4.5 centimetres [using a ruler to measure one pair of opposite sides]. Right, this is about 4.3. Yeah, it's about the same [measuring another pair of opposite sides].

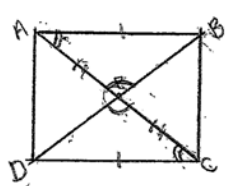


Interviewer: Is it true for every parallelogram?

Lulu: You mean to prove it? Well, I am not sure… but I know it's just a property of parallelogram.

The patterns of measuring sides and angles to verify equal measures were apparent in the pre-interview. In contrast, Lulu was able to demonstrate the hierarchy of classification among quadrilaterals using definitions at the post-interview, and she used propositions and axioms to construct mathematical proofs at that time. For example, Lulu provided a narrative, "diagonals bisect each other in a rectangle", and I asked for substantiation.

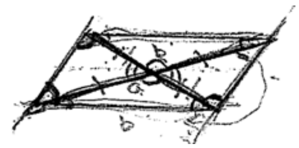
Interviewer: How do you know diagonals bisect each other in this case [pointing at Lulu's drawing, rectangle]?



Lulu: For the same reason as last time. Do you want me to explain again?

Interviewer: When you said, "for the same reason as last time", what do you refer it to?

Lulu: Just, all of it. When you draw diagonals in a rectangle, the diagonals create these congruent triangles. Based on the property, in all parallelograms, diagonals bisect each other. I know that the diagonals bisect each other in rectangles [pointing at the congruent triangles in the parallelogram].



The previous conversation signalled Lulu's ability in making relational transfer, from an endorsed narrative of "in all parallelograms diagonals bisect each other" to justify her claim about the diagonals in a rectangle. Given this opportunity, I asked for a written proof. Lulu's written proof is presented in Figure 1.

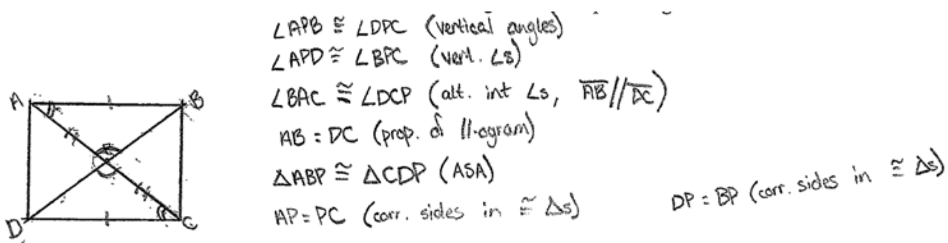


Figure 1: Lulu's Written Proof that Diagonals Bisect Each Other in a Rectangle at the Post-Interview

Lulu's geometric discourse presents a main characteristic of a Level 4 discourse that is absent in Level 3: abstraction of substantiations. Lulu showed Level 4 thinking in using definitions and axioms to construct proofs, and in using algebraic symbols to write a formal mathematical proof. However, at this level we also expect to observe behaviour where students are able to apply inductive reasoning in an unfamiliar situation. In Lulu's case, she was able to apply her knowledge of quadrilaterals to construct mathematical proofs in a familiar situation (e.g., to prove opposite angles or sides are congruent using congruent criterions), having carried out similar proofs in her geometry class for elementary teachers. When Lulu was asked to prove that two definitions of parallelogram were equivalent, she did not finish the proof because the task was new to her, and she did not know how to use the same axioms in a new situation. I argue that Lulu was at the beginning of Level 4 thinking, starting to gain the skills and languages needed for mathematical proof, but needing more practice to move forward to an advanced abstract level. Examining the changes from Lulu's Level 3 geometric discourse at the pre-interview to Level 4 at the post-interview, we observe movement from Level 3 thinking to Level 4 in developing a geometry discourse, in a continuous progression instead of jumps.

In addition, comparing Lulu's geometric discourse at Level 3 with Sam's at Level 2, we find similarities between Lulu's geometric discourse at the pre-interview and Sam's at the post-interview. Both shared familiarity with using definitions in identifying and grouping quadrilaterals, and were able to reason at an object-level. This observation also indicates the continuity of learning in transitioning between two consecutive levels, from Level 2 to Level 3.

Conclusions

The discursive framework provided opportunities to examine students' thinking in greater detail at each van Hiele level. It helped to analyse what students said (i.e. narratives and word use) about different parallelograms and their properties, and what they did (i.e., routines) when asked for substantiations. A careful analysis of students' mathematical word use sheds light on how words are used and whether the words are used correctly. Discursive routines do not determine students' actions, but only constrain what they can reasonably say or do in a given

situation, as negotiated conventions. However, discursive routines offer valuable information about what students do to make conjectures and justifications in a geometric discourse. I find it very useful to examine the details of students' routines of identifying, measuring, defining and justifying when working on a task about geometric figures and their properties, where the roles of definitions are demonstrated at the first three van Hiele levels. I also find it revealing to see the details of students' geometric reasoning across van Hiele levels through the development of geometric discourses.

Battista (2007) argues about the validity of the reasoning, which involves the accuracy and precision of students' identifications, conceptions, explanations, justifications, and points out that "there is a lack of distinction between *type of reasoning* and *qualitatively different levels in the development of reasoning*" (p.853) throughout van Hiele studies. For instance, a student used direct recognition as a type of reasoning that is strictly based on intuition, and used the same type of reasoning to refer to a period of development of geometric thinking when the student's thinking was dominated by direct recognition. One challenge regarding the van Hiele model is to sort out the levels related to type of reasoning and/or the levels of reasoning; and of course, "the devil is in the details" (p.854). Viewing geometric thinking as geometric discourse, Sfard's discursive framework takes a greater consideration of the details.

Acknowledgment

I am grateful to my two advisors during my graduate study, Dr. Glenda Lappan from Michigan State University and Dr. Anna Sfard from University of Haifa for their ongoing support and advice.

MATHEMATICAL PROOF TOOLS: SUPPORTING THE INTRODUCTION TO FORMAL PROOF

Michelle Cirillo
University of Delaware
mcirillo@udel.edu

In this study, conceptual tools that worked to support teachers and their students in the introduction to formal proof in geometry are introduced. The tools provided teachers with a means for scaffolding proof. Study teachers reported positive outcomes from using these tools with their secondary students. Additional studies that explore the use of the tools with instructors in varying contexts are warranted to determine how they can be used to improve the teaching and learning of proof in other classrooms, even potentially in content areas other than geometry.

Keywords: Reasoning and Proof, Geometry, Curriculum, Mathematical Knowledge for Teaching

Considering the teachers' role in navigating the proof terrain, Herbst (2002) conducted an analysis of what is involved when geometry teachers attempt to engage students in the production of a proof. He argued that alternative ways of engaging students in proving must be found if proving is to play, in the classroom, the same instrumental role for knowing mathematics that it plays in the discipline. Thinking about possible instructional alternatives for the reform-oriented classroom as an opportunity, Herbst (2002) stated: "The mandate to involve students in proving is likely to be met with the development of tools and norms that teachers can use to enable students to prove and to demonstrate that they are indeed proving" (p. 200). Calls for the development of teaching tools are important because symbolic tools can enable, mediate, and shape mathematical thinking (Sfard & McClain, 2002). Mathematical tools, which can be viewed as supports for learning, include physical materials, oral language, written notation, and any tools with which students can think about mathematics (Hiebert et al., 1997).

A primary goal of this paper is to introduce a set of conceptual tools that were developed and piloted in a research project whose aim was to explore alternative strategies for navigating the introduction to formal proof in high school geometry. The research question addressed in this paper is: What tools can be used to support teachers' work of introducing proof?

Theoretical Perspective

Despite recent efforts to increase the role of reasoning and proving in school mathematics, geometry remains a central content area for teaching this important mathematical process (Newton, 2010). However, the paucity of more formal reasoning and proof experiences throughout the school mathematics curriculum contributes to the difficulty of teaching and learning proof even in geometry (Clements, 2003). To add to this challenge, some secondary teachers claim that they do not have strategies for teaching proof and even expressed the belief that you cannot teach someone how to construct a proof (Cirillo, 2011). This belief may be an underlying reason that geometry is commonly thought of as the most difficult portion of school mathematics (Knuth, 2002). The well-known challenges that students have with proof (Senk, 1989) may also contribute to these beliefs.

Much of the work of Herbst and colleagues has focused on classroom interactions and proving in geometry at the secondary level. For example, Herbst et al. (2009) described instances

of student engagement with proof in various geometry courses in a high school. Through this work they unearthed a system of norms that appear to regulate the activity of "doing proofs" in geometry class. The authors contended that a collection of actions related to filling in the two-column form are regulated by norms that express how labor is divided between teacher and students and how time is organized as far as sequence and duration of events. As an example, the first 4 of 25 norms reported by Herbst et al. (2009) are listed below:

> Producing a proof, consists of (1) writing a sequence of steps (each of which consists of a "statement" and "reason"), where (2) the first statement is the assertion of one or more "given" properties of a geometric figure, (3) each other statement asserts a fact about a specific figure using a diagrammatic register and (4) the last step is the assertion of a property identified earlier as the "prove"….(pp. 254-255)

This model of the instructional situation of doing proofs in terms of a system of norms is helpful to those who wish to investigate what it might mean to create a different place for proof in geometry classrooms (Herbst et al., 2009). The documentation of classroom norms is relevant here because it provides a frame for examining the alternative practices supported by the tools used by the teachers in this study. This study builds on the work of Herbst and colleagues by examining possibilities outside of these normative practices.

Methods

To learn more about the challenges that teachers face when cultivating formal proof in their classrooms, a three-year study that made use of qualitative methods of inquiry, was designed. Baseline data, collected in Fall, 2010, included two non-consecutive weeks of classroom observations in one target classroom of six teachers. Beginning Spring, 2011, 20 professional development sessions were designed and implemented to assist the project teachers in: attending to the ways in which they introduced proof; reading the literature and considering alternative practices; and re-considering the discourse in their classrooms when they were teaching proof. In Fall, 2011 and 2012, additional data were collected to observe and understand changes made to the introduction and teaching of proof in geometry. Interviews designed to help the researcher better understand the teachers' evolving beliefs about teaching proof were also conducted.

Findings: The Development and Use of Mathematical Proof Tools

After analyzing the baseline data from Year 1 of the study, it was determined that several skills were implicitly and simultaneously being taught when teachers first introduced proof. Students needed to learn: (a) postulates, definitions, and theorems; (b) how to *use* definitions and theorems to draw conclusions (c) how to work with diagrams (e.g., what can and cannot be assumed); (d) a variety of sub-arguments and negotiated classroom norms for writing them up; and (e) how sub-arguments come together to construct the larger argument. It was through these observations in conjunction with the consideration of a claim that one of the teachers (Mike; all names are pseudonyms) made during his introduction to proof (i.e., that there is no shallow end, but only a deep end of proof) that the Mathematical Proof Tools (MPTs) were developed. Based on the shallow end proof pool metaphor suggested by Mike, I hypothesized that perhaps there was a set of skills and practices that students need in order to develop proofs that could be ramped up over time. The professional development sessions and subsequent observations gave me a way to test that hypothesis. In Spring, 2011, the group of teachers and the research team began meeting for professional development where the developing ideas for the MPTs became a

major focus of alternative teaching approaches. The tools began as sample alternative tasks inspired by Cirillo & Herbst (2011) and evolved into the conceptual tools presented in Table 1.

Table 1: Mathematical Proof Tools (MPTs)

Conceptual Tool	Description	Practices That Scaffold Proving
Understanding Mathematical Objects	This tool connects a mathematical object to a definition, notation, or a diagram.	1) Communicating a mathematical object by making use of spoken or written text
		2) Communicating or reading a mathematical object by making use of marked diagrams
		3) Communicating or reading a mathematical object by making use of symbolic notation
		4) Determining examples and non-examples of mathematical objects
Drawing Conclusions	This tool presents the idea of an open-ended task that leads to conclusions that can be drawn from given statements and/or a diagram.	1) Understanding what can and cannot be assumed from a diagram and recognizing that sometimes diagrams can be misleading
		2) Knowing when and how definitions can be used to draw a conclusion from a statement about a mathematical object
		3) Using combinations of postulates, definitions, and theorems to draw valid conclusions from some given information
Sub-arguments	This tool presents the idea that there are common short sequences of statements and reasons that are used frequently in proofs and that these pieces may appear relatively unchanged from one proof to the next.	1) Understanding what valid conclusions can be drawn from a given statement and how those make a sub-argument (i.e., recognizing and utilizing repeated reasoning)
		2) Recognizing a sub-argument as a branch of a larger proof and how it fits into the proof
		3) Understanding how to write particular sub-arguments using acceptable notation and language (often negotiated with the teacher)
Understanding Theorems	This tool highlights the nature of theorems, their structure, and how they are used.	1) Interpreting a theorem statement to determine the hypotheses and conclusion
		2) Marking a diagram that satisfies a hypothesis
		3) Rewriting a theorem written in words into symbols and vice versa
		4) Understanding that a theorem is not a theorem until it has been proved (using definitions, postulates, or previously proved theorems, lemmas, and propositions) and that one cannot use the conclusions of the theorem itself to prove the conclusions of that theorem (i.e., avoiding circular reasoning)
		6) Determining the theorem proved when presented with a proof
		7) Understanding the connection between logic and a theorem, for example, how to write the contrapositive of a conditional statement and the connection between laws of logic and the hypothesis and conclusion of a mathematical statement

Teachers' Reactions to the MPT Use

Seth reported the following after teaching with the tools in Years 2 and 3:

The students see the patterns and understand the relationships, which ultimately makes this a much better exercise in learning to reason. Breaking it into pieces has made it easier for the students to digest and understand the material and see how it fits together. The evidence is in a greater understanding, drawing better conclusions, and getting better grades on harder proofs! Some students even say, "That was fun!"

Nick reported similar results:

> I'm actually excited to teach proof now, which was not the case before the professional development. Proof is the centerpiece for the most interesting discussions we have in class, and it is no longer a stand-alone topic for me that we don't revisit after Chapter 2.

Nick noted that he keeps the MPTs summary (Table 1) on his desk at all times so that when he plans his lessons, he is always considering which tools he can address.

Discussion and Summary

The conceptual tools described in this paper were developed in response to some of the findings related to the challenges of teaching and learning proof in high school geometry. These tools were intended to scaffold the introduction to proof for the students. Although this study only presents findings of a small group of teachers' results in using the MPTs, these findings are promising because the teachers did more than just use the tools in a casual way. Rather, they saw enough potential in the tool use to develop a new curriculum around them, and they reported strong effects from their use. Additional studies that explore the use of these tools with other teachers in varying contexts are warranted to determine how these tools can be used by teachers to improve the teaching and learning of proof, even potentially in other content areas.

ONE HIGH SCHOOL STUDENT'S DEVELOPMENT OF MATHEMATICAL DISCOURSE ON TRANSLATION

Elçin Emre	Beste Güçler	Ziya Argün
Gazi University	University of Massacuhetts Dartmouth	Gazi University
elcinemre@gazi.edu.tr	bgucler@umassd.edu	ziya@gazi.edu.tr

The aim of this study is to explore one Turkish high school student's learning of the geometric concept of translation using a communicational approach. Our approach formulates learning as occurring through the changes in students' discourses as they interact with mathematical concepts. Our results confirm that the student's learning about translation was closely related to the changes in particular elements of his discourse. We conclude that the framework we used provides rich tools with which to examine stages of learning as well as the elements of discourse that play important roles in mathematical learning.

Keywords: Geometry, Learning Trajectories, High School Education

Introduction

Transformation is one of the significant concepts in learning of geometry that allows students to develop broad concepts like congruence and similarity (Jones, 2002). There are many studies that focus on students' learning on transformational geometry from cognitive perspectives (e.g., Clements, Battista, & Sarama, 2001; Hollebrands, 2003). However, few studies have explored the issue through a socio-cultural approach. This study explores one Turkish high school student's learning of the geometric concept of translation using a communicational approach to cognition, which considers learning as the process of change in students' discourse (Sfard, 2001). This study is part of a larger research that explores students' development of discourse on transformational geometry. For space reasons, we only consider the concept of translation here and we address the following questions: How does a (10^{th} grade) student's discourse on the concept of translation develop? More specifically, how do the elements in his discourse change as he continues to participate in the discourse on translations?

Theoretical Background

In this paper, we use Sfard's (2008) communicational approach as a theoretical framework. According to this lens, thinking is a special form of communication and the individual who is thinking is considered to be self-communicating. Sfard (2008) explains communication as a dialogical endeavor; it can be intra-personal or interpersonal. Learning is about changing the ways we think and how we communicate what we think (Sfard, 2001). Learning here is conceptualized as change in one's discourse and students' thinking can be examined through their discourses (Sfard, 2001). According to Sfard (2008), discourse is a "special type of communication made distinct by its repertoire of admissible actions and the way these actions are paired with re-actions" (p.297). If the content of a discourse is mathematical, Sfard (2008) describes it as a mathematical discourse.

There are four elements of mathematical discourse: word use, routines, visual mediators and narratives (Sfard, 2008). *Word use* is one of the distinctive characteristics of discourse, the vocabulary that learners use. There are four phases in the development of word use: first one is *passive use*, where the learner is "not able use a [mathematical] word in her own speech" (Sfard, 2008, p.181). The other is *routine-driven use*. In this phase, a mathematical word is uttered to

signify the learner's actions on the mathematical object. In *phrase-driven use*, "words become linked to constant phrases rather than with the whole routines" (Sfard, 2008, p.181). Last phase is *object-driven use*, where words signify mathematical objects. *Routines* are repetitive patterns in the actions of learners that are characteristic of the discourse. *Visual mediators* are visible objects that are operated through the communication process, like symbols, graphs, drawings, tables. *Narrative* is any sequence of any utterances indicating the relationships among mathematical objects.

The purpose of this study is to investigate one high school student's development of the concept of translation by using the four elements in his discourse.

Methodology

The study was conducted with one 10th grade student named Okan (a pseudonym) in a medium-sized, urban high school in Turkey. The data for this work was collected through three task-based interviews across six weeks to explore Okan's development of mathematical discourse particular to the geometric concept of translation. Okan was selected as a participant because he was observed in the classroom as an uninterested student but occasionally gave interesting answers to the teacher's questions. Although his grades were low in geometry, the informal interviews with the teacher suggested that his geometrical learning was enhanced throughout the discussions in the classroom. The researchers prepared three different task-based interviews about translations. Each interview lasted about 20 minutes and was video-taped. First interview was conducted before the teacher introduced the topic of translation in the class. Second interview was right after the translation class. The third one was conducted 25 days after the second interview.

Each interview consisted of four types of tasks on the concept of translation. Across the three interviews, each type of task was equivalent to those of the same type in terms of the nature of the translation problem presented and the skills the student needed to use when solving the problem. To ensure equivalence and the validity (Patton, 2001) of the tasks, five experts reviewed the tasks in terms of their parallelism and content. The interviews were conducted in Okan's native language and then translated from Turkish into English by the authors. Data were analyzed in terms of word use, visual mediators, routines and narratives (Sfard, 2008).

Results

We analyzed word use considering the context of the discourse in a qualitative way rather than a quantitative way. Throughout the interviews, passive word use about translation was not observed in Okan's discourse.

Interview I

During this interview, Okan's word use was mainly routine-driven. For example, when we asked him what it means to translate an object, he said that it "is the process of positioning the object from one location to another." In terms of visual mediators, Okan's focus was on the vectors and how he can split them into their corresponding x and y-components. However, his use of these mediators was not consistent. In fact, during the first interview, Okan had no consistent routine with which he translated mathematical objects. He used some strategies for the problems in a haphazard rather than repetitive way. Therefore we could not identify any routines in his discourse at this stage. Okan was also confused about which narrative to endorse regarding translation. Results indicate that, before the teacher introduced translation, Okan considered translation as the process of repositioning the location of an object but did not have robust

understanding of the concept.

Interview II

The second interview was conducted after the teacher introduced the topic of translation. In this interview Okan's word use was predominantly phrase-driven. For example, when we asked him what translation is, he said "translation is when the objects are moved towards particular directions within the coordinate system". There were also some object-driven utterances in his discourse. For example, he said that "Translation is a transformation that enables the placement of objects within the coordinate system".

There were four kinds of routines (three geometric and one algebraic) determined in Okan's second interview. Every time Okan translated a geometric shape and gave examples for translation, he used these two geometric routines (GR1 and GR2): GR1. Translating one vertice of a given geometric object along the components of the vectors visually and then using the property of translation (it preserves size and orientation) to draw the rest of the translated object. GR2. Translating each vertice of a given geometric object along the direction of the vector and carrying the vertices to its translated location and then connecting the vertices of the translated shape using the property of translation.

After Okan translated objects using GR1and GR2, the researchers asked Okan to find the coordinates of each translated vertice. Okan's responses to these questions elicited one geometric (GR3) and one algebraic (AR1) routine: GR3. Finding the coordinates of the vertices visually using the grids provided in the questions. AR1. After using GR3, Okan regularly wanted to double-check his answer algebraically by adding the coordinates of each vertice of the original shape with the corresponding coordinates of the vector.

Vectors were the primary visual mediators in Okan's discourse during the second interview. He considered vectors as objects that move the geometric shapes as indicated by one of his geometric routines (GR2). He also used vectors algebraically, treating them as ordered pairs as indicated by his algebraic routine (AR1). One of the endorsed narratives that Okan used in his words, routines and visual mediators was: "Translation is the placement of objects in the coordinate system".

When we compare Okan's discourse in this interview with his first interview, we see the following changes in the elements of his discourse: (a) His mainly routine-driven word use changed to being mainly phrase-driven, and (b) his haphazard solution strategies changed to consistent routines in his discourse. He became close to objectifying translation as a form of transformation that preserves the size and orientation of any given geometric object.

Interview III

The third interview was conducted 25 days after the second interview. In this interview, Okan's word use was mainly object-driven. When talking about translation, Okan frequently referred to the translated geometric objects as the end states of the translation process. There were also some phrase-driven utterances in his discourse. For example, while Okan was translating a geometric object, he said "When an object is translated, area, circumference, and the distance between the points [of the original shape] do not change".

In this interview, we identified one geometric routine in Okan's discourse. He used this routine in three of the tasks on which he worked. Throughout the tasks, his approach was generally based on geometric rather than algebraic routines. His geometric routine was GR1. In terms of visual mediators, Okan mainly operated with vectors geometrically rather than algebraically as indicated by his routine GR1. One of the most frequently endorsed narratives in Okan's discourse was: "If the object is translated...the distances between the points [vertices of

the original geometric object] do not change."

When we compare Okan's discourse in this interview with his second interview, we explored the following changes in the elements of his discourse: (a) His mainly phrase-driven word use changed to being mainly object-driven, (b) his four different types of routines (GR1, GR2, GR3 and AR1) were reduced and stabilized to one geometric routine (GR1), and (c) his phrase and object-driven utterances consistently treated translation as an object long after Okan's second interview. Accordingly, his endorsed narratives started resembling actual mathematical facts rather than idiosyncratic utterances he endorsed at the very beginning of his learning process.

Conclusion and Discussion

In this study, we explored Okan's learning of the geometric concept of translation, which was conceptualized as the change in his discourse (Sfard, 2008). Note that this framework does not only focus on students' use of language but also takes into account other elements in their discourse such as their actions and visual mediators. Our analysis of Okan's discourse revealed that these elements of discourse are in close relationship with each other as he shifted his routine-based discourse to an object-based one in the context of translations. The learning trajectory Okan went through in the course of the interviews resulted in changes in each element of discourse, indicating that students need to command all the elements of mathematical discourse in order to enhance their thinking (Güçler, 2013).

One critical aspect of mathematical learning is to change the talk about processes of mathematics to the objects of mathematics (Sfard, 2008). Okan's discourse reflected such development as his routine-driven word use gave way to phrase- and object-driven word use. For the concept of translation, this means a shift from considering translation as actions formed on geometrical objects to considering translation as a distinct mathematical object that belongs to a class of other mathematical concepts (i.e., transformations). A detailed analysis of student discourse helps identify the characteristics of students' trajectories and discourse regarding these important conceptual shifts in transformational geometry.

PRESERVICE TEACHERS' MATHEMATICAL KNOWLEDGE OF VOLUME MEASUREMENT

Eun Mi Kim
Michigan State University
kimeun23@msu.edu

To theorize about what preservice teacher "know" about volume measurement, this study explored the extent to which four preservice teachers demonstrated their mathematical knowledge through four tasks in an interview. I characterized the preservice teachers' knowledge of the major concepts and processes of volume measurement in three types of knowledge: conceptual, procedural, and contextual. Video and audio data was collected, and it was analyzed based on the coding scheme inductively developed for this research. According to the different measurement contexts, the participants showed different conceptions of volume as a number, capacity, enclosed volume, and weight; their conceptions of volume formulas were represented as a composition of cubic units. Some participants showed incomplete procedural knowledge in using volume units and had misconceptions connected with measurement contexts.

Keywords: Measurement, Teacher Knowledge, Teacher Education-Preservice

Teaching school mathematics requires subject matter knowledge in mathematics, and the knowledge should be based on explicit understandings (Ball, 1991). Teachers' knowledge is important not only for their teaching but also for their students' learning (Baturo & Nason, 1996; Fennema & Franke, 1992). We still have, however, little sense of what exactly it is that preservice teachers know, and how that knowledge is acquired and used. A possible entry point to study preservice teachers' mathematical knowledge is to work from what they "do" know—the mathematical knowledge (and skills) they use and the contexts in which these are understood—so that teacher education programs can provide appropriate support for them to develop a stronger mathematical knowledge.

The purpose of this qualitative study was to explore the mathematical knowledge of volume measurement of preservice teachers who will be certified to teach preK-8 grades. This study is a first step toward understanding how preservice teachers make sense of the concepts of volume in measurement and of volume formulas, an important topic in the elementary mathematics curriculum of spatial measurement (length, area, and volume). This need to study preservice teachers' understandings of volume measurement is also guided by the assumption that "an individual's knowledge of a concept may depend on the context in which the knowledge is elicited" (McNeil & Alibali, 2005, p. 286). The research questions guiding this study were (a) "How do preservice teachers explain the concepts of volume in different measurement contexts?" and (b) "How do preservice teachers understand volume formulas?"

Theoretical Framework

The theoretical framework is presented in three main sections that review the research related to: (a) conceptualizing volume concept with its measurement, (b) spatial reasoning behind volume formula, and (c) characterizing volume measurement knowledge.

Conceptualizing Volume Concept with Its Measurement

Piaget, Inhelder, & Szeminska (1956) found that children could hold three different meanings of the volume concept in measurement: (a) an interior volume (e.g., the number of cubic units that compose an object, or the amount of matter which is contained within the boundary surfaces), (b) a

volume as an occupied space (e.g., the amount of space occupied by an object as a whole in the relation to other objects around it), and (c) a complementary volume (e.g., the volume of the water displaced when an object is submerged). Other studies have revealed other meanings: volume as capacity (e.g., the volume of matter that fills a container as capacity), volume as enclosed volume (e.g., the free space enclosed in a closed surface), volume as a number (e.g., a number obtained from numerical information and by the volume formula), volume as a mental object or quality associated with a body's characteristic of having three dimensions (Sáiz, 2003), and volume as weight (Potari & Spiliotopoulou, 1996). A question is raised, in the end: what makes individuals to develop these different conceptual understandings of volume?

Reasoning Behind Volume Formula

Researchers have reported problems in K-12 students' understanding of measurement related to their memorization of formulas (Barturo & Nason, 1996; Clements & Stephan, 2004). In calculating volume by mathematical multiplication, students need to reason about the meaning of triple multiplication of lengths in three dimensions as logical multiplication of the relations between lengths or areas and volumes, involving relations between units of different powers (Piaget et al., 1956); and they also need to conceptualize the spatial structuring process that underlies numerical procedures (e.g., layer structuring, Battista 2003).

Characterizing Volume Measurement Knowledge: Three Knowledge Types

As a conceptual framework for this study, I characterized measurement knowledge in the sense of conceptual, procedural (drawing on Hiebert & Lefevre, 1986; Baturo & Nason, 1996; Lee and Smith, 2011), and contextual (drawing on McNeil & Alibali, 2005). Conceptual knowledge for volume measurement includes the idea that the volume of an object can be thought of as filling an object with the volume unit of measure, and that the term 'volume' can refer to the number of the volume units contained within an object. Procedural knowledge includes measurement processes such as reading markings on a ruler, counting a number of cubes, structuring an array of cubes, measuring the volume of water displaced when an object is submerged, and calculating volume by using volume formulas in cubic units. Contextual knowledge is the recognition of the need to select a unit (or scale), a tool, or notation that is appropriate to measure different attributes/substances, and to use different measurement strategies that are suitable in different measurement contexts (e.g., an empty shoe box as cubic inch/cm, a juice box as fluid ounce/liter, a plastic container filled with rice as ounce, gallons for gasoline or liters for bottled water). To explore how the understandings of volume measurement are acquired in preservice teachers' minds as mathematical knowledge, we need to hear from them concerning the meaning of volume in the measurement context and the process of using volume formulas to determine volume measurement.

Method

The preservice teachers' knowledge of volume measurement was observed as they answered interview questions and performed four tasks in an interview. Four preservice elementary teachers (Amy, Jane, Kate, and Sue, all pseudonyms) volunteered to participate in this study; all they were students in a mathematics course (mainly focusing on geometry and measurement) required for their elementary (K-8) teacher preparation. Individual interviews were conducted before volume measurement was taught in class. The interview instrument was designed as four volume measurement tasks; and three boxes—all rectangular prisms (given in the elementary textbook as a typical physical/concrete model of the volume formula, $L\times W\times H$)—were presented in the interview tasks: an empty shoebox, a plastic food container filled with rice, and a one-liter juice box. In this study design, the different substances of the three rectangular prisms (i.e., the content of each box) were taken to represent the different measurement contexts. The interviews were audio- and video-recorded, and written work during the interviews was collected. The collected data was analyzed for types of conceptual, procedural, and contextual knowledge.

Results

Conceptual Knowledge of Volume Measurement with Contextual Knowledge

In the first interview task, participants were presented with three boxes—an empty shoebox, a plastic food container filled with rice, and a one-liter juice box—and for each asked how they would think about the volume of the box. Participants described volume as the formula of $L \times W \times H$, the space claimed by the substance in a box, the amount of the substance itself in it, and the free space enclosed in a container; thus, their conceptions about the volume concept could be inferred as (a) a number obtained by the formula (Sáiz, 2003), (b) an interior volume in terms of capacity (Sáiz, 2003), (c) weight (Potari & Spiliotopoulou, 1996), and (d) enclosed volume (Sáiz, 2003), respectively. For example, Sue explained the volumes of the three boxes, as "I think of volume as the space it takes up inside of it" (assigned as enclosed volume); "The amount of space all the rice takes up" (assigned as capacity); and "What's inside of it is taken up by the liquid" (also assigned as capacity), respectively. Based on the participants' different volume descriptions by contextual variability (the substance/content of each box), it is possible to infer the context-dependency of participants' conceptions of volume concept.

In response to the question about what the number obtained by multiplying three numbers in the volume formulas means (Task 3), the responses of all of the participants referred to their original conceptions about the volume of the shoebox. To the question of how many cubes were needed to fill the shoe box (Task 4), Amy, Jane, and Kate answered that the total number of cubes equals the number obtained from the formula; and Sue attempted to visualize a layer structure of cubes first and then came up with her estimate. To check/justify their numbers, instead of filling up the shoebox with inch cubes, Amy and Jane located cubes along the lengths in three dimensions; Kate and Sue constructed layers of cubes. Participants' strategies of checking/justifying their estimates reflect their internalized image of volume formulas and mental models of volume measurement (Battista, 2003).

Procedural Knowledge of Volume Measurement with Contextual Knowledge

When asked to explain how they could know the volumes of three boxes (Task 2), participants' strategies for measuring the volume of each box fell into four main categories: (a) using formula, (b) counting the number of counting standard or nonstandard volume units in the container, (c) weighing the container, and (d) measuring the amount of the space (taken by the substance) within the box. The characteristics of participants' strategies reflected their conceptions of volume observed in Task 1, a number, capacity, weight, and enclosed volume, respectively. The assumption of the relation between their conceptions of volume and measurement context was confirmed by participants' different strategies to figure out the volumes of the three boxes.

For Task 3, actually measuring the volume of the shoebox with a ruler or tape measure, all of the participants used the volume formula (i.e., measuring the lengths in inches by using a ruler, and then calculating its volume by using a formula). Thus indicating that they acquired the procedural knowledge of how to use volume formula in measuring the volume of a rectangular prism. As a type of procedural knowledge, however, their understanding of volume measurement units and notation were incomplete. In calculating the volume of the shoebox in cubic inches, participants showed some common misconceptions about the measurement unit, such as incorrectly using a squared unit, which is for area, not for volume, or incorrectly using a decimal for fractional inch measurements.

Conclusion and Discussion

According to the different measurement contexts, the participating preservice teachers in this study presented different conceptions of volume; the context of volume measurement also affected their ideas of the appropriate measuring strategy of the volume of a rectangular prism. The different measurement contexts demonstrated the participants' incomplete and weak knowledge of volume measurement with some misconceptions. For instance, to figure out the volume of the juice box, both

Amy and Kate, who already measured the volume of the shoebox correctly, weighed the full boxes and wrote down their measures in kilograms (e.g., 1.09 kg). It is possible to infer that they were seeing volume as weight, or not distinguishing between volume and weight, in the context of measuring the volume of the juice box. This observation is consistent with McNeil and Alibali's (2005) comments: "[A]n individual may appear to have knowledge of a particular concept in one context but not in another" (p. 304).

Significance of the Study

This research study reveals pre-service teachers' incomplete knowledge of volume measurement, with its context-dependent nature (McNeil & Alibali, 2005). The concept of volume measurement, with respect to the construction of spatial structure and its quantification by means of volume formulas, is a concept that students in teacher education program must have a chance to understand in a variety of circumstance. This would better equip preservice teachers with the capacity to choose appropriate, flexible measurement strategies in different contexts and thus to have a more complete, solid understanding of volume measurement. The context-dependent nature of volume measurement knowledge presents the issue for further investigation and discussion within the mathematics education community, especially a formative effect of variations-across-contexts on mathematical knowledge change.

"ALL LINES ARE STRAIGHT": THREE GRADUATE STUDENTS' DIFFICULTIES CONCEPTUALIZING SPHERICAL GEOMETRY CONCEPTS

Muhammet Arican
The University of Georgia
marican@uga.edu

Keywords: Geometry and Geometrical and Spatial Thinking, Mathematical Knowledge for Teaching, Teacher Education-Preservice

My interest in Spherical geometry emerged after my first long distance flight experience from Istanbul to Philadelphia. While checking the flying route on the monitor, I observed that the plane was following a curved route, which was headed towards a little North. I wondered the reason of following a curved route and I found it interesting because in my view the route between Istanbul and Philadelphia must be straight since I believed shortest distance between two points can be reached by following a straight line. Therefore, this interest directed me to register two sequential geometry courses that are designed for secondary school mathematics teacher candidates at the University of Georgia. In these courses, I understood that the shortest distance between two points on a surface of a spherical object can be reached by following "great circles". I also observed that my classmates were also having similar difficulties to comprehend spherical geometry concepts. So I decided to do this pilot study for future research to understand graduate students' difficulties and their understanding of spherical geometry concepts.

Spherical (elliptic) geometry is one of the two types of non-Euclidean geometry that focuses on the geometric concepts of sphere or spherical surfaces. According to De Villiers (1996), non-Euclidean geometries were developed by Lobachevsky-Bolyai and Riemann in the nineteenth century. Three mathematics education graduate students were volunteered to investigate the following research questions:

1. How do graduate students understand the *straight* line concept on a spherical plane?
2. How do they calculate the distance between two points given on a spherical object?
3. How do they form a triangle and a rhombus on a spherical object and explore the angle sum of the spherical triangle?

Total five hours of semi-structured interviews were conducted to gather data. The interviews were conducted as teaching experiment type in nature, which means there was a teaching goal of the interviews. I accomplished this teaching goal by probing participants' responses.

This initial study yielded that none of the participants was able to correctly define a spherical line. Two of the participants correctly identified the formula for calculating the distance between two points on a spherical object but because of their misassumption of a spherical line their understanding was incomplete. For the last research question, it was observed that only one participant was able to give a reasonable answer for the angle sum of the spherical triangle. In addition, confusion and experiencing difficulty were observed while participants attempted to solve the given interview tasks. The results of this study suggest that further research is needed on this topic. Also, my personal suggestion is that educators should pay more attention to spherical geometry in high school and in college since in my view learning spherical geometry may help students to expand their geometric understanding and understand the Earth where we live on it in a better way.

EXPLORING STUDENT THINKING THROUGH ALTERNATIVE GEOMETRY PROOF TASKS

Michelle Cirillo
University of Delaware
mcirillo@udel.edu

Jamie Sutherland
University of Delaware
sutherla@math.udel.edu

Keywords: Geometry, Reasoning and Proof, Curriculum, High School Education

Textbooks or other curriculum materials are the main source of mathematical tasks used in classrooms (Stein, Remillard, & Smith, 2007). By extension, curriculum and task selection impact students' opportunities to learn reasoning and proof in geometry, the context of this study. Poor geometry achievement found at the secondary level, particularly in the area of proof, is well documented, and the curriculum has been noted as a primary factor (Clements, 2003).

To address this issue, some researchers have begun to develop alternative tasks and strategies for teaching proof in geometry (see, e.g., Cirillo & Herbst, 2011). The purpose of this study was to explore the following research question: How do students take up these alternative proof tasks towards the end of a high school geometry course? These tasks are considered alternative in the sense that they are not the types of problems that tend to be found in geometry textbooks. More specifically, in the work of proving a proposition in geometry, students are typically provided with the "Given" hypothesis and asked to write a proof of a particular "Prove" statement. Most of the time, they are also provided with the diagram to work the proof (Cirillo & Herbst, 2011).

An example of an *alternative* task used in this study was: "Suppose you conjectured that the diagonals of a rectangle are congruent and your teacher started you off with the diagram on the right [rectangle provided]. Write the 'Given' and 'Prove' statements that you would need to use to prove your conjecture." In May 2011 we sat down with five groups of students (n = 2-4 students per group) enrolled in a high school geometry course to work on a set of tasks. The students were asked to work through the tasks together as we video-recorded them working. Results indicated that students struggled to complete these tasks, and they noted that they were different from those tasks they typically encountered in their textbooks.

EXPLORING THE RELATIONSHIPS BETWEEN STUDENT MOON OBSERVATIONS AND SPATIAL-SCIENTIFIC REASONING

Merryn Cole	Jennifer Wilhelm	Christa Jackson	Hongwei Yang
University of Kentucky	University of Kentucky	University of Kentucky	University of Kentucky
merryn.cole@uky.edu	jennifer.wilhelm@uky.edu	christa.jackson@uky.edu	patrick.yang@uky.edu

Relationships between student moon observation journaling and sixth-grade students' spatial-scientific reasoning after implementation of an Earth/Space unit were examined. Teachers followed the NASA-based REAL (Realistic Explorations in Astronomical Learning) curriculum. Understanding many aspects of astronomy relies on an individual's ability to use the positions and motions of celestial objects to describe observed phenomena and to make predictions based on these observations (Plummer, Wasko, & Slagle, 2011). These astronomical explanations also require spatial ability, which is linked to performance in both mathematics and science (Black, 2005; Lord & Rupert, 1995). As such, the performance on a test of students' mental models of lunar phases should also correlate to their performance in mathematics. The Lunar Phases Concept Inventory (LPCI) was developed to assess students' mental models of lunar phases (Lindell & Olsen, 2002). These mental models are an important part of making sense of the world around us. Student moon observation journals foster a purposeful link between what students can observe about the world around them and the spatial relationships inherent in these observations. The act of keeping a moon journal is an interdisciplinary experience; it includes science observations as well as skills used in many other professions.

An extensive search was conducted in both the multilevel model (HLM) space and the single level model space. The final model identified for this data set is a single level linear model. The model shows that students performing better on moon observation journals, both in terms of overall score and number of entries, score higher on LPCI post-tests. For every 1 point increase in the overall moon journal score, participants are expected to score 0.18 points or nearly one percentage point higher on the LPCI post-test when holding constant the effects of the other two predictors, LPCI pre-test score and number of moon journal entries. An examination of the quality of moon journal entries demonstrates that students who put more effort into their moon journals appeared to notice more patterns in the appearance and location of the moon in the sky. These patterns additionally relate to their development of spatial skills as they are describing the apparently changing location of celestial objects in relation to their single position on Earth. This study is unique in the purposeful link created between student moon observations and spatial skills. The use of moon journals distinguishes this study further by fostering scientific observation along with skills from across STEM fields and other disciplines. Future work will continue to show a strong link between these improved spatial skills and performance in mathematics and science.

A HISTORICAL PERSPECTIVE ON GEOMETRY TEXTBOOKS' TREATMENT OF CONGRUENCE

Elizabeth Fleming
University of Maryland
fleming1@umd.edu

How do we approach thinking about modern high school geometry textbooks? What are useful perspectives for understanding these presentations of geometric knowledge? A historical perspective can help situate our understanding of current geometry textbooks (Donoghue, 2003). In particular this study explores changes in the idea of congruence in geometry textbooks over time. The more formal treatment of congruence as a mathematical idea has changed, perhaps even evolved, over the history of the discipline (Steiner, 1971; Berlinski, 2013). This study identifies and describes four of these disciplinary perspectives, based on the work of Euclid (Heath translation, 1956), David Hilbert (1899/1938), Felix Klein (1872), and George David Birkhoff (1932), respectively. A coding framework was developed based on these four perspectives to analyze the treatment of congruence in geometry textbooks from the late 19th century into the early 21st century. The textbooks selected are considered representative of the textbooks of that time period and/or are considered to have been in popular use within that time period (Donoghue, 2003). The results of applying this framework suggest four categories of congruence treatment in the textbooks over time, shifting from a treatment almost identical to Euclid to a measurement-based approach, rooted in Birkhoff's ruler and protractor postulates.

This historical framework brings to light a tendency in the modern textbooks examined toward incoherent treatments of congruence, which take up pieces from all four mathematical perspectives rather than aligning with any one. The Common Core State Standards for Mathematics (CCSS-M) root the idea of congruence in rigid transformations, aligning with the Klein perspective (National Governors Association Center for Best Practices and the Council of Chief State School Officers, 2010). In the modern textbooks analyzed, transformations were discussed only in a final chapter; transformations were not fundamental to these textbooks' presentations of congruence and similarity. Given that there were isolated textbooks that adopted a transformations-based approach, and that the modern textbooks analyzed do not, this study raises questions about the potential ramifications and challenges of the CCSS-M treatment of congruence for current and future high school geometry textbooks, curricula, and teaching.

PROVIDING RESEARCH-BASED GUIDANCE ON GEOMETRY AND MEASURES FOR TEACHERS IN MIDDLE AND HIGH SCHOOLS

Keith Jones
University of Southampton, UK
d.k.jones@soton.ac.uk

Keywords: Geometry and Geometrical and Spatial Thinking, Measurement, Curriculum

A recent report has suggested that if education is going to embrace evidence-based practice "in a serious way" then the first thing that is needed is better systems "for disseminating the findings of research to teachers on the ground" (Goldacre, 2013, p.16). With this in mind, this poster presents selected elements from a research project that has produced a research-informed resource that brings together, in focused sections, knowledge about mathematics and its teaching and learning in a way that is designed to be useful to teachers working in middle and high schools. The resource consists of a book (Watson, Jones, & Pratt, 2013) and a linked website; see: http://www.nuffieldfoundation.org/key-ideas-teaching-mathematics

The task of producing such a resource was approached through synthesizing a comprehensive range of relevant research about conceptual growth, through education, in key areas of the mathematics curriculum. Aimed at teachers, teacher educators, textbook writers, and curriculum policy makers for mathematics education at the middle and high school level, the resource is structured around seven key mathematical domains: relations between quantities and algebraic expressions; ratio and proportional reasoning; connecting measurement and decimals; spatial and geometrical reasoning; reasoning about data; reasoning about uncertainty; and functional relations between variables. Across these domains, the following are argued to be key powerful mathematical ideas: variable; proportionality; similarity; symmetry; linearity; measure; accuracy; dimensionality; representations; prediction; discrete/ continuous number; transformation; proof.

In geometry education, the research evidence synthesized indicates that teaching needs to attend to two closely-entwined aspects of geometry: the spatial aspects and the aspects that relate to reasoning with geometrical theory. These twin aspects of geometry, it is argued, are not separate, but interlocked. Six themes are identified: spatial relations, 3D geometry, symmetry and transformations, similarity and congruence, geometric diagrams, and geometric proof

In teaching topics in measurement, the synthesis of evidence indicates that the principles of measurement are not straightforward for many learners and may require more attention in school than is sometimes given. If the mathematics of measurement is neglected in teaching, this can store up problems for students when they progress to more advanced topics including graphs of functions, loci and vectors. Six themes are identified: measurement scales, compound measures, geometric measures, measurement and proof, angle measures and estimating measures.

ELICITING STUDENTS' CONCEPTIONS OF AREA THROUGH MODELING ACTIVITIES

Keywords: Modeling, Measurement, Instructional Activities and Practices

The use of Model-Eliciting Activities (MEAs) as an instructional tool in teaching mathematics to both preservice mathematics teachers and K-12 students in general holds great promise. By embedding rich mathematics content into open-ended and realistically complex problems, MEAs provide opportunities for teachers to examine students' thinking while at the same time creating engaging activities for students. According to a models and modeling perspective (Lesh & Doerr, 2003), students' conceptions, or mental models, develop and evolve as these models come in contact with or are evaluated against instructional activities. Model Eliciting Activities are designed specifically to challenge students conceptual models, thereby encouraging testing and revision of those models while at the same time allowing teachers a window through which to view students' conceptions. This study specifically examines the types of thinking revealed by students of widely different levels through one such activity.

In this study we compared middle school and undergraduate students' thinking around the concept of area in the context of the *Pelican* Colony MEA. This activity challenged students to develop a procedure for counting the number of pelican nests in different breeding grounds. Students were given aerial photos and maps of the colony to do so. In working on the challenge, they must determine a method for finding the area of an irregular shape. Students in an undergraduate course on algebra and modeling at a large midwestern university as well as 6th grade students in a suburban middle school participated in the MEA. Audio and video recordings of students' conversations while working the problem, as well as artifacts of students' work were analyzed for evidence of conceptions and misconceptions about area measurement using a comparative case study design.

Despite the wide difference in age and experience between the groups of students, several themes emerged across both group that parallel those outlined by Lehrer, Jaslow and Curtis (2003) and Clements and Sarama (2009). Students in both groups showed evidence of confusion of perimeter and area. Students who eventually developed a method based on covering the area with known units did so at varying degrees of sophistication; some repeatedly traced unit squares while others created arrays. Students also approached the counting of those arrays in both additive and multiplicative ways. These results demonstrate both the pervasive nature of certain conceptions even into college as well as the power of MEAs in eliciting students' mental models.

SIXTH GRADER'S FRACTION SENSE ON NUMBER LINE TASKS: ARE WE READY FOR THE COMMON CORE?

Kate J. Riley
California Polytechnic State University
kriley@calpoly.edu

Keywords: Rational Numbers, Standards, Measurement

The Common Core State Standards (CCSS) for mathematics featured the number line as a central representational tool in helping students understand that fractions are numbers that expand the number system beyond whole numbers (2010). The number line is featured prominently in second through eighth grade as a means for developing number sense.

Prior research by Bright, Behr, Post, and Wachsmuth (1988), Shaughnessy (2011), and Diezmann and Lowrie (2006) noted students' difficulties with number line tasks that included incorrectly identifying the unit and difficulty with tasks where the number line was partitioned into unequal parts. In light of the implementation of the CCSS, the goal of this research study was to replicate prior studies and to get a snapshot of students' ability to understand the partitioning of a unit by identify missing fractions on a number line and also their understanding of ordering of fractions on the number line. This study examined 71 sixth graders over a period of four weeks. Students were given two worksheets. The first worksheet included tasks in which a number line was partitioned into equal lengths such as thirds or fourths and students were given two whole numbers on the line. Students were asked to identify a missing fraction. For the second worksheet students were asked to plot the fractions 4/5 and 5/4 on a number line and then determine which fraction was closer to "1".

The results show that students had a difficult time finding the missing fraction on a number line especially when zero was not one of the whole numbers given. Only 34% and 35% correctly identified fractions of these types where the partitions were thirds and fourths respectively. It is concerning that only 18% of the 71 sixth graders could correctly answer and explain which fraction, 4/5 or 5/4, was closer to 1 given that the Illustrative Mathematics (2011) team listed this as a 3rd grade assessment item. These results suggest students have gaps in their understanding of fractional number sense especially in the area of ordering fractions on a number line. Given the importance of the number line within the CCSS, the implications of this study suggest that more research is needed that delves deeper into students' understanding of these tasks.

MIDDLE SCHOOL STUDENTS' MATHEMATICAL COMPREHENSION OF LATITUDE AND LONGITUDE

Christopher Russey	Jennifer Wilhelm	Christa Jackson
University of Kentucky	University of Kentucky	University of Kentucky
christopher.russey@uky.edu	jennifer.wilhelm@uky.edu	christa.jackson@uky.edu

Lines of latitude and longitude are part of a geographic coordinate system that is used to determine positions on the globe. These lines are measured in degrees because they correspond directly with the measure of an angle at the center of the earth. Also, instead of designating these measurements as positive and negative, the direction of the angle measure is indicated by the labels N, S, E and W. A full comprehension of global coordinate systems requires some mathematical understanding (spatial, geometric, etc.). The jump from simple grid work to longitude and latitude increases in complexity, as elementary students and adults struggle with the spatial reasoning needed to understand maps and direction (Muir, 1985). Students have an implicit cognitive coordinate system that they associate with physical objects that can become unrecognizable if viewed from a foreign orientation (Just & Carpenter, 1985). A student can become confused about notions of east and west in as it relates to an arbitrary measurement from a position, such as the prime meridian. And if they are to truly understand the motivation behind using this coordinate system to model the earth, students will have to have a fundamental understanding of angles. Students don't always recognize all aspects of angle measure, as a joining of two rays, as a wedged (or space between the rays) or as a turn from one ray to another (Browning et al., 2007). Students tend to struggle in defining what an angle is and what it measures (Keiser, 2004). There is little research available that looks into students' understanding of geographic coordinates in relationship to the mathematical concepts that it's based upon.

Middle school students, in an afterschool program, are participants in an interdisciplinary STEM curriculum that studies lunar and astronomical phenomena (Author). For an hour and a half each week, we studied students that were given inquiry and project-based lessons that that develop their mathematical and scientific reasoning and understanding. One lesson, in particular, has students investigate how to pinpoint exact locations on a globe, discover the relationship between angle measure and lines of latitude and longitude, and use this relationship to inform judgments about the relationship between the global coordinates and the position of the sun in the sky. The responses to questions and drawings were collected from the students who worked on the lesson. Our research of this data will seek to determine what mathematical understanding do middle school students use to determine longitude and latitude.

ONLINE MATHEMATICS FOR ADULT EDUCATION: A DESIGN EXPERIMENT FOR GEOMETRY LEARNING THROUGH GEOGRAPHY CONTENT INTEGRATION

Jesus Salinas
CCH-UNAM/CUAED
jesus.salinas25@gmail.com

Veronica Hoyos
UPN-Mexico
vhoyosa@upn.mx

Introduction

In the work that we are reporting here we have advanced in the identification of some characteristics of a *Geometry and Geography* course, which is part of an online educative program of high school called *BUNAM* (see http://www.bunam.unam.mx/). This course is offered to an adult population that are conformed by Mexican immigrants, older than 30 years old and that work abroad of their original places where they look for better conditions of life. Adults at the online *BUNAM* program care for having better levels of certification in education and at work.

Research Objective

This work is a first phase of a project of exploration around the impact of a cycle of task design on the improvement of online adult learning of geometry. In this phase we specifically carried out a cognitive analysis of the tasks belonging to the mentioned course, and a classification of students' responses. For the second phase of the project we have planned to upload at the platform of the program some founded modifications of the analyzed tasks to come back to see students performances about it.

Data, Analytical Frame and Some Conclusions

We classified student answers under two taxonomies that were taken into consideration due to their compatibility: the SOLO taxonomy (Structure of the Observed Learning Outcome) developed by Biggs y Collis (1982), adapted to analyse different types of tasks that are used mostly to teach Geography; and the van Hiele model for geometric thinking (1956, 1986), which has been used to describe a progressive thinking of students (Blair, 2004). For example, one of the tasks for students to answer is the following: "Explain what scientific validity had provided the evidence that Aristotle gave on the curved shape of the Earth". We found here different SOLO levels in the students' answers. Finally, this work shows the potential that digital learning management systems (LMS) have for mathematics education research in relation with the analysis and design (and later incorporation) of convenient changes to proposed tasks in online educative programs. It could be observed that students' answers on the mentioned task were mostly based on reading comprehension. Nevertheless, it is important to note that a response that goes further from a repetition of what Aristotle said would mean that students have some notion of what a scientific proof is. In that way they should have to analyze the given material and select the relevant information to explain how scientifically correct are the arguments proposed by Aristotle to confirm that the Earth's shape is spherical. Without discussing what is understood here by scientific proof, we have considered as a right answer the one that combines the two main aspects of observation and theory, because it would be more complete; and in general terms we can say that a scientific proof consists in contrasting through an empirical way a sentence that is part of a theory. CHARACTERIZATIONS OF MEASUREMENT ACROSS TEACHER TEXTBOOKS

Visala Rani Satyam
Michigan State University
rani.satyam04@gmail.com

Keywords: Measurement, Curriculum Analysis, Elementary School Education, Teacher Education-Preservice

Studies have shown that young children struggle to understand and master measurement concepts (Outhred & Mitchelmore, 2000; Battista, 2004). One avenue for analyzing the content that students learn is to focus on mathematics textbooks for pre-service teachers (McCrory, 2006). Textbooks for teachers largely define the content and knowledge that a pre-service teacher will pass on to their students. My research question is: How do elementary mathematics textbooks for teachers define measurement concepts? Furthermore, how can these definitions be characterized?

I analyzed 6 elementary mathematics textbooks, from a range of authors, and collected definitions for measurement, length, area, volume, and capacity for each textbook. I examined definitions for a discrete or continuous conception of measurement, as a framework. A discrete conception of measurement refers to measurement in terms of units. A continuous conception refers to the entire distance or space, not in terms of discrete units. The coding scheme consisted of coding definitions as discrete, continuous, or integrated. Definitions were coded as discrete if they used the word *unit*, continuous if they referred to the general space, and integrated if the definition contained references to both unit and general space.

I found that the definitions fell along a spectrum of discrete to continuous. The definitions did not fall neatly into purely discrete or continuous conceptions. For example, one textbook's definition for measurement could be "more" discrete than others. Definition characterizations were also consistent throughout each textbook, meaning that a textbook that provided a discrete definition of measurement typically followed through with a discrete definition of length. Further work should be done to refine this discrete to continuous spectrum. The results of this curriculum analysis are an example of one way to characterize textbook definitions. The results also have implications for why students struggle with measurement, if there are radically different ways of explaining measurement depending on the textbook.

TEACHERS' KNOWLEDGE AND REASONING WHILE SOLVING MATHEMATICAL KNOWLEDGE FOR TEACHING GEOMETRY ITEMS

Rachel Snider
University of Michigan
rsnider@umich.edu

Patricio Herbst
University of Michigan
pgherbst@umich.edu

Keywords: Mathematical Knowledge for Teaching, Geometry and Geometrical and Spatial Thinking, Teacher Knowledge

Mathematical Knowledge for Teaching (MKT) (Ball, Thames, & Phelps, 2008) has been heavily studied at the elementary and middle school levels. Researchers have only begun to investigate MKT at the secondary level (Herbst & Kosko, 2012, McCrory, et al., 2012). This current study focuses on teachers' MKT for secondary geometry and examines knowledge in three of the domains identified by Ball et al. (2008), knowledge of content and teaching (KCT), knowledge of content and students (KCS), and specialized content knowledge (SCK). In particular, the study seeks to answer the question: What knowledge and reasoning do teachers use in solving MKT-Geometry problems?

Nine geometry teachers, with 4 to 29 years of experience, were interviewed one-on-one while solving nine MKT-Geometry items, three problems in each domain: KCT, SCK, and KCS. Teachers read questions aloud and talked through their thinking while solving. Percents correct for the items ranged from 11% to 100% and are reflective of difficulty levels from a pilot study (Herbst & Kosko, 2012).

Teacher reasoning was based on pedagogical experiences, knowledge of students, and mathematical knowledge. While each problem can be solved using knowledge of its domain, teachers used extraneous information, both details in the problem and other categories of knowledge, that sometimes led them to incorrect answer choices. For example, in one item, four student solutions are presented for finding the measure of an inscribed angle based on other properties in the diagram. The teachers were asked to identify the incorrect solution, in which the student solves for an unrelated angle, which happens to have the same measure as the inscribed angle. The other three correct solutions provide varying levels of detail. While this item measures SCK and only requires knowledge of circles and angles to be solved, several of the teachers' expectations for explanation in student work led them to pick the wrong choice. The incorrect student work was very detailed, but made a jump in logic by connecting two unrelated angles. One teacher acknowledged that the incorrect answer was incorrect, but despite this, chose the shortest correct answer as incorrect because it was significantly less detailed. In fact, three of the nine teachers chose the shortest answer, because even though it was correct, they did not believe the student provided enough explanation. Full results will be displayed on the poster.

The role of the body, particularly gesture, in supporting mathematical reasoning is an emerging area of research in mathematics education. In the present study, we examine undergraduate students providing a justification for a task about a system of alternating gears, which involves concepts of number relating to even/odd patterns. Some participants were directed to perform gestures relevant to alternation and parity before attempting their justification, while others were not. Although these directed actions did not seem to influence the gestures participants used to solve the problem, we found an important relationship between gesture and mathematical reasoning. In particular, certain types of gestures during problem solving were associated with valid justifications. This research provides insight into the link between action and mathematical reasoning, and has implications for supporting students' proof activities.

Keywords: Cognition, Learning Theories, Reasoning and Proof

Learners display their mathematical thinking—and even engage in mathematical reasoning—with their bodies as well as their minds. Recent theoretical work in education and psychology has sought to broaden researchers' and educators' perspectives to address the role of the body in mathematical thinking and learning. In this research, we adopt this perspective to explore the role of learners' actions during proof and justification activities. Specifically, we investigate the connections between learners' *gestures* and their *justifications* as they talk aloud while attempting to solve a problem about an underlying numerical pattern presented in a gear-system task. By investigating how body movements relate to different forms of mathematical reasoning, we can better understand students' thinking and consider novel ways to support the construction of valid mathematical justifications. We contribute to *broadening perspectives on mathematics thinking and learning* by detailing a connection between specific gestures and types of proof that challenges the concept of mathematics as a disembodied system.

Theoretical Framework

Action and Gesture

An embodied cognition perspective highlights reciprocal connections between actions and cognition (e.g., Glenberg, 1997; Goldin-Meadow & Beilock, 2010). Specifically, these theories suggest that actions do not simply externalize the output of cognitive processes, but may also directly influence and cause changes in cognition and learning (e.g., Shapiro, 2011). Because this view postulates that actions and cognition are intrinsically linked, it stands to reason that there may be an association between an individual's actions and his or her performance on tasks requiring insight and

problem solving (e.g., Thomas & Lleras, 2009). Research has shown that actions play an important, and potentially vital, role in the learning and using of mathematics concepts and procedures -- from the spatial bodily orientations that represent early concepts of number (Dehaene, Bossini, & Giraux, 1993) and the use of fingers in early counting (Alibali & DiRusso, 1999; Saxe & Kaplan, 1981), to the concrete and perceptual dimensions of mathematical symbols (Landy & Goldstone, 2007). Action can also be an important way to "ground" (Goldstone & Son, 2005) abstract mathematical ideas in students' experiences. Physically-grounded actions and manipulations of real and virtual objects can help students understand concepts like proportionality (Abrahamson & Howsin, 2010), fractions (Martin, 2009), and algebra (Nathan, Kintsch, & Young, 1992). It is clear that actions contribute to mathematical thinking.

One specific type of action that is of special interest to educators is *gesture* –the spontaneous hand movements that speakers produce as they talk. Recent theoretical work suggests that gestures manifest mental simulations of actions and perceptual states (Hostetter & Alibali, 2008). Even though gestures do not physically manipulate the environment, growing evidence suggests that the experience of producing gestures can directly influence cognition (Alibali & Kita, 2010; Beilock & Goldin-Meadow, 2010; Goldin-Meadow & Beilock, 2010). Gestures that represent mathematical objects may serve an important function of grounding mathematical ideas in bodily form (Alibali & Nathan, 2007; Nathan, 2008), and they may also communicate spatial and relational concepts (Alibali, Nathan, & Fujimori, 2011). Moreover, speakers' gestures may reveal unique aspects of thought that are based in perception and action, and that may be crucial to their reasoning about the ideas they communicate (e.g., Alibali & Nathan, 2012; Chu & Kita, 2011). Thus in mathematics, gestures not only can provide a window into students' thought processes; they can help students to represent and understand key ideas and relationships. This may be especially true in mathematical tasks that involve spatial reasoning.

Mathematical Proof and Justification

In the study presented here, we investigated how gesture is related to the type and quality of mathematical reasoning in the task of creating a justification for a mathematical task involving an underlying even/odd pattern. Our theoretical framework for conceptualizing mathematical proof and justification is based on Harel and Sowder's (1998) work, which states that producing a proof involves removing doubt about the truth of a conjecture, both from oneself and from others. Harel and Sowder further distinguish between three major subsets of proof: external conviction, empirical, and analytical. The first orients around the production of self-satisfying proofs that rely upon external resources, such as textbooks or teachers, which we do not focus on in this study. The second subset, empirical, involves validating conjectures using physical facts or perceptual experiences. Finally, the third subset, analytical, "is one that validates conjectures by means of logical deductions" (p. 258).

We rely upon a specific type of proof in this third subset, *transformational*, which Harel and Sowder define as proof activities that are characterized by generality and abstraction, deliberate mental operations, and image transformations. We also utilized a specific type of proof in the empirical subset, referred to as *perceptual* proofs. These proofs involve mental images similar to transformational proofs, but which Harel and Sowder contrast by noting that perceptual proofs "consist of perceptions and a coordination of perceptions, but lack the ability to transform or to anticipate the results of a transformation" (p. 255). Given that transformational and perceptual proofs both involve images, and given the close ties between gestures and mental images (e.g., McNeill, 1992), Harel and Sowder's proof scheme is particularly well suited to our approach.

Gear-Parity Problems

We examined the justifications participants provided as they attempted to generate and justify a conjecture about a system that follows the underlying numerical pattern of *parity*, which we here instantiate with a system of interlocking gears. Parity in this context refers to the idea that in systems

with an odd number of gears, the final gear turns in the same direction as the initial gear, while in systems with even numbers of gears, the first and last gear turn in opposite directions.

When provided with a static display of a row of gears or asked to imagine such a system, participants typically begin solving the problem by simulating the turning of the gears with their hands (Schwartz & Black, 1996). After producing such rotating gestures, many participants shift to a new approach during which they note that the gears move in an alternating sequence. Past work with both undergraduates and young children has shown that concentrated, accurate simulation of the gear movements predicts the transition to recognizing such *alternation* (Boncoddo, Dixon & Kelley, 2010; Trudeau & Dixon, 2007). Thus, participants' ability to abstract the underlying mathematical relationship in the gear system seems to be related to their actions, and in particular, to the action of repeatedly tracing multiple circles as they think about and solve the problems. When a participant discovers parity, they display an understanding that the direction of movement of the final gear is related to the number of gears in the system.

Thus, reasoning about conjectures involving gear systems are of interest to mathematics education because they manifest the abstract parity rule that is a key component of understanding number systems. Moreover, gear systems are often utilized as a grounding context in mathematics lessons focusing on ratio, proportions, and linear functions (e.g., Lobato & Ellis, 2010; Ellis, 2007). For example, Ellis (2007) utilized gear systems in a teaching experiment on linear functions in order to give students a real-world situation within which to learn about linear relationships. Thus, gear systems embody important mathematical ideas, and examining how students solve such problems provides insight into how teachers can support their thinking about these ideas in the mathematics classroom.

Research Questions

In this study, we focus on the gestures that speakers produce when reasoning about a gear-parity conjecture. We first examine whether the types of gestures participants produced while thinking aloud about the conjecture varied depending on the specific actions they were directed to perform prior to being given the conjecture. Second, we examine whether the types of gestures participants produced during justification of the conjecture were related to the type and quality of the justifications they provided. Thus, our first research question was: Is the nature of students' directed actions *prior* to engaging in proof reasoning related to the nature of the justifications they provide? Our second yet primary research question was: Is the nature of students' gestures *during* proof reasoning related to the nature of the justifications they provide? This research provides insight into the link between action and mathematical reasoning, and has implications for supporting students' proof activities.

Methods

Participants

Participants were 120 undergraduate students enrolled in a psychology course at a large Midwestern university. Their average age was 19.6 years (*SD* = 1.08) and 51% of the participants were female.

Procedure

As part of a larger study, each participant was asked to solve a number of problems, including gear-parity, geometry, and transfer tasks; in this paper we focus only on the gear-parity problems. Participants were asked to think aloud (Ericsson & Simon, 1998) as they solved the problems. Instructions and interviewer prompts were standardized, and tasks were presented on an interactive white board. Participant data was coded separately for justifications and for gestures, as detailed later in this section.

Before solving the gear-parity task, participants were randomly assigned to perform actions that were either relevant or irrelevant to providing a correct justification for the conjecture (see Table 1).

The relevant actions were based on previous studies that have shown that before participants discovered knowledge of the underlying numerical relationship of parity in the gear system, they typically use a strategy called "alternation," in which they abstract the relation that adjacent gears move in alternating directions (Trudeau & Dixon, 2007). In particular, relevant actions involved students tapping back and forth on a screen, to model alternation. For participants who performed relevant actions, we also varied whether participants were told that the relevant actions they performed were related to the gear problem, which we call *projection*. Participants who received projection were explicitly informed that the tapping actions related to the solution to the problem, while other participants were not informed that their actions had any relevance. Finally, half of the participants performed small actions that were entirely within the periphery of their gesture space, while the other half performed larger actions that extended outside the periphery of their gesture space (McNeill, 1992). This factor did not affect participants' success at abstracting the underlying mathematical relationship, so we do not discuss it further in this report.

Justification Coding

A coder blind to experimental condition used the proof categories from Harel and Sowder (1998) to code participants' justifications on the gear task. For our purposes, participants' justifications were coded as *analytical>transformational* if they acknowledged that connected gears form an alternating pattern of motion, and that the turning direction of the final gear is based on whether the total number of gears in the system is even or odd. We also extended the category of *empirical>perceptual* proof to account for a problem-specific nuance, distinguishing between *perceptual with alternation* and *perceptual without alternation*. Perceptual with alternation justifications included an understanding that the gears move in an alternating pattern, but the participant failed to acknowledge parity. Perceptual without alternation justifications included participants making comments that demonstrated a belief that the gears all turned in the same direction or that the last gear would turn in the same direction as the first gear, regardless of the number of gears present. Finally, the justifications of the participants who were unable to come up with a justification for how the gear system would turn were coded as *don't know*.

Table 1: Gear Conjecture and Directed Actions

Conjecture	An unknown number of gears are connected in a chain. You know what direction the first gear turns, how could you figure out what direction the last gear turns? Provide a justification as to why your answer is true.	
Relevant actions	<u>Large Actions</u>: Participant alternates between tapping a blue and yellow diamond placed an arm span apart on the Interactive White Board with their palm. 	<u>Small Actions</u>: Participant alternates between tapping a blue and yellow diamond placed a hands-length apart on the Interactive White Board with their index finger. Irrelevant actions	<u>Large Actions</u>: Participant taps only the blue diamond with their palm.	<u>Small Actions</u>: Participant taps only the blue diamond with their index finger.

Gesture Coding

A coder who was blind to experimental condition watched and coded each participant's session without sound in order to classify gestures based on their form while uninfluenced by the verbalizations that accompanied those actions. Participants' gestures were classified into three categories: *rotating* gestures, *ticking* gestures and *other* gestures. These categories were identified as important based on previous studies of undergraduates solving gear-system problems (e.g., Alibali,

Spencer, Knox & Kita, 2011; Schwartz & Black, 1996; Trudeau & Dixon, 2007). *Rotating* gestures depicted one or more gears turning, typically using either one finger or the whole hand. Rotating gestures were further classified as depicting a single gear, multiple gears turning in the same direction, or multiple gears turning in alternate directions. *Ticking* gestures were defined as gestures that displayed a series of ticks, taps, or other discrete movements, typically produced using one finger or the whole hand and moving across space. Gestures that did not fall into either of these categorizes were labeled as "*other*" and descriptions of these gestures were recorded for further future analyses. Other gestures that we noted included beats, single points, and gestures that depicted movements other than rotating or ticking.

Results

Did participants' gestures vary by condition?

We first examined whether participants in the three conditions (relevant action with projection, relevant action without projection, and irrelevant action) varied in the types of gestures that they produced. First, participants were classified by whether they ever produced rotating gestures. Second, participants were then grouped according to whether they ever produced multiple rotating gestures with alternation, or only produced rotating gestures without alternation. As noted above, alternation is of particular importance to the gear-parity conjecture. We expected that more participants in the relevant-action conditions (regardless of whether they also received projection) than in the irrelevant-action condition would produce gestures that manifested alternation. Specifically, we hypothesized that tapping back and forth embodied the alternation relationship found in the gear system, which we expected to be subsequently manifested in the gestures that participants produced during justification. As seen in Table 2 (leftmost column), this was numerically the case. However, the difference across conditions was not significant.

Table 2: Percentage of Types of Gestures Produced by Participants in Each Condition

	Rotating Gestures		
Condition	Any multiple with alternation	Other (no multiple with alternation)	Ticking Gestures
Irrelevant	53	18	20
Relevant + Projection	55	30	8
Relevant	68	23	25

A third coding dimension classified participants in terms of whether they ever produced ticking gestures. We had anticipated that more participants in the relevant-action conditions than in the irrelevant-action condition would produce ticking gestures, since the relevant actions they had performed involved ticking back and forth. Instead, more participants in both the relevant and irrelevant conditions produced ticking gestures than did participants in the relevant-action-plus-projection condition. The difference across conditions in the proportion of participants who produced ticking gestures approached significance, $\chi^2(2, N = 120) = 4.50$, $p = .105$.

Thus, we did not find statistically significant relationships between action condition and patterns of gesture production. However, trends in the data suggest that the relevant actions may have encouraged participants to acknowledge alternation, and that projection may have inhibited ticking gestures during the justification.

Were variations in gesture associated with variations in justifications?

Given that variations in gesture production amongst conditions were not significant, we collapsed across conditions in order to examine whether participants' gestures during problem solving were associated with the quality of the justifications they provided. Figure 1 displays the percent of

participants who provided each type of justification, as a function of the type of gestures participants produced during their explanation. Very few participants produced ticking gestures only ($N = 1$), or ticking gestures with non-alternating rotating gestures ($N = 2$), so these categories are not displayed in the figure. The number of participants in the other categories ranged from 18 to 52.

As seen in Figure 1, participants who produced rotating gestures with alternation (the right two bars) were much more likely to provide valid, transformational justifications than were participants who did not produce such gestures (the left two bars), $\chi^2(1, N = 117) = 18.71, p < .001$ (83% vs. 43%). Importantly, producing rotating gestures *with* alternation was more strongly associated with transformational justifications than was producing rotating gestures *without* alternation (i.e., single circles, or multiple circles that did not alternate direction), $\chi^2(1, N = 78) = 7.13, p = .007$ (comparing the middle two bars to one another, 46% vs. 15%). In addition, participants who produced ticking gestures *along with* rotating gestures with alternation (the rightmost bar) were slightly more likely to provide transformational justifications than were participants who produced rotating gestures with alternation without ticking gestures (the center right bar) (67% vs. 54%). However, this difference was not significant.

Finally, among participants who produced perceptually-based justifications (the two light gray categories), participants who produced rotating gestures with alternation were more likely to incorporate alternation into their justifications than were participants who did not produce such gestures (the left two bars), $\chi^2(1, N = 68) = 18.50, p < .001$.

In sum, producing rotation gestures with alternation was associated with expressing more sophisticated justifications. Participants who produced rotation gestures with alternation were more likely to express transformational justifications, and, if they expressed perceptual justifications, they were more likely to incorporate alternation.

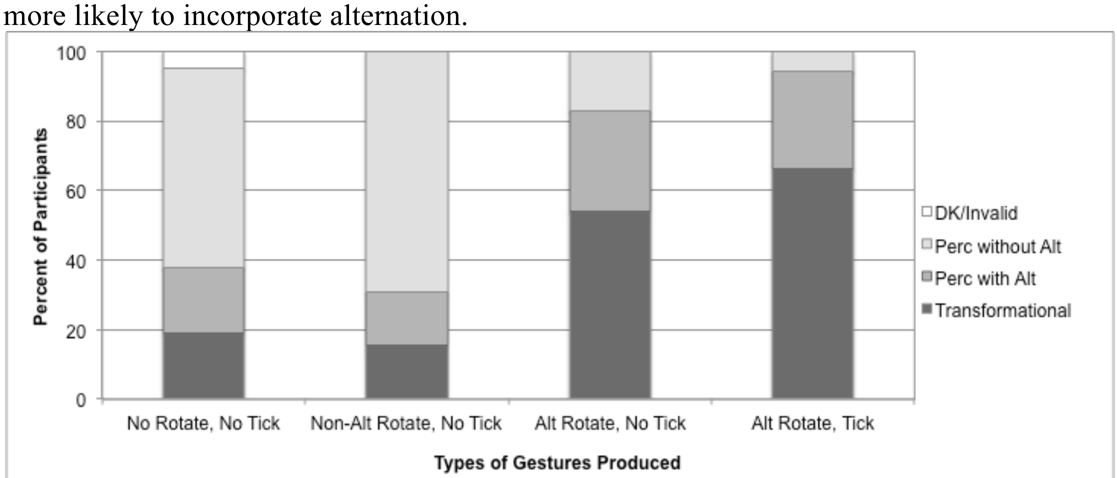

Figure 1: Percent of Participants who Provided Each Type of Justification as a Function of the Types of Gestures Produced

Conclusion and Implications

This study investigated the gestures participants produced when generating and justifying a conjecture about a gear system. Specifically, we found that participants who produced multiple, alternating rotating gestures were the most likely to solve the problem utilizing transformational justifications. This finding aligns with past research indicating that simulation of the gear movements was associated with participants' generating an alternation approach (Boncoddo et al., 2010). Additionally, this finding adds to the body of work that shows that gesture is closely related to, and can perhaps affect, learners' approaches to mathematical justification. The fact that certain, identifiable gestures were closely aligned with valid justifications highlights the importance of

considering both speech and gesture when examining mathematical reasoning. Producing these gestures may be a key aspect of students' understanding and adopting the mathematical insights behind the gear problem.

Participants who produced ticking gestures along with rotating gestures with alternation were most likely to produce transformational justifications, raising the possibility that ticking motions are a potentially useful form of abstraction for the concept of parity. Rotating gestures and ticking gestures may each play different roles in supporting mathematical reasoning, and when used in combination they may be especially powerful. In this light, it is interesting that participants in the relevant-action-with-projection condition were especially *unlikely* to use ticking gestures. The high rate of multiple, alternating gestures, but low rate of ticking gestures in this condition suggests that projection may have encouraged participants to focus too strongly on the concrete movement of the gears, making it more difficult for them to make the mathematical abstraction. In other words, being directed to perform alternating ticking gestures and being explicitly told of their relevance to the gear problem may have made abstraction to the even/odd pattern more difficult, as it focused participants on concrete, perceptual aspects of the situation (e.g., Kaminski, Sloutsky, & Heckler, 2005).

This work has important implications for broadening perspectives on mathematical thinking and learning. While students in mathematics classrooms may or may not be involved in gear tasks specifically, we have shown that certain kinds of gestures can be strongly associated with producing transformational proofs. Thus, it may be beneficial for teachers to encourage students to gesture while reasoning, and to pay close attention to students' gestures to look for key aspects of their reasoning processes and current levels of understanding.

INDIVIDUAL ADHERENCE TO INQUIRY-ORIENTED NORMS OF DEFINING IN ADVANCED MATHEMATICS

Paul Christian Dawkins
Northern Illinois University
dawkins@math.niu.edu

This study investigates students' individual patterns of adherence to a norm for creating and assessing definitions in an undergraduate real analysis classroom. Our findings indicate that, though all students understood the expectation to define, students differed in their individual adherence to the norm depending upon their perception of the nature of the defining activity and their associated role in the classroom. While some students primarily attributed the expectation to define to the teacher (taken-as-expected), others understood the expectation as truly shared as a means toward classroom learning (taken-as-beneficial). A third group of students internalized the expectation as a means of their membership in the mathematical community (taken-as-meaningful) and were therein willing to challenge the professor's defining choices in light of their values for mathematical defining.

Keywords: Advanced Mathematical Thinking, Reasoning and Proof, Post-Secondary Education

Introduction

For some time, the Emergent Perspective framework (Cobb & Baursfeld, 1995; Yackel & Cobb, 1996) has provided a fruitful set of tools for documenting collective learning phenomena within mathematics classrooms. One of the primary strengths of their framework is a refusal to dichotomize psychological and sociocultural phenomena, instead viewing each as an analytical perspective for which the other provides a necessary context. As a result of this balanced approach, research points to strong connections between collective constructs (classroom norms, sociomathematical norms, or mathematical practices) and individual constructs (mathematical beliefs or conceptions; Yackel & Rasmussen, 2002).

However, the university classroom structure places a larger onus of mathematical learning on students' time outside of class. This indicates that the research community also must consider exactly how classroom norms and practices influence students' mathematical activity outside the classroom. Thus, this paper seeks to address the following questions:

1. In an undergraduate real analysis course characterized by inquiry-oriented norms for defining, what are students' individual patterns of participation in the norms during class meetings and while working on class assignments outside the classroom?
2. How do students' patterns of participation interact with their beliefs about the purpose(s) of shared defining activities and students' role in advanced mathematical activity?

The current investigation draws from classroom observations and interviews with volunteer students from two different inquiry-oriented real analysis classes to answer these questions. These classes, taught by the same professor, adopted an inquiry-oriented approach to defining in the sense that the class treated definitions as "under construction." The class consistently discussed how and why mathematicians define concepts in the way they do. My findings indicate that even after certain mathematical expectations became "taken-as-shared" norms, students display individual differences and shifts in their perception of the source of the expectation: from external, to generalized, to internal. These categories extend the psychological lens of the Emergent Perspective as it relates to students' mathematical activity beyond the classroom.

The Emergent Perspective framework

The Emergent Perspective is especially useful for providing rigorous and actionable means of defining what it means for a collective (members of a class or small group) to "know" something as well as characterizing essential differences between classroom cultures. Drawing from the interactionist perspective of sociology, the framework recognizes that the behavioral regularities of culture are constituted through interpersonal interactions (Blumer, 1969; Prus, 1994). While no one person creates culture, participation in cultural practices simultaneously reinforces those cultural elements. The emergent framework identifies three broad categories of cultural elements pertinent to the mathematics classroom:

1. taken-as-shared expectations for participating in the classroom are *classroom norms*,
2. taken-as-shared criteria by which participation is deemed acceptable are *sociomathematical norms*, and
3. taken-as-shared mathematical activities and associated meanings are *classroom mathematical practices* (Cobb, Stephan, McClain, & Gravemeijer, 2001).

The current study focuses on the first two categories. Examples of classroom norms include explaining and justifying one's reasoning (Cobb, Wood, Yackel, 1993) or presenting proofs and answering questions about them (Fukawa-Connelly, 2012). Examples of sociomathematical norms include mathematical criteria for determining what constitutes acceptable explanation, justification (Yackel & Cobb, 1996), or proof (Fukawa-Connelly, 2012).

Classroom norms begin as expectations for mathematical activity that are endorsed by members of a classroom. Once members of a classroom community: (a) act in accordance with the expectation, (b) respond against breaches of the expectation, and (c) cease to question adherence to the expectation, then that expectation is "taken-as-shared" among that community. Norms that satisfy these criteria can be considered "known" within the classroom not because of their presence or establishment within individual minds, but rather because of their interactively legitimized functionality in classroom activity.

The Individual Lens of the Emergent Perspective Framework

Many researchers link elements of collective understanding to elements of individual understanding such as students' beliefs and community values (Cobb et al., 2001). Fukawa-Connelly (2012) investigated classroom norms in an undergraduate abstract algebra class both via classroom observation and delayed student interviews, and found a large level of agreement between students' descriptions of classroom norms and his analysis of classroom videos. Levenson, Tirosh, and Tsamir (2009) instead noted differences between teacher and student perceptions of classroom norms. However, fewer studies compare classroom mathematical culture to students' individual activity outside the classroom. This is because the Emergent Framework was developed for classroom instructional design (Yackel & Cobb, 1996; Cobb et al., 2001). But keeping with the Emergent Perspective's resistance to dichotomizing individual and collective learning, social constructs must inform or situate the investigation of individual learning. The current investigation employs the Emergent Framework in this alternative way.

One question not clearly addressed in prior literature is, "What is a norm prior to it becoming normative?" By standard definitions it would be a contradiction to say one person introduced a norm because norms must be collectively constituted. I use the term *expectation* for a not-yet-taken-as-shared norm, which is somewhat novel though it appears in the Emergent Perspective literature along with terms such as "obliged" (Cobb et al., 2001; p. 133). If students were "obliged" (a form of "obligated") to act in a certain way, this expresses a mutually understood expectation. Once an expectation is mutually understood, it is taken-as-shared. However, another question that arose from analysis of my data is, "By whom is one expected to act in certain ways?" Even if students act to satisfy an expectation and/or reinforce the expectation to one another, they may attribute the expectation to a particular source. I thus distinguish the source of an expectation (or "locus of expectation") from its "taken-as-shared" status in the classroom.

Reform-oriented norms and student autonomy

The literature on sociomathematical norms consistently points to a link between inquiry-oriented norms and students' sense of autonomy and authority in their own learning (Cobb et al, 2001; McClain & Cobb, 2001; Yackel & Cobb, 1996). When students are allowed to negotiate the criteria by which their

activity is mathematically assessed, they may become a "community of validators" (Yackel & Cobb, 1996) rather than relying fully on the external sources. In such cases, students often display greater intellectual autonomy (McClain & Cobb, 2001), which is a direct goal of many instructional reform efforts (Yackel & Cobb, 1996).

Relevant literature

The current study was conducted in undergraduate, real analysis classrooms and thus within the instructional tradition of "advanced mathematical thinking" (Tall, 1991). Being a proof-oriented course, real analysis is part of mathematics majors' enculturation to the mathematical community and its associated processes (i.e. defining, conjecturing, proving). In the classroom, these processes are expressed and guided by norms of classroom activity. The following literature provides insights into the teaching and learning of these mathematical processes.

Students' use of definition

A survey of the definition literature reveals a recurrent dichotomy between two primary ways in which students reason about categories: either a definition describes a preexistent category or it constitutes the set of all exemplars satisfying its conditions. So, either a category suggests a defining property or the property determines the category members. Several studies (Edwards & Ward, 2008; Alcock & Simpson, 2002) observe that while mathematicians act as though definitions are in in the latter category (*stipulated* definitions), many students instead rely primarily on intuitive notions or prototypes (*extracted* definitions). Mathematicians' emphasis upon reasoning from the formal definition stems from the fact that "appropriate use of the definition means that any correct deductions he makes will be valid for all members of the mathematical category" (Alcock & Simpson, 2002, p. 32).

Engaging students in producing or assessing defining activities

Though a student's untrained use of definitions differs from a mathematician's, several studies indicate that students asked to produce or assess definitions often identify standard values for defining. (Zaslavsky & Shir, 2005; Zazkis & Leikin, 2008). These values include clarity, elegance, non-redundancy, and arbitrarity (non-uniqueness). These studies suggest that defining activities simultaneously reveal and help reorganize students' conceptions about defining.

Methods

As this study intended to relate elements of classroom culture to students' independent work outside of class, I simultaneously developed models of classroom activity and students' individual activity. Toward this end, I gathered data including: detailed notes from all class meetings, bi-weekly professor interviews, and weekly student interviews with a group of 4-6 volunteers per semester (two semesters of data are analyzed).

Professor and instructional context

The professor observed in this study is a tenured mathematician at a large, comprehensive, public university in the Southwestern United States. The professor received multiple teaching awards based on student and colleague nominations, including from her previous real analysis students. The classes met for 75 minutes twice per week for 15 weeks. Professor interview questions generally related to: her intentions and expectations for class sessions, her reflections upon class discussions, and her understanding of students' reasoning (to which she paid a great deal of attention). These interviews informed my emerging model of her instructional practice based on her class activities and teaching actions. The flow of the classroom discourse would best be described as a highly interactive lecture with the professor consistently guiding the conversation (Dawkins & Roh, 2011). Though extended student-to-student conversations were less common, the professor consistently re-voiced and championed students' ideas or played devil's advocate for ideas that she found reflective of commonly held misconceptions.

The classroom norms were reform-oriented in the sense that the professor treated elements of the real analysis theory as "under construction". I identified three types of activities by which she invited students to create and assess definitions: defining (a) *portrayed*, (b) *discussed*, and (c) *enacted*. In *defining portrayed* activities, the professor asked students to compare provided definitions against intuitive ideas

or groups of examples. The group accepted or rejected the definitions based on the emerging shared criteria and examples. In *defining discussed* activities, the professor prompted students to reflect on how and why they defined (see Dawkins, 2012 for a detailed description of one such activity). She invited students to question her and the mathematicians "who wrote the books" to reflect upon definers' intentions. In *defining enacted* activities, students had to produce definitions to turn in or present to the class, often with heavy scaffolding from a previous definition. Through these activities, the professor endorsed the norm that "Students are obliged to create and assess mathematical definitions or conditions within definitions" (or the "norm of defining" for brevity).

Interview participants and analysis

During two semesters of one professor's real analysis course, I solicited a small group (4-6) of volunteers to participate in a sequence of 7-9 weekly interviews regarding their learning in the course. I analyze the activity of seven students (5 from semester 1 and 2 from semester 2), based on the number of participants who provided sufficient data for categorization relative to the research questions. The interviews (a) invited students to reflect on and explain parts of the classroom discussion and (b) documented student work on homework tasks to simulate their independent learning. The professor's *defining discussed* activities aided the study because the first type of interview question naturally extended the classroom dialogue. For instance, after spending a class period on the notion of cluster point without providing a ratified definition, the professor asked whether the class preferred that she provide a definition up front. She drew attention to her intentions in discussing these conceptual issues rather than dispensing pre-formulated knowledge. When I asked questions about this same practice, students appeared to report their reflections about the class dialogue in response to the classroom discussion (or in response to the professor) rather than as an artificial product of the interview environment.

All interviews were audio recorded, transcribed, and coded using a grounded theory open-coding protocol (Strauss & Corbin, 1998) in the NVivo program for qualitative data analysis. I analyzed and coded all cases of students' classroom and interview activity related to the process of mathematical defining. The categories related to a student's: (a) personal concept definitions (PCD), (b) understanding of examples or concepts related to key definitions, (c) ability to produce novel limit definitions (of the form $\lim_{x\to\blacksquare} f(x) = \blacksquare$), (d) choices regarding the professor's defining activities or challenges to her defining choices, (e) perceptions of the values of mathematical defining, and (f) sense of vestment in defining. The emergence of the last three categories motivated the current report. Categories (d) and (f) revealed some students' sense of intellectual autonomy and authority. The students' autonomy often appeared in tandem with particular patterns in their perception of the defining activity as shall be discussed.

Results

Analysis identified three primary patterns of students' adherence to the norm in their individual mathematical activity. These patterns of adherence are not mutually exclusive, being that one student shifted patterns over time, but they differ according to students' (a) understanding of the intent of defining activities, (b) beliefs about the nature of mathematical definitions, and (c) their locus of expectation for the norm of defining. I define *adherence* as a student's individual behavior in relation to a classroom norm, which is the psychological correlate to the collective notion of *participation*. By "behavior," I include cognitive activity in the classroom and isolated activity outside the classroom.

Non-adherence

Vincent was the only participant who clearly displayed a pattern of *non-adherence to the norm of defining*. *Non-adherence* is defined as a willing abstinence from mental or enacted defining despite understanding of the norm of defining. Soon after a lecture in which the class discussed defining function limits without a ratified definition, Vincent and the interviewer (also the author) had the following interchange (March 26):

I: Usually we talk one class period about a subject, and then we define it the next class period […] Why do you think she does that?

> *V*: Maybe cause she wants us to all try and develop our own definition of it, then once we come to the next class, she is going to show us the definition that is accepted by the people who argue over the definition. I don't know… I mainly just wait for her to define it for me.
> *I*: Why is that?
> *V*: Because, I don't know. I guess, lack of motivation to do it on my own because I know she is going to do it. […] When she finally gets us set with a solid definition, sometimes I will look at the other stuff that she was talking about and try to relate 'em and everything. I don't go and find out on my own so much.

Vincent understood the expectation for students to reason about defining, but his perception of the activity kept him from adhering to the norm. Vincent's locus of the expectation was the professor. Though the professor invited students to consider various definitions, Vincent thought of "the definition that is accepted" as a single answer he wanted the teacher to provide. This is more in line with traditional norms of advanced mathematics instruction (Weber, 2004). Vincent located the source of mathematical authority outside of himself, not identifying himself with the "people who argue over the definition." He also expressed lack of motivation or necessity for adhering to the norm. Vincent was the only study participant who had to retake the course.

Peripheral adherence

Over time, Vincent shifted his pattern of adherence to the norm. On April 8, he reported (after a *defining enacted* activity), "She had us try to define in class, which I thought was pretty interesting […] And that was kind of fun, I liked that cause […] I don't really sit there and try to define it because I would rather just look it up, and it was actually different trying to define it and getting pretty close to what was in the book." Vincent consciously noted his shift from *non-adherence* to *peripheral adherence* to the norm. Peripheral adherence is defined as mental or enacted participation in defining as a pedagogical activity toward the end of learning pre-existing mathematical content. Vincent maintained an external sense of authority comparing his defining activity "to what was in the book", but Vincent showed a strong attitudinal shift toward adhering to the class' expectation on his behavior. He later reported that his shift toward independent defining grew from frustrations with having to depend upon his classmates' understanding.

Four of the study participants (Aerith, Celes, Tidus, & Vincent) exhibited *peripheral adherence* to the norm of defining. These students interpreted the defining activity as didactical in nature. Accordingly, they often retained a view that the formal definition was fixed by outside authority, and that they needed to understand those definitions. However, *peripheral definers* generalized the locus of expectation to the classroom. For instance, Tidus described the teachers' intentions in defining portrayed and enacted activities saying: "Instead of just being given information and trying to regurgitate, you're [trying to] see how you got to that point and then it seems to stick in your head more when it's done that way" (Dec 12). Later, he described the class' defining activities saying,

> "We didn't really have anything concrete that we knew without a doubt was true, we were just thrown some ideas, given some actual applications or examples. […] And then all of a sudden we get to the definition, and now it's not just this bland definition sitting on the board. We actually see why it's, why that's being defined, what it's used for, and there's a different appreciation for it. [When the professor poses T/F questions] we are gonna' actually test our and see if we actually understood it or not. And then the homework, of course we get to work out of class and use it some more, try to understand it some more. And then those [expletive] tests to see if we actually got it or not." (Dec 12)

Tidus' comments exemplify peripheral adherence in several key ways. First, he centers his justifications of the activity in terms of improved understanding and recall. He interprets the sequence of classroom activities (discussing, defining, true-false questions, homework, exams) as a connected means of developing and assessing learning. Tidus thus frames (Goffman, 1974) the activity within a didactical structure. Next, though he used a singular pronoun during the first quote ("you") to describe recall, he

also regularly used a plural pronoun ("we") indicating a sense of communal activity and expectation in the classroom. Though the norm was *taken-as-shared,* Tidus' locus of expectation was generalized to the whole class. This differs from Vincent's identification of the professor as the source of expectations. However, *peripheral definers* tended to maintain an external sense of authority, consistent with the didactical frame. Their perceived role in defining is as learners of mathematics known or developed by experts.

Authoritative adoption

Three of the study participants (Cyan, Edgar, & Ronso) displayed *authoritative adoption* of the norm of defining. Authoritative adoption is defined as mental and enacted participation in the norm in accordance with an internal sense of authority in their mathematical activity. These students framed defining as their participation in advanced mathematical activity, implying that they were members of the mathematical community. Authoritative adoption evidenced itself by students' tendency to use the personal pronoun ("I") with respect to their defining activity and their willingness to contest the professor's mathematical claims. Both such behaviors suggest an internalized locus of expectation. All three authoritative adopters explicitly questioned the professor's defining choices based on some meta-mathematical criteria. For example, both Cyan and Ronso expressed dissatisfaction with the professor's choice to include the textbook's requirement that function domains must contain some interval (a, ∞) to have a limit of the form $\lim_{x\to\infty} f(x) = L$. Both students asked why functions defined on the rational numbers or the integers could not have such a limit. They argued instead that the book's definition violates the criterion that mathematical definitions should be sufficiently general within the local body of theory. These students also seemed to properly coordinate between treating definitions as *extracted* while defining and *stipulated* while proving. Like peripheral adherers, adopters said defining helped them learn. However, they acted primarily within a mathematical frame rather than an instructional frame. Adopters were the top-performing study participants in the courses.

Discussion

Summary of categories and constructs

While all students appeared to perceive the shared nature of the norm of defining, students differed in their locus of expectation, sense of authority, and their frame for the defining activity. The non-adherer Vincent located both the expectation and mathematical authority with the professor or other experts. Peripheral adherers like Tidus generalized the locus of expectation to the classroom viewing defining as a shared practice. However, they maintained an external sense of authority consistent with their pedagogical frame for the shared defining activity, which positioned them as learners of the mathematical understandings held by the professor. Authoritative adopters like Ronso or Cyan exhibited an internalized locus of expectation and source of authority, evidenced by their willingness to challenge the validity of the professor's defining choices. Table 1 organizes the characteristics of each category.

To clarify this diversity of adherence to the norm, I offer three new sub-constructs. For non-adherers, the practice is *taken-as-expected* (TAE), meaning the norm's value is extrinsic (imposed) in the sense of being a means toward the goal of satisfying the professor. For peripheral adherers the practice held intrinsic, secondary value, which I call *taken-as-beneficial* (TAB). In the case of TAB, the norm holds intrinsic (personal) value for the individual, but the benefit is derived from the value for learning and is thus secondary. For authoritative adopters, defining held an intrinsic, primary value, and is thus *taken-as-meaningful* (TAM). Once a student feels personally vested in defining as part of their mathematical identity, they intrinsically value the process itself in addition to its other benefits. These constructs are likely inclusive or nested inasmuch as authoritative adopters acknowledged that defining helped them learn (TAB) and understood the professor's expectations. However, intrinsic values generally prove stronger and more durable than extrinsic values suggesting why authoritative adopters displayed more detailed defining activity outside the classroom context. These finer distinctions extend and clarify the Emergent Perspective literature's claims that inquiry-oriented norms help promote students' development of compatible individual mathematical beliefs (Cobb et al., 2001; Yackel & Cobb, 1996).

Table 1: Characterizations of Individual Adherence to the Norm of Defining

Category	*Non-adherers*	*Peripheral adherers*	*Authoritative adopters*
Locus of expectation	Professor	Generalized	Internalized
Source of mathematical authority	Professor/ textbook	Professor/ textbook	Self
Frame for defining	Pedagogical (non-beneficial)	Pedagogical (beneficial)	Mathematical
Individual status of the collective norm	TAE	TAE, TAB	TAE, TAB, TAM

Practical contributions

The university classroom structure assumes that a large onus of learning falls on students' time outside of class (traditionally in a 3:1 ratio). This suggests that understanding classroom activity and the culture therein only accounts for a portion of students' mathematical engagement. It thereby seems important to understand how classroom norms for mathematical practice influence students' mathematical activity beyond the classroom. My findings suggest that the classroom environment strongly influences students' individual activity, but the relationship between collective norms and individual action is more complex than direct correspondence. Factors of affect and identity seemed to strongly influence students' adherence to norms. Vincent's shift in adherence may reveal the positive influence of the classroom environment on his mathematical identity, but further evidence is required in this regard.

I also maintain that advanced mathematics instruction should enculturate students into the mathematical community. Therefore, it is important that students engage in and understand key mathematical practices such as defining. While almost every student reported learning from participating in defining, authoritative adopters also identified values of defining by which they contested the professor's defining activity. As such, they displayed rich understandings of mathematical definitions and expressed personal identification with the community of mathematicians. I hypothesize that these students who internalize the locus of expectation are most likely to adhere to and endorse the norm of defining in their future mathematical activity either as students or teachers (the majority of these students proceeded to graduate studies in mathematics or to secondary mathematics teaching). The ability of students to adhere to such practices beyond the influence of the original locus of expectation (the professor or class) seems a pertinent factor for the "durability of sociomathematical norms" (Van Zoest, Stockero, & Taylor, 2011), and thus warrants further study. The individual sub-constructs to *taken-as-shared* identified in this study should facilitate the continued investigation of such phenomena.

Examples play a critical role in the exploration and proving of conjectures. Although proof has been studied extensively, the precise ways in which examples might facilitate successful proofs are not well documented or understood. Working within a larger set of studies that argue for the value of examples in proof-related activity, in this paper we present a case study of one mathematician's work on a conjecture in which his strategic, intentional use of examples led to a proof of that conjecture. By examining his work in detail, we highlight specific mechanisms by which the mathematician's examples led to successful proof production. These mechanisms shed light on precise ways in which examples can directly lead to proof and inform our understanding of the conceptual landscape of the interplay between examples and proof.

Keywords: Advanced Mathematical Thinking, Reasoning and Proof, Post-secondary Education

Introduction

In much of the current literature on teaching proof in school mathematics (e.g., Harel & Sowder, 1998; Stylianides & Stylianides, 2009; Zaslavsky, Nickerson, Stylianides, Kidron, & Winicki, 2012), example-based reasoning is framed as a limited way of thinking that students should avoid. It is true that ways of reasoning about proof that overly rely on examples can be problematic, particularly if examples are perceived by students as valid substitutes for proofs. We posit, however, that these potential limitations of examples have become so prominent in the proof literature that potentially positive roles of examples in proof have not been sufficiently explored. We suggest that the exploration of productive roles of examples in proof offers significant untapped research potential. Given that examples seem to play an essential role in mathematicians' exploration of conjectures and subsequent proof attempts, example-based reasoning strategies can lead to meaningful opportunities for research, illuminating ways in which examples might be used to support students' proof development.

The work presented here builds on recent attempts to learn more about the roles that examples can play in exploring and proving conjectures across a variety of levels (Ellis, et al., 2012). In this paper, we present a case study, examining in detail one mathematician's use of examples in developing a proof of a novel (to him) conjecture. We highlight specific mechanisms through which examples were used as the mathematician formulated a proof. By narrowing our analysis to one mathematician, we can provide significant mathematical detail, allowing for key insights to be shared about how the mathematician leveraged examples in constructing a proof. Through the case study we seek to inform our understanding of the relationship between examples and productive proof-related activity, and we discuss potential implications for the teaching and learning of proof.

Literature Review and Theoretical Framework

Weber (2008) states that, "investigations into the practices of professional mathematicians should have a strong influence on what is taught in mathematics classrooms" (p. 451). A number of other researchers have studied mathematicians' practices under the assumption that their work might provide valuable insight about these practices more generally. For example, Carlson and Bloom (2005) examined mathematicians' problem solving, and Savic (2012) used innovated technology to study what mathematicians did when they reached impasses in their proving processes. In the domain of examples, Epstein and Levy (1995) contend that "Most mathematicians spend a lot of time thinking about and analyzing particular examples," and they go on to note that "It is probably the case that most significant advances in mathematics have arisen from experimentation with examples" (p. 6). Alcock and Inglis (2008) similarly argue that there is often a complex interplay between mathematicians' example-based reasoning activities and their deductive reasoning activities. Several mathematics education researchers have accordingly examined various aspects of the relationship between example-based reasoning and deductive reasoning activities among both mathematicians and mathematics students (e.g., Antonini, 2006; Buchbinder & Zaslavsky, 2009; Ellis, et al., 2012; Iannone, Inglis, Mejia-Ramos, Simpson, & Weber, 2011; Lockwood, et al., 2012, 2013).

The case study presented in this paper builds directly on the findings by Lockwood et al. (2012) in which 219 mathematicians responded to an open ended prompt on a survey: *If you sometimes use examples when exploring a new mathematical conjecture, how do you choose the specific examples you select in order to test or explore the conjecture? What explicit strategies or example characteristics, if any, do you use or consider?* Results of the responses produced a framework for types, uses, and strategies of examples (Lockwood et al., 2012), but here we emphasize one particular use of examples that arose in the mathematicians' responses: proof insight. Fourteen of the mathematicians' responses (5.6%) indicated that they use examples in order to gain insight about how to develop a proof for the conjecture. In addition, in the interview study from which this case study is drawn, there were 23 out of 228 total instances (10.1%) in which mathematicians similarly made statements about examples serving an important role in proving conjectures. While there is evidence that mathematicians might use examples to gain insights into proofs, little is known about the precise mechanisms by which this may happen. We thus build upon such prior work on mathematicians and proving by emphasizing in particular the role of examples as a mathematician produces a proof.

Additionally, the conjecture discussed in this paper is adapted from Alcock & Inglis (2008), in which they discuss different ways in which doctoral students used examples in working with conjectures. Our findings build directly upon their work, as we seek to draw a more in-depth picture of precisely how a mathematician's choice and use of examples helped contribute to his successful proof production.

Methods

The case study presented in this paper is from an interview conducted with a mathematician, Dr. Felton (a pseudonym), as he explored and attempted to prove three mathematical conjectures (due to space, only Conjecture 2 is provided, see Figure 1). Dr. Felton, currently an associate professor in a university mathematics department, received his PhD in mathematics with an emphasis in mathematics education; his area of mathematical expertise is algebra. After working on each conjecture, Dr. Felton was asked clarifying questions about his work. While he was not

given unlimited time (he had approximately 15-20 minutes to explore each conjecture), Dr. Felton was able to sketch of a proof of Conjecture 2 (parts a and b) and Conjecture 3. His work on Conjecture 2 (a task adapted from Alcock & Inglis (2008)) is the subject of this paper.

Conjecture 2
All the numbers below should be assumed to be positive integers.
Definition. An abundant number is an integer n whose divisors add up to more than $2n$.
Definition. A perfect number is an integer n whose divisors add up to exactly $2n$.
Definition. A deficient number is an integer n whose divisors add up to less than $2n$.

Conjecture 2a. A number is abundant if and only if it is a multiple of 6.
Conjecture 2b. If n is deficient, then every divisor of n is deficient.

Figure 1: Conjecture 2a and 2b

All of the interview problems were chosen because they were a) accessible to the mathematicians (regardless of their area of expertise) but not so clearly obvious that they could be proven immediately, and b) accessible to the interviewer, allowing her to follow the mathematicians' work as well as to ask meaningful follow-up questions. While the choice of conjectures did not exactly simulate a mathematician's personal research, the conjectures enabled us to observe what a mathematician might do as he actually explores and attempts to prove conjectures.

The interview was transcribed, and, having identified Dr. Felton's work on Conjecture 2 as involving an illustrative instance of examples leading to proof development, a member of the research team carefully analyzed Dr. Felton's work on Conjecture 2 in particular. The process involved repeated viewings of his work on this conjecture, identifying and characterizing precise ways in which Dr. Felton used specific examples in develop a proof. Findings were discussed and refined during meetings with other research team members.

Results and Discussion

In this section we present a detailed account of Dr. Felton's work on Conjecture 2, including some analytic discussion; in the subsequent Conclusion section we synthesize the results and highlight salient aspects of his proving process. This section is broken into three subsections: *initial exploration*, *targeted exploration*, and *sketching the proof*.

Initial Exploration

Dr. Felton first solved Conjecture 2a, identifying 6 as a counterexample. He stated that he was not familiar with perfect numbers but had recently thought about 6's property that its proper factors sum to itself, which he learned was the definition of perfect. His choice of counterexample here was relevant, as 6 would be a key aspect of his exploration and proof of Conjecture 2b.

After he initially read Conjecture 2b, his reaction was to think it might be true, because "it's hard for me to imagine a counterexample." Having made this assertion, he began a symbolic proof (in line with what Weber and Alcock (2004) call *syntactic* proof production), writing down expressions such as $a*d=b$ and denoting a as having factors $f1, f2, f3$. However, he did not successfully generate a proof and decided that he would try some examples, saying, "This is going to be an interesting one. I feel like I might want to play with a few examples."

The interviewer asked Dr. Felton both why he had initially attempted a symbolic proof, and why he had shifted from that proof attempt to working with specific examples. He explained these decisions in the excerpt below.

Dr. Felton: Well, probably at first I was, well, partly I started with the algebra because…I was already feeling like it was probably true. And I was hoping maybe I'd get lucky and something would jump out at me, the strategy for proving it…And then the real reason why I went after it with examples, not so much that I thought these would be counterexamples, as I thought they would be good test cases, and they'd maybe give me a feel for how, more information as to maybe why this is true.

Since Dr. Felton suspected the conjecture was true, he had hoped that a strategy for a proof would emerge from the algebraic manipulation. Also, he chose specific examples as test cases, hoping they would inform *why* the conjecture might be true. We address what he meant by "test cases" below.

In the following excerpts we follow Dr. Felton's work as he studied a specific example, 12 (6*2=12). What is noteworthy about this work is the care with which he chose this and subsequent examples, and also how he attended to particular mathematical features of the examples. Specifically, he noted that choosing an example that had a perfect factor (such as 6) was judicious because the factor was barely not deficient.

Dr. Felton: I'm curious about 12, now. So, let's see, 2 times 6 equals 12. We know 6 is perfect, which doesn't necessarily make it deficient. It's not deficient…so actually it's a good choice for a potential counterexample, because it's not deficient, but it's not far from being deficient… So, if something's going to work, my, I guess a good way to do it would be to use a perfect factor.

Interviewer: Okay. As opposed to an abundant one?

Dr. Felton: As opposed to an abundant one…'cause then you're going to get tons of stuff which is going to make it harder for you to not make up the difference with the extra.

He would later go on to say that by choosing an example with a factor that was perfect (as opposed to abundant), he was targeting a "test case," or a "boundary case." He described the perfect number as being a boundary situation, "I mean, it's definitely the boundary case here 'cause you have two definitions and perfect is in the middle of the two of them." He later said, "I mean, my emphasis, my focus will probably always be on a boundary case in that kind of a situation… Like what's that critical point when you switch from being one to the other." These comments exemplify Dr. Felton's strategic choice of examples in helping him understand the conjecture. Indeed, Dr. Felton situated the examples he chose within the larger picture of what he was trying to accomplish. We have evidence that by choosing 12 (which has a perfect factor) he was not actually trying to locate a counterexample, but rather to gain insight into the conjecture: "Yeah, I'm mostly, just to kind of play with it. Like, I don't, I really have no belief that there could be a counterexample. But I'm pretty sure this one is true." He acknowledged that he likely would not find a counterexample, and he recognized that while he might not break the conjecture, he could potentially gain insight into the situation, and possibly formulate a proof, by exploring the boundary case 6*2=12.

In working through this example, Dr. Felton wrote out the factors of 12. Below, we see that he made an important observation about this example, noting a specific property, namely that his factor of choice, 6, was exactly half of 12.

Dr. Felton: So 12 has 1, 2, 3, 4, 6. And it also includes 12 in this calculation. Okay, so, so we're looking at this going 1, 2, 3, 6. Um, those guys are giving me the 12, oh, wait a minute. Hold your horses, here. Okay, is that just 'cause it's a half, though?…You're already getting half way there with that one [the 6]. This isn't going to be very helpful when we do, there's

no way this is going to be deficient… because there's already a 12 in that one. This, this conjecture is feeling quite true.

Dr. Felton suspected that the conjecture was true, and his work with the example 12 seemed to have confirmed that, but he became aware of this special property that he identified, and he was cognizant that he perhaps had come upon a special case. We interpret that he noted that for his example e, if a factor f is perfect and is half of e, then because it is perfect all of its factors will sum to f. But f is also already somewhere in the list of e's factors, and this guarantees that the factors of e will already sum to at least twice f (which is e), making e not deficient. This realization that he had chosen an example with a perfect factor that was exactly half of the number led him to another strategic example choice, and he noted "I'm just going to kind of play with one more, see if it's a generalizable phenomenon."

Targeted Exploration

We call this section *targeted exploration*, as his observation about 6*2=12 resulted in intentional examples choices that followed a particular line of inquiry. Based on properties he identified about his initial example described above, he chose 18 (6*3=18) and again paid attention to the factor that was half of his example, in this case 9. Interestingly, in the excerpt below, Dr. Felton made a technical error in his reasoning, because 9 is actually deficient (its proper factors sum to 4, which is less than 9). However, his observation in the excerpt is still insightful, and it played an important role in his subsequent example choice. The point to glean from the following exchange is his observation that if half a number is already not deficient, then the original number will not be deficient.

Dr. Felton: Because as long, it's, if it's [the factor that is half of the original number] not deficient, that guarantees that your number is not deficient, so it's like a contrapositive thing going on. Right, so nine is not deficient, it's going to have, the sum of its factors is going to give you two times nine.

Interviewer: Oh, I see. Yeah. So you're saying it's an even number and half that number is already not deficient…

Dr. Felton: Right. Then the original won't be deficient.

In spite of his error, this was a key observation, and it led him to choose an example with a particular property. The excerpt below shows that his work with 12 and 18 made him want to choose an example, "something like 6 times 11. I want to have a big, like, not much stuff between 6 and the whole number." We see, then, that his initial choice was based on 6 being perfect, and he chose 6*2=12 as a test, or boundary, case. Then, in examining that example he noticed the special property that arose because 6 was half of 12. This led him intentionally to choose an example in which 6 was not half of the original number, and he selected 6*3=18 to see if his observation is a "generalizable phenomenon." He similarly scrutinized this example, and the way in which 9 interacted with 18 made him move on to select an example that did not have "much stuff between 6 and the whole number." Based on this criterion, he chose 6*11=66, and this ended up being the example that would provide the key insight for the proof.

Having justified his next selection of 6*11=66, Dr. Felton then spent time investigating this chosen example, first writing out factors of 6*11=66. Then, as he studied the factors of 66 (see Figure 2), he made the following observation. As his last sentence suggests, his observation about the "duplication of the perfectness of 6" was enough to make him think that he could come up with a proof.

Dr. Felton: It's almost like you get, like a duplication of the perfect-ness of 6 that shows up in this piece here.

Interviewer: Okay, how so?
Dr. Felton: So, so, like this 1, 2, 3 adds up to 6…11, 22, 33 actually adds up to 66. So I'm feeling like I probably ought to be able to prove that this is a true statement.

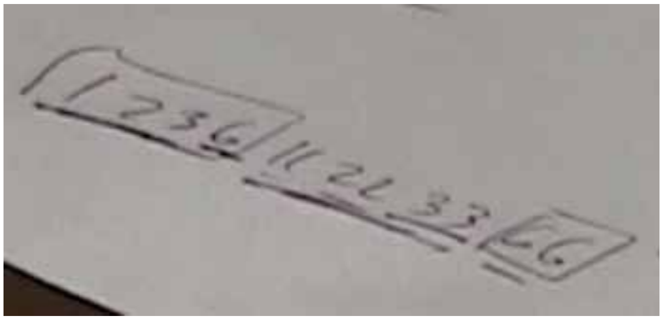

Figure 2: The Perfect-ness of 6 in the Factors of 66

Sketching the Proof

As alluded to previously, Dr. Felton was trying to prove the contrapositive of Conjecture 2b. For the sake of space we briefly summarize his proof, but Figure 3 shows him writing out the sketch of proof and simultaneously referring back specifically to his example in doing so. (In his notation, *b* is the number chosen as the example (*b*=66), *a* is the factor of interest (*a*=6), and *d* is another divisor of *b* (*d*=11)). He was able to prove the contrapositive, arguing that that if a factor of *b*, *a*, is not deficient, then it has factors *f1* through *fk* whose sum is greater than *a.* Then *d*f1* through *d*fk* must also be factors of *b* that are distinct from those factors of *a* (and since *f1* through *fk* are strictly less than *a, d*f1* through *d*fk* must be distinct from *b*). He noted that the sum of *d*f1* through *d*fk* must be greater than or equal to *d*a*, which is itself already a copy of *b*. The sum of *b*'s factors, then, includes *d*f1* through *d*fk,* which is greater or equal to *d*a*, and *b* itself. This is greater than or equal to two copies of *b*, and thus by the definition of deficient, *b* itself cannot be deficient.

Figure 3: Referring to the Example in Writing the Proof

What is most interesting to us is not that he proved the conjecture, but rather the precise role that his example 6*11=66 played in his development of this proof. In reflecting on his proof, he made several statements that highlighted the importance of the example. Specifically, the nature of the multiplication by 11 allowed him to see that certain factors (the multiples of 6) would show up in the complete list of factors. While this is a property that he asserted, "is clearly always going to work out," he acknowledged that the nature of the number 11 made that particularly salient for him. This focus on structure is seen in the following excerpt.

Interviewer: You said something about, maybe, start, being able to start a proof based on that observation you found in that six times eleven…

Dr. Felton: Right, which is kind of what I was thinking of was that the perfect-ness of the, um, 6 is basically copied, replicated by these multiples. Each multiple of the factor of 6. So I've got my 1, 2, 3, 6 here. Right now the 1, 2, 3, adds up to 6. And then multiply each of those by 1, those are also in my list of factors, and I add those up, I get 66. Which, kind of is clearly always going work out…But then when I wrote it down it was actually quite helpful because, I mean, I was also benefited by the choice of 11… Because you multiply by 11, it looks very much like the number you started with before you multiplied by 11… And so, it was much more transparent that the structure on this 11, 22, 33, 66 mirrored the 1, 2, 3, 6.

Conclusion and Implications

In this section we highlight three aspects of Dr. Felton's use of examples as he developed his proof of Conjecture 2b, and we suggest that these specify particular ways in which examples can be leveraged in the proving process. First, Dr. Felton demonstrated that he chose examples in terms of the larger task at hand. He explored a boundary case as a potential counterexample not to attempt to disprove the conjecture, but rather to gain insight into the situation. This activity suggests that he had an understanding of the logical structure of the conjecture, and by looking at an example that would not satisfy the conclusion he was setting himself up for a proof of the contrapositive.

Second, Dr. Felton drew upon particular mathematical properties of his examples, and these led him to strategic subsequent example choices. As described above, the sequence of examples he chose were based on careful mathematical analyses of each example. This activity suggests that Dr. Felton did not choose his examples thoughtlessly, nor did he use his examples merely to check whether the conjecture might be true. Rather he intentionally chose examples, carefully examined their mathematical properties, and used mathematical insight to understand the situation and inform ensuing example selection.

Third, Dr. Felton leveraged the structure of one insightful example in formulating a proof of the conjecture. The nature of the number 11, and the way in which it multiplies, allowed him to recognize in the particular example a key insight about the proof – namely that for all the factors $f1$ through fk of a, $d*f1$ through $d*fk$ would also be factors of b (for $a*b = b$). While he granted that the choice of 11 was fortuitous, he capitalized on this important structure and was able to translate it into the more general argument. As we see in Figure 3 above, he specifically aligned his writing of the proof with the structure of that particular example. This is an instance in which an informed example choice directly affected proof development.

We have previously argued for the value of strategic example choice and progressions of examples, and we have made the case that example structure can play a part in deductive reasoning (Ellis et al., 2012). Additionally, mathematicians have indicated that examples can shed light on proof or lead to proof insight (Lockwood, et al., 2012), but there is not much information on how this occurs. Here, however, we have evidence for how such example-related activity led to a proof in a precise way. Dr. Felton made informed decisions in initial example choice, and he targeted examples with certain mathematical properties. He carefully studied the examples and drew out salient insights from each of them. We do not claim that this is how every conjecture is proved, nor is it how Dr. Felton would even prove every conjecture, nor is it necessarily how people always *ought* to prove conjectures. However, this case study contributes to our understanding of the conceptual landscape of the interplay between examples and proof

production, pointing to some mechanisms by which example-related activity might lead to proof. Dr. Felton's work also offers some potential pedagogical insight. Students might benefit from modeling his careful selection of a progressive sequence of examples, or from leveraging the structure of a specific example, as he did. Additionally, Dr. Felton exhibited particular attitudes toward examples that could benefit students – he was willing to explore with boundary cases, was cautious of overreliance on a special case, and always seemed to keep the larger proving process in mind. Such facility with and attitudes toward examples might provide starting points for meaningful pedagogical interventions that positively frame examples in the context of proof.

VISUALLY GROUPING OPERANDS: PERCEPTUAL FACTORS INFLUENCE ARITHMETIC PERFORMANCE

Matthew J. Jiang	Jennifer L. Cooper	Martha W. Alibali

Perceptual characteristics of mathematical equations may influence solvers' problem solving. For example, in a study of equations involving addition and multiplication, Landy and Goldstone (2010) showed that participants tended to perform narrowly spaced operations first, suggesting that spacing affects how symbols are grouped for problem solving. Building on this past work, we examined whether perceptual factors affect participants' interpretations of the minus sign. In an experiment with undergraduates, we manipulated the spacing of the operands and the position of the minus sign relative to its neighboring operands. Both the operands' spacing and the position of the minus sign affected performance. These results hold implications for the processing of symbolic representations and for mathematics education.

Keywords: Number Concepts and Operations, Problem Solving

In the abstract symbol system of mathematics, individual numerical and operational symbols are combined into more complex mathematical expressions. These combinations take place in a two-dimensional representational system, in which spatial features may be relevant or irrelevant to formal mathematics. For example, a relevant spatial feature would be the ordering of the digits and operators in a given mathematical equation—because mathematically correct solutions to multi-operation arithmetic problems are reached by following mathematical rules, such as the order of operations. Similarly, the size and spatial location of a superscripted digit to indicate an exponent differentiates its mathematical meaning from the digit used as the base. In contrast to these examples, there is no difference in the formal mathematics of an expression when the horizontal spacing of the symbols is varied; correct application of the order of operations rule should yield the correct answer, regardless of how the equation is horizontally spaced.

However, some recent evidence suggests that, despite its formal irrelevance to mathematical meaning, horizontal spacing affects problem solvers' solutions. Landy and Goldstone (2007a) found that the amount of space surrounding operands influenced participants' judgments of the equality of two mathematical expressions. For example, undergraduate participants were more likely to agree with the statement "Is a + b * c + d = b + a * c + d necessarily true?" when the multiplication operations were more widely spaced than the addition operations (i.e., a + b   *   c + d = b + a   *   d + c), compared to when they were equally spaced. Participants made more errors when spacing was inconsistent with the mathematically correct order of operations (as discussed in Landy & Goldstone, 2007b).

Effects of spacing also are present when people construct mathematical expressions. Evidence from problem transcriptions show that participants implicitly follow spatial patterns when converting equations from word form (e.g., three plus five times two) to number form (e.g., 3 + 5 x 2). Participants spaced multiplication signs more narrowly than plus signs, signifying the precedence of multiplication (Landy & Goldstone, 2007b).

Effects of spacing on performance are also apparent in the time it takes for participants to solve problems (Landy & Goldstone, 2010). Participants solved equation structures of the form

"a + b x c" or "a x b + c" faster and more accurately when the multiplication operation was spaced more narrowly than the addition operation (e.g., a + bxc or axb + c, as compared to a+b x c or a x b+c). Participants displayed higher accuracy on problems with spacing that was consistent with the order of operations rules, and they also processed those equations more quickly.

These findings indicate that, irrespective of its formal irrelevance, the horizontal spacing and proximity of operands and operations can influence people's interpretation and understanding of mathematical expressions. Moreover, it appears that the relationship between horizontal spacing and arithmetic performance is bidirectional. People's knowledge about the order of operations can influence the spacing they use when writing expressions, and spacing can affect the order in which they perform operations when evaluating or solving problems. Furthermore, these findings may have important implications for educational practice. Instructors may be able to use these perceptual features to their advantage in classroom instruction.

In light of these previous findings, the minus sign (i.e., "–") is a particularly interesting case, because it is used not only to represent subtraction, but also to invert the sign of a number. Consequently, the minus sign is sometimes treated differently from other operation symbols; for example, it is "carried" with the associated operands in algebraic manipulations. This can present challenges for students learning algebra (Cangelosi, Madrid, Cooper, Olson, & Hartter, 2013; Demby, 1997; Vlassis, 2004). In addition, as a mathematical operation, subtraction is more difficult than addition (e.g., Das, LeFevre, & Penner-Wilger, 2010). In this study, we investigate whether formally irrelevant perceptual features can influence how the minus sign is interpreted. If perceptual features influence subtraction, as they do addition and multiplication, our research findings may be important for understanding students' difficulties at the transition between arithmetic and algebra.

In the present research, we investigated the effects of perceptual grouping of operands on participants' interpretations of the minus sign. Participants were presented with multi-operation expressions that involved subtraction. The equations were in the format of "a – b + c x d". We tested whether undergraduates' arithmetic accuracy would be enhanced by supportive yet formally irrelevant perceptual cues consistent with order of operations rules or hindered by misleading, formally irrelevant perceptual cues inconsistent with orders of operations rules.

Building on Landy and Goldstone's previous work (2007a, 2007b, 2010), we varied two aspects of spacing: the closeness of *operand spacing* and the lateral *minus sign position*. Before presenting our experimental method, we describe each of these variations and how they might affect performance. In both cases, the variations we employed were subtle, consisting of only one or two spaces in a normal-sized font.

First, we varied the *operand spacing*, specifically for the operators that followed the minus sign. To do so, we removed the spaces between operands and operations for the last three terms, similar to Landy and Goldstone's (2007a) manipulation. The closer proximity of the symbols may lead solvers to perceptually group these terms, as suggested by the Gestalt principles of visual perception (e.g., Werthmeimer, 1923/1938). Evidence from past research (e.g., Landy & Goldstone, 2010) suggests that visually grouping these symbols should give them precedence in problem solving steps. That is, the narrower spacing of these symbols (e.g., 25 – 3+2x5) could create a perceptual group which might lead participants to construe "3+2x5" as the subtrahend, and mistakenly apply the subtraction operation to this entire quantity. This would lead to the error described in Table 1, which we term a "target error". In erring this way, participants incorrectly evaluate the scope of the minus sign, due to the perceptual grouping.

Second, we varied the *minus sign position,* again based on the Gestalt principle of proximity (Wertheimer, 1923/1938). We horizontally shifted the minus sign (see Table 2 for a visual display) to create different perceptual groups. For instance, in the equation "25 – 3 + 2 x 5 = ____", if the minus sign were shifted slightly to the left, (25 – 3 + 2 x 5 = ____), solvers should be more likely to group the remaining symbols "3 + 2 x 5". This, too, may lead participants to produce the target error, because the minus sign may be applied to the entire quantity of "3 + 2 x 5" because of the perceived group. In contrast, if the minus sign were shifted to the right, solvers should be more likely to group the operator with the subsequent subtrahend of 3. Thus, manipulating the lateral position of the minus sign has the potential to affect the quantity participants treat as the subtrahend.

Table 1: Incorrect Solution Strategy Based on Incorrect Perceptual Grouping

Problem	25 – 3 + 2 x 5 = ____	correct answer = 32
Step 1	multiply: 25 – 3 + 10 = ____	correctly following order of operations
Step 2	add: 25 – 13 = ____	Demonstration of a "target error" with incorrect order of operations, potentially based on perceptual grouping of all symbols to the right of the minus sign
Step 3	subtract: = 12	

Although we could have tested many other perceptual features, we chose these two manipulations because of their implications for how the subtrahend is determined. The *minus sign position* manipulation directly alters the proximity of the minus sign to other elements in the equation; this manipulation relies on the proximity of the operator to its operands to generate supportive or misleading perceptual groups. The *operand spacing* manipulation more subtly affects the how the minus sign is drawn into the subtraction operation; the closeness of the latter terms may again prompt a perceptual grouping that influences a solver's interpretation of the scope of the minus sign by affecting the perceptual group that is treated as a subtrahend.

In sum, we hypothesized that perceptual cues inconsistent with the order of operations rules would encourage solvers to incorrectly group operations together and lead to errors in problem solving. Both the mathematically irrelevant spatial features of minus sign position and spacing of the remaining operands could potentially affect how the scope of the minus sign is interpreted. Despite their formal irrelevance, we expected these manipulations to affect participants' solutions to arithmetic problems involving the minus sign.

Methods

Participants

Undergraduate students (N = 92) in introductory psychology at a large Midwestern university participated in exchange for extra credit. Sixteen additional participants were excluded due to a photocopying malfunction leading to faulty stimuli.

Design and Materials

Participants solved arithmetic problems with manipulated perceptual features. In the target problems, subtraction was the first operation presented the equation, followed by addition, and finally multiplication (e.g., 25 – 3 + 2 x 5).

A 2 (*operand spacing*: evenly spaced or closely spaced) x 3 (*minus sign position*: left shift, no shift, or right shift) between-subjects design was used, yielding a total of 6 conditions. Table 2 displays the outcomes of these manipulations. In the evenly spaced problems with no shift, there were two spaces between each operand and the adjacent operator and two spaces around the equal sign. The left-shift condition was created by reducing the space between the first operand and the minus sign by one space and adding a space between the minus sign and the subsequent operand. The opposite was done for a right shift. For the closely-spaced condition , all the spaces after the second operand were removed, which resulted in no spaces between the last two operators and their three surrounding operands, as seen in the first row of Table 2.

Table 2: Example Target Problem with Shift and Grouping Manipulations

	Minus Sign Position		
Operand Spacing	**Left Shift**	**No Shift**	**Right Shift**
Evenly Spaced	25 – 3 + 2 x 5 = ____	25 – 3 + 2 x 5 = ____	25 –3 + 2 x 5 = ____
Closely Spaced	25 – 3+2x5 = ____	25 – 3+2x5 = ____	25 –3+2x5 = ____

Participants received ten target problems and eight control problems of the form "a + b – c x d". The control problems did not afford the target error that the target problems did. The operands in the equations were randomly generated, with the constraint that both the operands and solutions were non-zero positive integers. The problems in each condition were presented in a fixed order and the same operands were used for any given problem across conditions.

On each of the 8.5" x 5.5" (wide) pages of the packet, there were two math problems, separated by a fill-in-the-blank vocabulary question (as seen in standardized tests such as the SAT) as a filler. Size-12 Calibri font was used for all the questions, and the questions were numbered at the left margin. The packets were constructed such that the pages with the target math problems alternated with pages with the control math questions.

Procedure

Participants were tested in groups of up to five students at a time; each completed his or her packet of problems individually. Each participant was given a question packet with the math problems and vocabulary filler questions. Participants had up to thirty minutes to complete the question packet. Once participants finished the problem set, they were asked to provide information regarding their math and reading backgrounds and other relevant demographic information such as year in school and major.

Results

We scored whether each solution on each target problem reflected the target error or not, that is, whether the participant used a mathematically incorrect but perceptually-based group to solve the problem. Thus, careless arithmetic errors (e.g., 3 + 3 = 9) and errors that involved solving from left to right without consideration of order of operations (e.g., 25 – 10 + 3 x 2 = 36), while mathematically incorrect, were coded as No Target Error.

We analyzed the existence of target errors with a mixed effects logistic regression model using the glmmadmb package (Skaug, Fournier, & Nielsen, 2012) in R. Our two factors, minus

sign position and operand spacing, were treated as fixed effects that were allowed to interact, and participant was a random effect.

Figure 2 presents the mean proportion of trials with target errors in each condition. When the operations that followed the minus sign were closely spaced, participants in the left shift condition produced significantly more target errors than participants in the right shift condition, $p = .028$. The left-shift condition did not yield significantly more target errors than the no-shift condition, although the results trend in this direction. Additionally, within the closely-spaced condition, participants in the no-shift condition produced marginally more target errors than participants in the right-shift condition, $p = .059$. However, in the evenly-spaced condition, there was no difference in the proportion of target errors among the left-shift, no-shift, or right-shift conditions.

Focusing on the effects of the position manipulation, when the minus sign was shifted to the left, participants in the closely-spaced condition produced more target errors than participants in the evenly-spaced condition, $p = .026$. Close spacing also led to significantly more target errors than equal spacing when there was no shift, $p = .038$. However, when the equal sign was shifted right, there was no difference between the closely- and evenly-spaced conditions, $p > .05$.

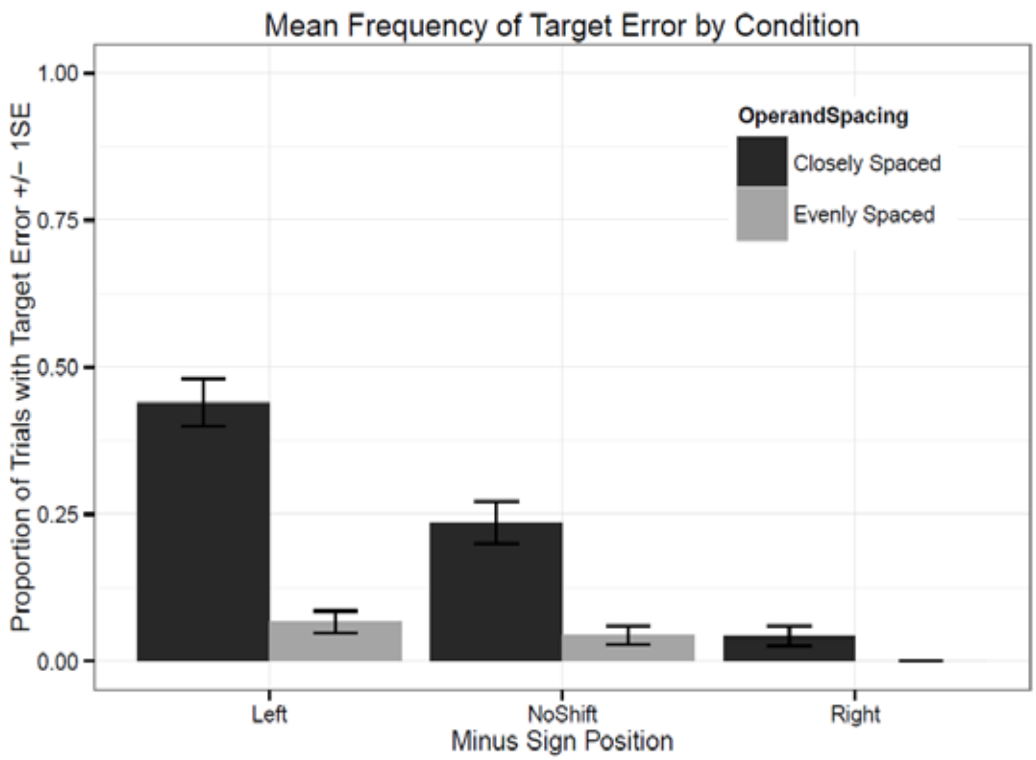

Figure 1: Proportion of Trials with Target Errors by Condition

In summary, target errors were most frequent when the minus sign was shifted left and the operations that followed the minus sign were closely spaced. Closely-spaced symbols were associated with more target errors than evenly-spaced symbols, for both the left shift and no shift conditions. Overall, the proportion of target errors within the closely-spaced condition was affected by the position of the minus sign. On the other hand, target errors were very low when

the operands were evenly spaced, and the proportion of target errors within the evenly-spaced conditions was not affected by the position of the minus sign.

Discussion

This study investigated whether spatial properties of equations would encourage participants to misevaluate the scope of the minus sign. We found that shifting the minus sign to the left and closely spacing the operations that followed the subtraction operation increased the frequency of the target error. This means that participants used the perceptually-based groupings instead of the mathematically-correct grouping, as defined by order of operations rules. Thus, when the manipulations afforded perceptual groups, participants were more likely to perform the perceptually grouped operations first, despite the inconsistency with formal mathematics. The variations we implemented in the position of the minus sign and spacing of the operations did not alter the inherent meaning of the equations. However, the participants had more difficulty accurately processing equations with perceptual features that were inconsistent with the order of operation rules. These findings extend past research by Landy and Goldstone (2010), and they indicate that multiple ways of manipulating perceptual grouping can influence participants' interpretations of mathematical equations and guide their problem solving.

Equations with the final three operands spaced closely elicited more target errors, except when the minus sign was shifted right (e.g., 25   – 3+2x5 = ____). In the right-shift condition, participants seem to have incorporated the minus sign as part of the subtrahend, and this may have protected them from making the target error. This suggests that participants in the right-shift condition were either more likely to perform the multiplication and then go back to the beginning of the equation *or* to realize that the minus sign could be applied to the subsequent operand, making it negative. In contrast, participants in the left-shift and closely-spaced condition, in which the target error was most prevalent, tended to ignore the minus sign (perhaps because it was spatially more distant) and to incorrectly perform the subsequent operation without the minus sign "riding along" (i.e., to calculate "3 + 10" instead of "–3 + 10" in the intermediate step).

The increased frequency of target errors in the left shift condition compared to the right shift condition suggests that perceptual factors may influence whether solvers activate the notion of negative numbers. The proximity of the minus sign to the subsequent operands in the right shift condition may have allowed participants to "attach" the minus sign to the subsequent perceptual group (e.g., in Table 1, "–3+2x5"), so that they viewed the subsequent operand (i.e., 3) as a negative integer. The more distant minus sign in the left shift condition may not have afforded this connection. This possibility is compatible with evidence from Vlassis (2004) suggesting that at the transition from arithmetic to algebra, students expand their understanding from natural numbers to integers, which may incorporate the minus sign to indicate that an integer is negative. However, our findings suggest that, when there is conflicting perceptual information, undergraduates may not automatically activate the notion of subtraction as adding a negative number.

There are many potential directions for future research in this area. One valuable next step would be to conduct a detailed analysis of participants' problem-solving steps, in order to better understand the processes through which perceptual spacing affected performance on these equations. It is possible that participants in the closely-spaced condition were more likely to start their solution process at the end of the expression (i.e., focusing on the grouped operands first).

This would further bolster the claim that perceptually grouped operations are likely to be performed first.

A second important future direction would be to directly investigate the relative prevalence of spatial and semantic information in problem solving. Our results suggest that spatial information may be processed *before* evaluating the semantic values of symbols. We suggest this given the evidence that participants used the perceptual groups to determine the subtrahend, rather than using the scope of the minus sign as defined by the order of operation rules. However, further research that directly investigates the integration of spatial and semantic information is needed.

This work could also be extended by investigating different types of problems, working with younger students who have less expertise at these operations, and considering the effects of math ability and attitudes on susceptibility to the making the target error. More generally, a deeper understanding of the role of the spatial factors is needed for a complete account of students' acquisition of computational and algebraic skills.

Finally, we believe that these data have important implications for educational practices. Perceptual features of mathematical expressions are a relatively little-studied area in mathematics education. However, perceptual features do affect performance, as we have shown here (see also Landy & Goldstone, 2007a, 2010). It could be beneficial to leverage the effects of spatial features on mathematical processing in instructional contexts. For example, spatial manipulations could be used to support students' learning of the order of operations rules, and spatial support could later be faded as students gain proficiency. Similarly, spatial cues based on proximity or other perceptual features (see Wertheimer, 1923/1938) could be implemented to reduce students' misinterpretations of the scope of the minus sign. Although the research here focused on proximity cues that afforded perceptual groups in arithmetic equations, mathematics in general uses a symbol system that incorporates spatial features in its representation. Overall, our findings suggest the need for a deeper consideration of the spatial characteristics of symbolic expressions used in mathematics instruction.

EFFECTIVE BUT UNDERUSED STRATEGIES FOR PROOF COMPREHENSION

Keith Weber
Rutgers University
keith.weber@gse.rutgers.edu

Juan Pablo Mejia-Ramos
Rutgers University
pablo.mejia@gse.rutgers.edu

We present five strategies that mathematics majors can use to improve their proof comprehension. We argue these strategies are effective by presenting qualitative excerpts illustrating the ways in which the employment of these strategies helped four undergraduate students understand the proofs they were reading. Furthermore, we present results of a survey in which the majority of 83 mathematicians indicated they would like students to use these proof reading strategies. Finally, we argue that these strategies are underused by presenting results from another part of the survey, in which the majority of 175 mathematics majors claimed not to employ these strategies.

Keywords: Reasoning and Proof, Advanced Mathematical Thinking, Post-Secondary Education

Introduction

In lamenting the quality of instruction in university mathematics courses, Davis and Hersh (1981) contended that “a typical lecture in advanced mathematics… consists entirely of definition, theorem, proof, definition, theorem, proof, in solemn and unrelieved concatenation” (p. 151). While such a description probably exaggerates the frequency with which proofs are presented in mathematics lectures, it is the case that much of the teaching in advanced mathematics courses consists of students observing the proofs that their professors present to them (e.g., Weber, 2004; Fukawa-Connelly, 2012; Mills, 2011).

To date, research in undergraduate mathematics education on proof reading generally falls into one of two categories. Some researchers have sought to examine the types of arguments that convince mathematics majors of the truth or falsity of mathematical statements. These researchers typically present students with arguments based on different types of evidence (e.g., empirical evidence, perceptual evidence) and ask students to evaluate the persuasiveness of these arguments (e.g., do you find this argument personally convincing?). The researchers use students’ evaluations as a lens to determine their proof schemes (e.g., Harel & Sowder, 1998; Segal, 2000). In a second category of research, researchers present mathematics majors with purported proofs and ask them to determine if the presented arguments are mathematically valid (e.g., Inglis & Alcock, 2012; Selden & Selden, 2003). This research reveals students’ difficulty with validation tasks as well as deficiencies in the processes they use to validate proofs.

In this paper, we introduce a third way to investigate mathematics majors’ proof reading by asking: what strategies can undergraduate students use to better comprehend proofs? The common pedagogical practice of presenting proofs to mathematics majors is based on the assumption that students can learn mathematics from reading them. Both mathematicians and mathematics educators question whether this assumption is true (e.g., Conradie & Firth, 2000; Cowen, 1991; Rowland, 2001). If mathematics majors do not gain understanding from the proofs that they read, it is natural to ask what strategies they can use to improve their comprehension. The purpose of this paper is to address this issue.

Theoretical Perspective

Our theoretical perspective builds upon answers to two related questions found in the literature: why do we present proofs to mathematics majors, and what does it mean for students to understand a proof? Central to the question of how mathematics majors should read proofs is why they are asked to read these proofs in the first place. Mathematicians read proofs published in journals for a variety of reasons, including understanding why theorems are true (de Villiers, 1990; Hanna, 1990) and finding techniques that would be useful for them to prove other theorems in their own research (e.g., Rav, 1999; Weber & Mejia-Ramos, 2011). Many mathematics educators argue that proof should play a similar role in mathematics classrooms. Proofs that merely convince students that a theorem is true are thought to have little pedagogical value (Hanna, 1990; Hersh, 1993), especially as many students are convinced a theorem is true if their teacher or textbook tells them that this is so (Harel & Sowder, 1998). Pedagogical proofs should also provide students with insights such as explanations of *why* the proven result holds true (Hanna, 1990; Hersh, 1993) and other related goals. Although secondary teachers do not appreciate these broader functions of proof (Knuth, 2002), interviews with mathematicians reveal that they present proofs to students for these purposes (Yopp, 2011; Weber, 2012).

Mejia-Ramos et al (2012) put forth a model delineating what it would mean for a student to understand a proof in advanced mathematics. In this model, a proof can be understood either locally as a series of individual deductions, or holistically based upon the ideas or methods that motivate the proof in its entirety. At a local level, understanding a proof would be comprised of (a) knowing the meaning of the terms and statements within the proof, (b) being able to justify how new assertions in a proof followed from previous ones, and (c) understanding how the assumptions and conclusions related to the proof method being used. In this model, the holistic understanding of a proof consists of being able to: (a) provide a summary of the proof that emphasizes its high level goals, (b) apply the methods of the proof in other situations to prove new theorems, (c) break the proof into sub-proofs, and (d) apply the methods of the general proof to a specific example.

As a final note, the ways that proofs are conventionally presented in advanced mathematics mean several dimensions of the Mejia-Ramos et al's proof comprehension model are not transparent. For instance, proofs often contain gaps where the reader has to infer what principles are being used to deduce new statements from previous ones (Weber & Alcock, 2005). The linear deductive manner in which proofs are written often inhibits students from seeing the higher-level ideas of the proof, or how the proof could be broken into its main parts (Leron, 1983). Hence, understanding a proof involves much more than making a literal translation of each statement within the proof, and requires active construction on the part of the reader. In this paper, we describe strategies that mathematics majors can use to facilitate such construction.

Methods

Rationale of this Study

This study employs both qualitative and quantitative methods. First, in a qualitative study, four successful mathematics majors were observed thinking aloud while reading six mathematical proofs. These videotapes were analyzed to identify proof reading strategies that were used by these students to facilitate comprehension. Excerpts from these videotapes illustrate the ways in which these strategies were effective. After these strategies were identified, a quantitative survey study was designed to determine the extent to which: (a) mathematics majors claim to use these strategies, and (b) university mathematics professors desire that their students use these strategies. This survey data provided evidence that these strategies were

mathematically desirable (from the viewpoint of mathematicians), but were not used by many mathematics majors (by their own self-report).

Qualitative Study of Mathematics Students Reading Proofs

Participants. Four seniors who were mathematics majors and prospective teachers agreed to participate in this study. These participants were chosen due to their success in their content-based mathematics courses (suggesting they used productive proof reading strategies), and because we found them to be thoughtful and articulate.

Materials. Participants were asked to read six proofs. For the sake of brevity, they are not included in this report but can be found in Weber & Samkoff (2011). The proofs were chosen such that the mathematical content relied on calculus and basic number theory (so lack of content knowledge would not inhibit proof comprehension) and the proofs employed an interesting technique with which the participants would not have extensive experience. For each proof, we generated comprehension questions using Mejia-Ramos et al's (2012) proof comprehension model described above.

Procedure. Participants met in pairs with the first author for a task-based interview. The first pair of students was assigned the pseudonyms Kevin and Tim, and the second pair was assigned Caleb and Derek. Participants were asked to "think aloud" as they were videotaped reading the proofs. They were given an individual proof and asked to read the proof until they understood it. Once this understanding was attained, the researcher took the proof and asked them to complete proof assessment questions. The interviewer then repeated this process with a new proof. This continued until all six proofs were read. Both pairs of students answered nearly every question correctly (which was uncommon in our proof reading studies), indicating that the pairs of students read the proofs effectively.

Analysis. Since we were looking to identify new strategies, and given that the proof comprehension literature is limited, we used an open-coding scheme in the style of Strauss and Corbin (1990) to identify new strategies. In the first pass through the data, we identified the strategies that were of interest to us. In the second pass, we coded explicitly for each use of those strategies.

Quantitative Survey Study

Survey items. For each strategy that we identified in the qualitative study, we created two survey items. For the mathematics majors, we generated a two choice survey item. Choice A claimed that they frequently used the identified strategy when they read proofs, while Choice B indicated that they did not regularly use the strategy. The survey item asked participants to choose whether they agreed with Choice A, Choice B, or were neutral between the two using a five-point Likert scale. The survey item for the mathematicians was similar, except they were asked if they would prefer that their students used the strategies, not that they would use the strategies themselves. For example, one of the identified strategies consists of trying to prove the theorem before reading its proof. For the students, the two choices in the survey item were:

A. When reading a theorem, I usually try to think about how I would prove the theorem before reading its proof.

B. I do not usually try to prove a theorem before reading its proof. A reason for reading the proof is to see why the theorem is true.

For the mathematicians, the two choices were:

A. When reading a proof of a theorem, I would prefer if mathematics majors think about how they might prove the theorem themselves before reading the proof.

B. I would prefer that mathematics majors not try to prove a theorem themselves before

reading its proof. A reason for reading the proof is to see why the theorem is true.

Participants. The participants in this study were invited to take part in an Internet survey. The participants from this study were conducted from 50 large state universities in the United States. The mathematics department secretaries at these universities were sent an e-mail asking them to forward e-mails to their faculty and their students. Mathematicians were invited to participate in a survey about proof reading with a link to a website for participation. Mathematics majors were sent separate request to participate in a proof reading study with a link to a separate website. Upon reaching the website, participants were asked for demographic information. For mathematicians, one question included whether they had ever taught a proof-oriented course. For students, one question included whether they had ever completed a proof-oriented course. If participants answered no to these questions, their responses were not included for analysis. 175 mathematics majors and 83 mathematicians met this requirement and completed the survey. Because the data were completely anonymous, we do not know which secretaries sent the requests to their faculty or students nor what percentage of faculty or students agreed to participate.

Results

We describe the five strategies that we observed.

Strategy #1: Trying to prove a theorem before reading its proof

For each of the six proofs that Kevin and Tim read, they would first try to prove the theorem before reading its proof. For instance, Kevin and Tim were handed a proof of the claim "$4x^3 - x^4 + 2\sin x = 30$ has no solutions". Immediately after reading the claim, Kevin and Tim began analyzing why the claim was true:

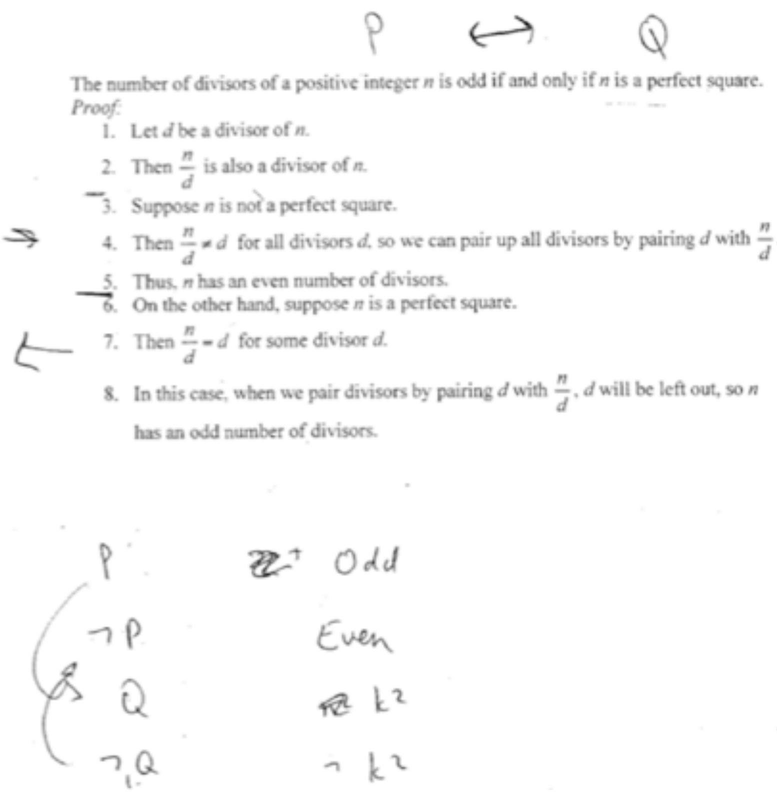
Tim: As x gets really big, it gets dominated by the negative x to the fourth term. And it's a parabola going down basically and it's going to get modulated a little bit.
Kevin: Right. And sine of x is…
Tim: Periodic.
Kevin: It is periodic so that wouldn't really affect it too much… out of the two functions, *f(x)* is the trumping one.
Tim: So in the long run, it's going…
Kevin: It's really *f(x)* that matters.
Tim: And the question is, does it reach 30.

It is important to note that Kevin and Tim were not only trying to understand the statement, they were also trying to understand why the statement was true. While they did not successfully produce a proof, their efforts at this stage appeared to help them comprehend the proof that they read. The proof itself had the same high-level ideas that Kevin and Tim highlighted: finding the bounds of $2\sin x$ and $4x^3 - x^4$. The details in the actual proof, such as using differentiation to find the critical points of $f(x)=4x^3 - x^4$, can be seen as supporting these high-level goals. In this sense, when reading the proof, Kevin and Tim did not view the proof as an aimless series of inferences and calculations, but rather saw the proof as satisfying two high level goals—finding the bounds of $2\sin x$ and $4x^3 - x^4$. Hence, trying to prove the theorem before reading the proof facilitated Tim and Kevin's ability to "structure" the proof (in the sense of Leron, 1983) and provide a summary of it. Other transcripts show how trying to write a proof helped Tim and Kevin understand the proof technique (e.g., proof by contraposition) being employed in the proofs that they read and identifying techniques that were novel to them in the proof that might be useful in other settings.

Using the survey item described in the previous section, we found that 88% of the survey mathematicians chose choice A, desiring students use this strategy, but only 31% of the mathematics majors chose choice A, suggesting most mathematics majors do not use the strategy.

Strategy #2: Comparing the assumptions and conclusions in the proof with the proof technique being used and Strategy #3: Breaking a longer proof into parts or sub-proofs

We illustrate both strategies by showing how Tim and Kevin read the proof presented in Figure 1:



P $\longleftrightarrow$ Q

The number of divisors of a positive integer *n* is odd if and only if *n* is a perfect square.

Proof:

1. Let *d* be a divisor of *n*.
2. Then $\frac{n}{d}$ is also a divisor of *n*.
3. Suppose *n* is not a perfect square.
4. Then $\frac{n}{d} \neq d$ for all divisors *d*, so we can pair up all divisors by pairing *d* with $\frac{n}{d}$.
5. Thus, *n* has an even number of divisors.
6. On the other hand, suppose *n* is a perfect square.
7. Then $\frac{n}{d} = d$ for some divisor *d*.
8. In this case, when we pair divisors by pairing *d* with $\frac{n}{d}$, *d* will be left out, so *n* has an odd number of divisors.

Figure 1: Tim and Kevin's Employment of Strategies 2 and 3

Kevin: From [lines] two to four, it's doing the proof by contradiction. Suppose *n* is not a perfect square. […]
Tim: Suppose *n* is not a perfect square. So you're saying, suppose not this?
Kevin: For which one?
Tim: So you're saying, suppose *n* is not perfect, right, and that's the opposite of the right side.
Kevin: Cause it's dichotomous. If it's not a perfect square, then it's even. So therefore if P implies Q, then not Q implies not P, right? Contrapositive.
Tim: So we're saying this is P [writes P above "the number of divisors of a positive integer n is odd], this is Q [writes Q over "n is a perfect square"].
Kevin: OK sure. So P is a positive integer, right? Positive integer?... Right?... Positive integer?
Tim: Is odd?
Kevin: Right. Sorry. P is odd, right? So then not P would be even. So Q would be a perfect square, k squared. And not Q would not be k^2 or whatever. So here, [referring to lines 3-5 of

Proof 5] it shows not Q implies not P.

Tim: And this part of the proof ends at 5 [Tim draws horizontal dashed between lines 2 and 3 and between lines 5 and 6 to partition the two parts of the proof]

Kevin: So it shows not Q implies not P and therefore P implies Q. So it's proving it forwards. [Tim rights a right arrow next to lines 3, 4, and 5]. It's the forwards way. [Reading line 6] On the other hand, suppose *n* is a perfect square. So now it's going to prove the backwards.

Selden and Selden (2003) and Weber (2010) found that students would often accept a proof of a conditional statement as valid in cases where the proof began by assuming the conclusion of the conditional statement and deduced the antecedent—i.e., the argument proved the converse of the statement. Both research teams took this as evidence that participants did not attend to the proof framework of the proofs that they were reading. The excerpt above illustrates that Kevin and Tim explicitly attend to the assumptions and conclusions of the proof to understand how a valid proof technique is being employed. The surveyed students were presented with these choices:

A. When I read a proof, I first consider is what is being assumed, what is being concluded, and what proof technique is being used.

B. When I read a proof, I first consider how each new statement can be derived from previous statements.

Only 33% of the mathematics majors preferred A, but 64% of the mathematicians preferred A for the analogous item (not presented here for the sake of brevity). In the transcript and figure above, we also see how Kevin and Tim broke the proof into two parts, lines 3 through 5, and lines 6 through 8. This was something that both pairs of students regularly did. In the survey, the mathematics majors were given the following two choices.

A. When I read a long proof, I try to break it into parts or sub-proofs.

B. When I read a long proof, I do not break it into parts but try to understand how each line follows from previous assertions.

Less than half (38%) of the mathematics majors chose A, but 88% of mathematicians chose A for the analogous items.

Strategy #4: Comparing the proof approach to the one's own approach

After reading the proof that "$4x^3 - x^4 + 2\sin x = 30$ has no solutions", Caleb and Derek noted that this is not how they would approach the problem. (The proof proceeded by showing $2\sin x \leq 2$ and $4x^3 - x^4 \leq 27$ for all real x).

Caleb: Definitely not the way I would have gone when I looked at it…

Derek: Not even close.

Caleb: Yeah, I would not have broken it down like that.

Derek: I would not have broken it down like that at all. How I would have solved this, I have no idea.

Caleb: Well when you start putting in trigonometric functions.

Derek: Yeah, that's when it starts getting a little hairy […] I probably would never have ever thought of this but from my background in calculus, it makes sense to me.

Caleb: Yeah, yeah. It's clever [laughs]

Derek: Yeah, it's clever. I never would have dreamed of coming up with something like this.

After reading all six proofs, Caleb and Derek were asked if comparing a proof strategy to one's own approach was something they regularly did. Both agreed that it was. When asked why they did this, Derek said: "it gives you new techniques to solve proofs like that".

The surveyed mathematics majors were given the following choices:

A. When I read a proof, I compare how the method used in the proof compares to the method I would use to prove the theorem.
B. When I read a proof, I try not to consider how I might approach the proof, but focus on what method was used in the actual proof.

Few mathematics majors selected Choice A (26%) but most mathematicians (87%) selected A when given the analogous choices.

Strategy #5: Using an example to understand a confusing inference

When both pairs of students were confused by a statement in number theory, they interpreted the general statement in terms of specific numbers in order to understand what the statement was asserting, and why it was true. For instance, one proof contained the line, "Let d be a divisor of n. Then n/d is also a divisor of n". Tim and Kevin were confused as to why the second claim should be true until Kevin said, "So, say 7 is a divisor of 21. So to get the other factor, it's 3". After this, the pair were satisfied that every product of a number contains two factors and if d was a factor, n/d would be the other factor. The surveyed students read the following choices:

A. When I read a new assertion in a proof, I sometimes check whether that assertion is true with a numerical example.
B. When I read a new assertion in a proof, I try to see how that new assertion is a logical consequence of previous statements. I do not check assertions with specific examples since you cannot prove by example.

A minority (43%) of mathematics majors chose A, but 77% of mathematicians chose A when given the analogous items, indicating most mathematicians would like students to use this strategy.

Discussion

This paper presents five strategies that mathematics majors can use to improve the comprehension of the proofs that they read. For each strategy, we illustrate how it can be useful with an episode of a pair of strong students reading proofs for comprehension. We then presented quantitative data indicating the majority of mathematicians would like their students to use these strategies, but less than half the students agree to regularly using these strategies. This suggests that if mathematics majors could be taught how to apply these strategies and were encouraged to use them, their proof comprehension performance might improve.

There are several caveats worth mentioning. There were only a small number of students (4) reading a small number of proofs (6) in the qualitative study. It is probable that interviewing other strong students or using other proofs would have evinced other strategies as well. Hence, we make no claims that the five strategies that we highlighted are exhaustive. Furthermore, the survey for students was self-report. It is possible that some mathematics majors might not have reported using these strategies, maybe because they were not aware that they did so. If so, explicitly naming and highlighting these strategies may help these students leverage them more effectively.

Finally, the link between identifying strategies and teaching students to use them is not straightforward. The use of these strategies likely relies on students' conceptual knowledge (that may or may not be adequate). Further, these strategies are descriptive and this description might not be detailed enough for students to use them effectively (see Schoenfeld, 1985). We are currently conducting teaching experiments, both to refine these strategies so they are useful to mathematics majors and to find environments and activities that foster the understanding, appreciation, and adoption of these strategies.

PROBLEM POSING AS REFORMULATION AND SENSE-MAKING WITHIN PROBLEM SOLVING

Victor V. Cifarelli
University of North Carolina at Charlotte
vvcifare@.uncc.edu

Volkan Sevim
Virginia Commonwealth University
vsevim@vcu.edu

The study examined problem posing as a form of sense-making that aids the solver's on-going development of goals and purposes throughout problem solving. Drawing from episodes of a Mathematics Education graduate student solving a number array task, our analysis explains: 1. How problem posing evolves from the solver's ongoing interpretations of the problematic situation; and 2. How these posed problems contribute to the solver's problem solving activity.

Keywords: Problem Solving, Learning Theory, Metacognition.

The Co-evolution of Problem Posing and Problem Solving

The study of mathematical problem posing has been an important area of investigation by researchers in mathematics education (Cai, Moyer, Wang, Hwang, Nie & Garber, 2012; English, 1997; Silver, 1994; Silver & Cai, 1996). Having students generate and develop their own problems from particular situations may help them become stronger problem solvers. Proponents of problem posing advocate for its inclusion in the mathematics curriculum for several reasons. These include the view that having students make up their own problems encourages self-reflection that may help students to better reflect on problem situations (NCTM, 2000; Schoenfeld, 1994). Reflection that involves planning potential solution strategies has been associated with effective problem solving in several studies of problem solving (Cifarelli & Cai, 2005). Hence, posing problems is viewed as an activity that may nurture mathematical thinking.

We believe that problem posing occurs throughout problem solving and that solvers use results to monitor the usefulness of current goals, revising or reorganizing their goals and purposes as needed to solve the problem. Problem posing is then a series of transformations of the original problem, with each successive problem posed indicating both progress towards a solution as well as possibilities for action to further expand the scope of the original problem.

Related Research

The exemplary research on problem posing comes from English (English, 1997) and Silver and his colleagues (Silver, 1994; Silver & Cai, 1996). While these studies have added to our knowledge of problem posing, the research is less certain about the roles played by problem posing in problem solving situations. How do the solver's initial problem formulations impact his or her solution activity?

Conversely, how do the student's reflections on carried-out solution activity help him or her re-formulate the current problem, or pose additional problems to solve? According to Brown and Walter (1993),"we need not wait until after we have solved a problem to generate new questions; rather, we are logically obligated to generate a new question or pose a new problem in order to solve a problem in the first place" (Brown & Walter, 1993, p. 114). In this way, problem posing and problem solving are naturally related. Silver (1994) referred to this kind of problem posing as "problem re-formulation [that] occurs within problem solving" (Silver, 1994, p. 19). For example, students engaged in the solution of a problem may generate a result that, upon

reflection, calls into question their prior goals and actions; the ways that students resolve the new question often leads to a reformulation of the original problem which may lead to a solution.

Our research questions were: 1. How does problem posing evolve from the solver's on-going interpretations of the problem situation; and 2. How do these posed problems contribute to the solver's problem solving?

Methodology

The case illustrated in this paper involves Sarah, a Mathematics Education graduate student. We observed Sarah's self-generated questions based on her interpretations of the task that she was presented; and these observations formed the basis for answers to the first research question. We answered the second research question by tracing how her problem posing evolved into sophisticated solving. The data consisted of videotaped protocols, the researchers' field notes, and the student's written work. A transcript of Sarah's verbal responses was generated and protocol analytic techniques were used in the analysis (Cai, 1994).

Results

The analysis of the episode with the graduate student, Sarah, includes her posing and solving of a problem she posed from the array she was given (Figure 1): What is the sum of cell entries in any N by N block of numbers from the array?

Find as many relationships as possible among the numbers.

1	2	3	4	5	6	7	8	9	10
2	4	6	8	10	12	14	16	18	20
3	6	9	12	15	18	21	24	27	30
4	8	12	16	20	24	28	32	36	40
5	10	15	20	25	30	35	40	45	50
6	12	18	24	30	36	42	48	54	60
7	14	21	28	35	42	49	56	63	70

Figure 1: Number Array Task

After exploring the array, Sarah reflected on her initial results and looked for other relationships such as the sums of entries in the square blocks (Figure 2).

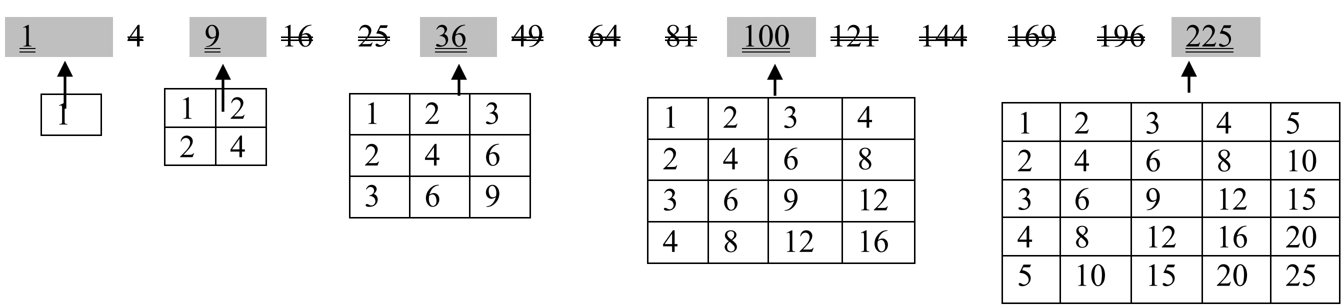

Figure 2: Sarah's Skipping to Find Sums of Block Entries

Sarah: Let's see … *(reflection)* … I was wondering about the square numbers on the diagonal going from left to right. They seem to relate to the sums of these blocks I had earlier *(points to the 2x2, 3x3, 4x4 blocks)*. So, let's check it.

Sarah examined the sum of the entries of each NxN block that contained the square numbers on the diagonal and she developed an informal method to find the sums of the entries of all NxN blocks going down the main diagonal.

Sarah: So, for a 1x1, I get a sum of 1 *(points to the 1 in the upper left corner)*. For a 2x2 *(points to block [1, 2 : 2, 4][i])*, I get a sum of 9 … but what happened to 4? It appears to have been skipped! *(reflection).* Okay, I will write down the sequence of squares of all numbers *(writes the following sequence of square numbers: 1, 4, 9, 16, 25, 36, 49, 64, 81, 100, 121, 144, 169, 196, 225).* So, the first number, 1, tells the sum of the very first matrix, a 1x1. And the first 2x2 has a sum of 9. …. So, I skipped over 4 to get the next sum *(crosses out the 4 in the sequence),* going from 1x1 to a 2x2, a sum of 9. The 4 gets skipped? Interesting!

Sarah has posed a problem: she thinks there may be a relationship between the sequence of square numbers on the diagonal and the successive sums of the entries of NxN blocks. Sarah generalized her 'skip' method to generate the sequence of sums of the entries of all NxN blocks. Sarah then looked to make sense of her method with some further exploration (Figure 3).

Sarah: I wonder why this skipping works? Let's see it another way, for the 6x6, we add the entries in the rows to get 21+42+…+126 = 21(1+2+3+4+5+6) = 21x21 = 441. Do we get 441 by skipping the next 5 in the square sequence? *(Sarah extended her original sequence beyond 225, crossed out the corresponding 'skips,' and got a result of 441 as the next number in the sequence)* (Figure 3). But also, I notice that 21 over here *(points to the factored form 21• (1+2+3+4+5+6))* is the sum of the first 6 numbers in that first row. Yes!

1	2	3	4	5	6	21
2	4	6	8	10	12	42
3	6	9	12	15	18	63
4	8	12	16	20	24	84
5	10	15	20	25	30	105
6	12	18	24	30	36	126

Sum of rows: *21(1+2+3+4+5+6)=21(21)=441*

Skipping in the sequence: Finding the sum for the 6x6 block

15^2	16^2	17^2	18^2	19^2	20^2	21^2

Figure 3: Sarah's Computation of Sums in a 6x6 Block

Sarah tried her idea on an 8x8 block (Figure 4).

Sarah: To find the sum, I bet you just look at the sum of 1 to N and then square the total. Let's try an 8x8. It would be 1+2+…+8 = 36, I don't know why I am adding these individual numbers since I know the sum is (8x9)/2, and then I take 36^2? That comes out to be 1296. Does it check with my skipping here? I first skip 6 over 21 to get 28^2 for 7x7, and then skip 7 more to get the one for 8x8, so 7 more is 35, and the next one is 36! My algorithm works!

1	2	3	4	5	6	7	8	36
2	4	6	8	10	12	14	16	
3	6	9	12	15	18	21	24

Figure 4: Sarah's Computation of the Sum for the 8x8 Block

Theoretical Implications

Our analysis of the problem posing of Sarah suggests important roles that problem posing can play in solution activity. First, problem posing performed in the solution of a problem helps to both broaden the solver's perspective of the original problem as well as expand its scope. This expansion of scope can further help students engage in unexpected generalizing activity that is rooted in students' own goals and purposes. Second, the findings indicate how solvers make conceptual progress through problem posing and thus highlights the importance of self-generated activity for the purpose of extending one's understanding of the problem.

Endnote

[i] We use a bracket notation that lists the top-to-bottom rows of the block being considered. For example, the 2x2 is indicated by the sequence [1, 2 : 2, 4] and a 3x3 block is indicated by the sequence [1, 2, 3 : 2, 4, 6 : 3, 6, 9].

EFFECTS OF COLLABORATIVE REVISION ON UNDERGRADUATE STUDENTS' PROOF VALIDATION SKILLS

Emily Cilli-Turner
University of Illinois at Chicago
ecilli2@uic.edu

Although the ability to determine the validity of a proof is an important skill for mathematicians and mathematics educators alike, there is ample evidence that undergraduate students in a transition to proof course are not proficient at this task. This study employs a teaching intervention called collaborative revision, which refers to the process in which students present a proof they have constructed to their classmates who are encouraged to provide feedback to aid in the revision of the proof. Pre- and post-assessments were administered to students and interviews were conducted to measure students' proof validation skills and to investigate if collaborative revision impacts these skills. Results show that although collaborative revision may not impact students' abilities to identify valid proofs, it does affect the way that students gain conviction about the proof of a statement.

Keywords: Reasoning and Proof, Classroom Discourse

Introduction

This study aims to investigate the impact on argument validation skills of students after participating in a process called collaborative revision in an introduction to proof course. *Collaborative revision* refers to the process in which students present a proof they have written to their classmates and the other students are encouraged to make comments and point out inconsistencies in order to ensure that the proof is valid. Based on feedback from classmates, the student then revises the proof and presents it again, repeating the process until the proof is valid and includes all the relevant details. In this context, this research aims to answer the following research question: To what extent does participation in collaborative revision impact undergraduate students' proof validation skills?

Related Literature

Rav (1999) proposes and Hanna & Barbeau (2009) agree that proofs are of the utmost importance in mathematics, since they, instead of theorems, are the main vehicles in which mathematical knowledge is contained and transferred. Thus, the ability to determine if a given proof is valid becomes an important skill for students. Selden & Selden (2003) highlight that this skill is invaluable for not only future mathematics educators, since they will someday have to evaluate student proofs for assessment purposes, but also for future mathematicians because they will have to examine proofs to learn about new mathematics being produced. Additionally, proof validation is intricately linked to proof construction so students in a transition to proof course need both sets of skills (Selden & Selden, 2003).

Selden and Selden (2003) found that undergraduate students have trouble differentiating between a valid and an invalid proof. In a proof verification task, undergraduate students in a transition to proof course initially judged proofs correctly less than half the time. However, when prompted for reflection about the proofs by the interviewer, the students were able to correctly evaluate proofs at over 80%. The authors conjecture that this may be due to the fact that proof verification skills are not explicitly taught to students and the texts for these courses

include very few proof validation tasks, with those that do exist usually having just a single error to be detected. Alcock & Weber (2005) found similar results with students in an undergraduate real analysis course and write that "this suggests that the ability to validate proofs may be in many students' zone of proximal development and that students' abilities in this regard might improve substantially with relatively little instruction" (pg. 131). Thus, this study aims to determine the effect that making proof validation a part of normal classroom activities will have on students' ability to correctly judge the validity of proofs.

There is much research to support the hypothesis that collaborative learning can greatly enhance student learning about mathematical proof. Yackel & Cobb (1996) note that participation in a community of learners can be a vital part of students' success in mathematics. Additionally, a study by Strickland & Rand (2012) allowed students to submit multiple revisions of proofs in response to teacher feedback and measured the effects on student learning. The teacher comments given were minimal, often just circling a confusing or incorrect passage of the proof, and students were allowed as many revisions as needed. Although the data set was small, on average, students in the revision group did better on the final exam. Proof validation studies (Selden & Selden, 2003; Alcock & Weber, 2005) also show that reflection about written proofs can aid in correctly evaluating the validity of a given proof. Thus, collaborative revision is a way to explore the benefits of combining these proven techniques and this study examines the impact on students' validation skills when using a collaborative revision teaching intervention in an introduction to proof classroom.

Methodology

Context & Participants

This study was enacted at large Midwestern University in courses offered by the Mathematics, Statistics & Computer Science department. The collaborative revision teaching experiment took place in a course correlated with a transition to proof course offered through the Emerging Scholars Program at the university. Students were able to self-enroll in this treatment course and, thus, this is a quasi-experimental study. Since the treatment course was supplemental, the majority of students in the treatment course were concurrently enrolled in the correlated lecture-based transition to proof course, which is the comparison course in this study.

Treatment group participants were drawn from the treatment course in this study and there were 15 students in this group. A comparison group was desired to determine the impacts of the teaching experiment when compared to a lecture-based course. The comparison group solicited students from the comparison course and was comprised of 12 students. Additionally, two students from the comparison group and two students from the treatment group were interviewed to gain insight about what aspects of a proof are convincing to students in each group.

Course Design

Each week students in the treatment course were expected to come to class with a written proof of a statement given by the instructor. At the beginning of class, students were put into small groups (no more than 4 per group) and they discussed the proofs one at a time. During this time, the students were encouraged to carefully read their classmate's proof, writing down things as necessary, and verbalize their impressions of the proofs. Based on the feedback given, the student was responsible for revising the proof and bringing it back in the following week. The treatment course often exposed students to proofs from their classmates, which were neither valid nor written in the most rigorous way. In the context of determining the effects of collaborative revision on student proof validation skills, it was hypothesized that students in this

experimental course would be more proficient at identifying invalid proofs since they would have explicit practice doing this during the course of the semester.

Data Sources

To measure the effects of the collaborative revision on proof validation, a pre and post-assessment was given to all participants. The assessment required students to examine four 'proofs' of a given statement and determine whether each was a valid or invalid proof. The arguments presented to the students were adapted for this study from the proofs given to high school students in Healy and Hoyles (2000) to be appropriate for undergraduates. On the assessment, students were first asked to determine if each proof was valid or invalid, with these terms intentionally undefined to see if students would gain more of an understanding of what a valid proof entails throughout the course of the semester. There were also two more questions on a three-point Likert scale asking students how well they felt they understood each argument and how certain they were about their classification. The same proofs to be validated were given on the pre and post-assessment.

In addition to the assessments, student interviews were conducted with two students in the treatment course and two students in the comparison course. Students were interviewed individually twice during the course of the semester; first shortly after the pre-assessment was administered and again shortly after the post-assessment was administered. The questions asked to students, according to Zazkis and Hazzan (1998), are performance questions, unexpected "why" questions and reflection questions, requiring students to explain why they chose each argument as valid or invalid. During the second interview, students were shown their answers on the pre-assessment and asked to compare to the post-assessment and explain any inconsistencies. This was done to determine what aspects of an argument convinces students, called *student proof schemes* by Harel & Sowder (1998), and if this evolved during this semester.

Data Analysis & Results

Data from the assessments (pre and post) was analyzed to determine the percentage of correct classifications made by each student. Additionally, descriptive statistics were computed for the Likert ratings regarding students' self-reported understanding and certainty about classification for each of the four arguments and independent samples t-tests were done to determine differences between groups (i.e. treatment and comparison). Student interviews were transcribed and analyzed to determine the proof schemes exhibited by each student during the pre and post-interviews.

Consistent with prior proof validation studies (Alcock & Weber, 2005; Selden & Selden, 2003), this study found that students very often incorrectly classified proofs. On the pre-assessment, students in the treatment course were able to classify proofs correctly at an average rate of 60%, while students in the comparison course had a rate of 45%. However, a t-test showed this difference was non-significant ($p = 0.2$). On the post-assessment, the comparison group increased their average correct to 54%, while the treatment group's average remained unchanged. This suggests that the collaborative revision process had little impact on students' proof validation skills. Even though the treatment group did not show an increase in average percentage of proofs correctly classified from the pre to the post-assessment, they did report a significantly better understanding than the comparison group on almost every proof. Additionally, the treatment group reported significantly higher confidence of their classification than the comparison group on two out of four proofs. So, collaborative revision has an impact on students' ability to understand a written proof and their certainty about classifying that proof.

Results from the interviews show that the students interviewed from the treatment group exhibited higher-level proof schemes of Harel & Sowder (1998) from the pre-assessment to the post-assessment, while the proof schemes of students interviewed from the comparison group remained largely unchanged. Table 1 shows the proof schemes that each student interviewed (pseudonyms are used) exhibited during each of the interviews. These results imply that even though collaborative revision has little impact on students' abilities to identify valid proofs, it does impact the proof schemes held by students and how they gain conviction about the proof of a statement.

Table 1: Proof Schemes Exhibited by Students in Each Group During Each Interview

Group	Student	First Interview	Second Interview
Treatment	Stephanie Robert	Ritual Internalized	Transformational Intuitive-Axiomatic
Comparison	James Francine	Empirical Transformational	Transformational Transformational

SUPPORTING INDUCTIVE LEARNING TO REDUCE OVERGENERALIZATION

Nicole R. Hallinen
Stanford Graduate School of Education
hallinen@stanford.edu

Human induction, the process of developing abstract generalizations from specific instances, has been shown to promote positive transfer. By comparing induction to telling the formula in a growth pattern problem, this paper presents evidence that inducing mathematical structure also serves as a buffer against negative transfer, or overgeneralization of the ideas beyond their applicable contexts. The second portion of the paper discusses the necessary conditions that must be met to support students in the inductive learning process. A plan to develop a set of principles to inform the design of inductive instructional activities is outlined.

Keywords: Algebra and Algebraic Thinking, Instructional Activities and Practices, Cognition

In algebra, students are challenged to form generalizations that account for many instances. Similarly, human induction, or the process of engaging in generalization (Ellis, 2007), is characterized by the abstraction of a universal idea from its specific instances.

Learning by induction can help people focus on deep structure, which has been shown to lead to positive transfer, or the appropriate use of ideas in new contexts (Gick & Holyoak, 1980). When learning generalizations, it is important that students know the limits of the application of this structure to ensure that they do not overgeneralize ideas, as in the case of negative transfer (Ross, 1987). Research has not explored the ways induction affects negative transfer.

This paper presents a study that investigates whether induction in algebra supports flexible generalization. Individuals who induce a mathematical solution are compared to individuals who are told the solution and practice on the same problems. The second part of this paper addresses the prerequisite instructional conditions that must be met to help people induce structure.

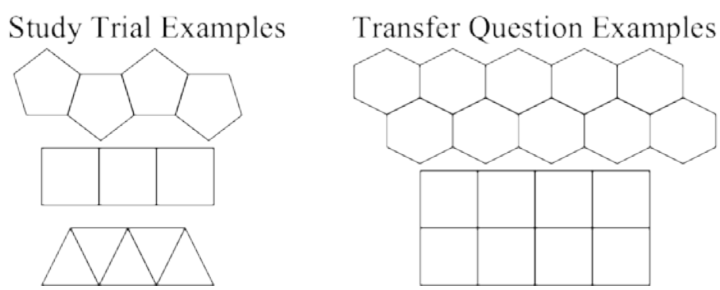

Figure 1: Polygon problem cases (*left*) include different shapes and different numbers of shapes. For the transfer question figures (*right*), the perimeter formula must be adapted.

The Polygon Problem

The learning topic was growth pattern problems – algebra tasks that illustrate the importance of abstraction and the utility of generalizations. These problems directly relate to Common Core Standards (National Governors Association Center for Best Practices, 2010) and are stressed in professional development (e.g. Koellner et al., 2007). The polygon problem asks the solver to find the perimeter of a row of shapes (see Figure 1). The inductive problem-solving approach requires the learner to consider instances to build a rule that accounts for the two key variables: the number of

shapes (n) and the number of sides in each shape (s). One alternative instructional approach is to provide a rule at the start. A form of this algebraic formula is: $(s - 2)n + 2$.

To test whether participants would generalize the formula and transfer to new contexts, the pattern was modified to include two rows of shapes as shown in Figure 1. In these transfer questions the perimeter formula must be adapted to account for the additional shared sides.

Study 1: Experimentally Comparing Induction and Telling

Forty adults (M= 22.75 years) participated in a 45-minute study that consisted of three 18-trial blocks and two transfer questions, as outlined in Table 1. Each block contained problems ranging from 3-10 shapes with 3-6 sides (triangles through hexagons). Each trial was displayed on a computer and participants had unlimited time to determine the perimeter.

Table 1: Overview and Results for Induction and Telling Conditions

	Block 1 Count	Block 2 Treatment	Block 3 Told	Transfer Questions	Transfer Strategy Use	
Induction Condition n = 20	Count 94% correct	**Induce** 89% correct	Told 95% correct	Adapt formula to new patterns:	Correct	11
					Overgeneralize	3
					Other	6
Told Condition n = 20	Count 92% correct	**Told** 94% correct	Told 97% correct		Correct	6
					Overgeneralize	12
					Other	2

Time →

Participants were randomly assigned to condition: Induction or Told. In Block 1, all participants counted the perimeter to become familiar with the problem. In Block 2, Induction participants searched for a formula to use with all shapes and all numbers of shapes. After finding the formula, they continued using it on remaining Block 2 problems. Told participants were shown the perimeter formula with a worked example before Block 2. The variables were defined, but the applicability of the formula was not elaborated. Told participants calculated the perimeter using this formula. For Block 3, all participants received the same formula. For the Told condition, these instructions were identical to Block 2. Induction participants were shown the same presentation the Told condition had seen for Block 2. After Block 3, participants talked aloud during two paper-based transfer questions.

As shown in Table 1, all individuals were quite accurate throughout. There were no significant between-group differences. Searching did not significantly diminish accuracy.

During Block 1 (Counting), Reaction Time (RT) varied directly as a function of perimeter ($R^2 = 0.96$, $p < 0.01$) with no significant between-group differences: as the perimeter increased, participants took longer to count. As this correlation is not significant in later blocks, this serves as a manipulation check, indicating that participants counted during these trials and, notably, did not

naturally induce a formula to solve for the perimeter. In Block 2, searching for a formula took significantly longer than directly applying one. However, after finding the rule, Induction participants' RTs dropped fivefold, from minutes to seconds per problem. By Block 3, all participants used the provided formula and mean RTs did not differ by condition.

In summary, accuracy is not affected by searching, but induction takes significantly longer than using a formula at the outset. The transfer question results illuminate why one would choose to teach inductively, as it appears to be a less efficient strategy.

Participants' responses to the transfer questions fall into three categories: correct adaptation to the new context, overgeneralization (directly applying the formula without any changes), and other (which includes counting). The breakout by instructional condition is shown in Table 1. There is a significant interaction of solution type by instructional treatment ($\chi^2 = 8.87$, $p = 0.01$). Told participants are more likely to overgeneralize and Induction participants are more likely to correctly adapt to the new context.

Discussion of Study 1

The main benefits of induction are seen at transfer. Although Told participants execute the formula efficiently, their knowledge is brittle and they do not develop a sense of the range of examples that it fits. These individuals are more likely to overgeneralize the formula to new situations. Inducing the rule seems to block negative transfer.

However, there are two risks to induction. First, it takes time to induce a pattern. Overall, Induction participants showed the characteristic extreme drop in problem-solving time once they had induced the rule (Schwartz & Black, 1996). Eventually Induction individuals do become fluent users of the formula, as evidenced by shorter reaction times and stable accuracy in the Induction condition after discovering the formula. Being told the formula after engaging in generalization did not hurt, but participants who were told without any opportunity for induction were susceptible to negative transfer. Second, some participants may never induce a useful rule (Gick & Holyoak, 1980). These results highlight a difficulty designing inductive instructional environments: not everyone is guaranteed to discover the phenomenon in question.

Prerequisites to Inductive Learning

Task Orientation

To promote learning through induction, teachers and learning environments must explicitly instruct students to adopt an inductive problem-solving orientation. As seen in Study 1, seeing deep structure does not always happen naturally. Participants did not induce the pattern during the counting trials; they only found the formula when explicitly asked to search for it. Study 1 also demonstrated an important truth with instructional implications: directly telling a formula does not ensure that students will think critically about its meaning. Even when people can fluently apply a formula, they may not understand the underlying structure of the generalization and therefore not have a sense of the scope of situations to which it may apply. Asking students to engage in generalization entails developing clear, explicit instructions to orient them to the task of creating a mathematical expression to account for many instances.

Materials

Even with the right task orientation, students need well-organized materials to support inductive thinking. As a trivial example of poorly chosen materials, if students were only presented with example rows of squares in the polygon problem, it seems unlikely that they would naturally extend their generalization to other polygons without any prompting. By systematically sampling the space of possible rows of shapes, a more comprehensive set of cases would be fruitful in encouraging generalization. Instructional examples chosen to highlight meaningful variation among the set are called contrasting cases. Contrasting cases juxtapose two or more examples that vary on at least one

dimension. For example, in the polygon problem, perimeter varies with respect to two dimensions (*n* and *s*) and changing either variable affects the outcome. When contrasting cases are used in instruction, the students' task is to search for an underlying pattern to explain all cases. This differs from sequential problem solving, where students often treat each question as a separate learning task and fail to notice the commonalities across each instance (Star & Rittle-Johnson, 2009). To help students learn how variables are interrelated, contrasting cases should be used to show mathematical structure instead of merely revealing differences in variables. For example, contrasting cases designed to highlight a ratio relationship must emphasize that the two parts of the ratio are interdependent – when the numerator changes, the denominator must change correspondingly to maintain the underlying ratio. In previous work, contrasting cases have been developed for concepts such as statistical variation (Schwartz & Martin, 2004) and for ratio in the topic of density (Schwartz et al., 2011).

What needs to be included across a set of cases such that students can induce their deep mathematical structure? By systematically varying the presentation of patterns in inductive tasks, research can test hypotheses about which information is necessary and sufficient for learning. These studies involve examining the role of presenting interactions between variables; i.e. for ratios, is it better to hold the denominator constant and vary the numerator or would it be optimal to present cases that show concurrent variation in both dimensions?

Future Work

Data collection has begun to compare several sets of cases designed to help students find ratio relationships among variables in early physics domains. This study investigates the best way to present variation along dimensions in these problems with multiple interrelated factors. Preliminary results suggest that highlighting interactions between variables helps learners discover the importance of mathematizing these relationships. This work is intended to inform practice by creating design principles to aid educators in the construction of inductive learning activities. It is the hope that these principles will encourage widespread adoption of induction activities in math classrooms. Contrasting cases offer a potential way to catalyze subsequent learning because they help students grasp key relational structures. As shown, induction is a powerful way for people to find new-to-them mathematical structure, which in turn, helps them benefit from other instruction and leads to appropriate transfer to new contexts.

TEACHING FIRST-YEAR MATHEMATICS UNDERGRADUATES TO THINK MATHEMATICALLY

Nadia Hardy

We present an ongoing design experiment *for the teaching of an undergraduate mathematics course called* Introduction to mathematical thinking. *The goal was to design a rich mathematical environment where students will be able to develop mathematical thinking. Preliminary results suggest that students actively engaged in learning to think mathematically.*

Keywords: Advanced Mathematical Thinking, Reasoning and Proof, Design experiment

In this report we discuss partial results of an ongoing *design experiment* (Brown, 1992; Collins et al., 2004) for the teaching of a first-year undergraduate course called *Introduction to mathematical thinking*, compulsory for students in the Major in Mathematics and Statistics program. These students have a (typically weak) background in college calculus and linear algebra and haven't taken courses that require proving. One of the authors taught the course previously: following the institutions' normal approach, the course focused on proving using algebra and arithmetic as the topics for exemplifying proving techniques and the writing of proofs. This research is mostly motivated by those experiences, where students, although able to write simple proofs, didn't seem to understand why these were necessary or why they were actually *proofs* of anything. The new course was designed with the goal of providing a rich learning environment where student could develop mathematical thinking as defined by model that arises from combining a model of *theoretical thinking* (Sierpinska et al., 2002) with aspects of *metacognition* (Schoenfeld, 1987).

To Think Mathematically

Without ignoring previous contributions to the characterization of mathematical thinking, we consider Sierpinska et al.'s (2002) model of *theoretical thinking* (TT) and extend it to a model of *mathematical thinking* by including aspects of *metacognition*, based on (Schoenfeld, 1987).

Sierpinska et al.'s model is based on Vygotsky's work. In this model, TT is characterized as *reflective* (RT), *systemic* (ST) and *analytic* (AT). The aim of the reflective thinker is not to get things done, rather to reflect on and further investigate a task at hand. RT is about curiosity and challenging one's own mind. ST is thinking about systems of concepts, where meaning is established based on relations with other concepts. The systemic thinker is aware of context and structures and of the conditional character of statements; seeking to uncover implicit assumptions and study logically conceivable cases; concerned with validity and consistency. The analytic thinker is sensitive to symbolic notation, specialized terminology and the structure and logic of mathematical language; the analytic thinker understands the distance between symbol and object.

Among many aspects of metacognition, Schoenfeld (1987) highlights *self-regulation* as having direct implications for mathematics education. The self-regulated problem solver thinks before doing, making sense of the problem at hand. Self-regulation is also about planning and self-monitoring: keeping track of how things are going during a problem solving process. Based on these ideas, we characterize a *mathematical strategist* as someone who efficiently uses self-regulation.

From this perspective, we say that an individual *thinks mathematically*, when in his or her *behavior* we can see evidence of uses of theoretical thinking or mathematical strategies.

Course Design

Based on *design experiment* methodology, we drastically changed the traditional undergraduate mathematics classroom into an *intentional learning environment* where students acted as researchers and as teachers. The curriculum was changed to focus in *depth* on a few *recurrent themes*; a set of activities (in- and out- of class, and online) were created to engage students in mathematical thinking. Dynamic assessment tools were used to monitor progress, focusing on students' uses of mathematical thinking.

Each class, the students worked in small groups (3 up to 5 students) on 2 or 3 activities. These activities included problems easy enough so that students could mathematize them and make conjectures about their solutions but difficult enough so that they couldn't easily (or at all) construct a mathematical proof; problems for which they couldn't provide a definite answer; activities on the notion of truth, definitions, axioms; unpacking statements (Selden & Selden, 1995) and deconstructing proofs. Time was allotted for whole class discussions. The ultimate goals of these activities were to engage students in situations where we believe mathematical strategies, RT and ST are particularly useful, and in oral and written argumentations in which we believe ST and AT strongly come into play. The idea of concepts, techniques, etc. being discussed *on-demand* played an important role in the design of the activities. Approximately every 3 weeks the students had a quiz (4 in total) and there was a final exam at the end of the session – in every case, the students were given time to discuss the assessment problems in groups before engaging in writing individual answers. Also, a web site for the course was set up, including an online assessed activity (*weekly forums*). Students were expected to post questions, problems, solutions, or ideas that *meaningfully* contribute to the ongoing discussion. They could initiate a thread or respond to peers' or teachers' postings. The notion of *meaningful* was constructed through practice. Postings were typically triggered by the in-class activities of the corresponding week.

The course is 13 weeks long, with 2 weekly sessions of 75 min each. There were 28 students enrolled (of which 27 gave consent to the use of their data). A professor and a TA were present every class (we write *teachers* to refer to both of them).

Operationalization of the Model of Mathematical Thinking

To analyze students' thinking, we have operationalized the model for mathematical thinking by making a list of *behaviors* that would provide evidence that the individual is thinking mathematically. This list of behaviors is not exhaustive; it serves as a guideline for identifying and characterizing mathematical thinking in collected data – the data itself and further analysis may add to the list. Examples of these behaviors are: (a) evidence of mathematical strategies: efficient use of self-regulation and self-monitoring, considering different approaches, analyzing the problem (before doing), modeling, constructing examples (simple, pathological); (b) evidence of RT: actively seeking explanation and understanding, valuing one's personal effort and discovery, persistence in dealing with tasks, seeking generalization; (c) evidence of ST: referring to definitions, context and systems of concepts, showing concern for validity, engaging in proving or reasoning; (d) evidence of AT: a concern with the correct use of symbols and language, a concern towards disambiguation and specificity, valuing different representations.

Analysis, Results and Discussion

We consider three sources of data: students' postings in the weekly forums, students' answers to quizzes and final exam, and notes taken by the teachers during class or immediately after class trying to faithfully record what a student had said. Presently, we are using these sources to construct a *mathematical-thinker-profile* for each of the 27 students. Then, students will be classified according to these profiles. In what follows, we discuss preliminary results.

From the first class, students actively and loudly engaged in the (non-graded!) in-class activities and contributed to weekly-forums more than was required, participating in long discussion threads or sharing pertinent resources they found online. The composition of groups was mostly stable through the session and formed during the first classes without any intervention from the teachers. All groups had "leaders" – mathematically stronger than their peers. They would lead the discussions in class and also be the first to post in weekly forums. While the role of the leaders seemed to be to direct the "followers" attention towards meaningful aspects of a problem at hand, the role of the followers was to ask questions and challenge the leaders' approaches. We believe that followers where somehow mimicking the teachers interventions: teachers would listen to what a group was discussing and then challenge their approach with "what if…" type of questions. In our research, we don't account for how the leaders/followers positioning aroused but we do point out that while whole classroom discussions probably reinforced leaders' positioning, the role of followers was validated by the local interventions of the teachers. This structure promoted a research-work approach in each group, and a teaching-learning environment where stronger students will explain mathematical ideas, concepts and procedures to the weaker students. In this context, inside and outside the classroom, students were in control of the knowledge being shared: concepts were discussed on a need-to-know basis responsive to students' needs, typically by leaders, who would provide explanations to their groups but would also go to the blackboard and provide explanations to the whole class; teachers would intervene only when no one in the classroom could provide a mathematically valid concept, solution, justification, etc., to clarify, to provide alternative explanations or strategies, and to *institutionalize knowledge* (Chevallard, 1999).

The analysis of students' postings and answers to quizzes show that students engaged in mathematical thinking as defined by our model. The goal of the analysis is to provide a characterization of students as mathematical thinkers (*profile*) and to account for the development of mathematical thinking features. A full data analysis will be presented at the conference. We now provide a few examples of how data was analyzed and refer to the activities that triggered them. Each quote below comes from a different student.

During the first week, the discussion focused on the meaning of the logical operators "and" and "or", and how their mathematical meanings are different/similar to the uses we give them in everyday language. That week, a student posted: "If we look at the inequality $f(x)g(x)<0$ (where $f(x)$ and $g(x)$ are continuous and real), their products must produce a value that is less than 0. Specifically, $f(x)$ has a negative value <u>and</u> $g(x)$ has a positive value ($f(x)<0$ & $g(x)>0$) <u>or</u> $f(x)$ has a positive value <u>and</u> $g(x)$ has a negative value ($f(x)>0$ & $g(x)<0$)." Our analysis: The student stated the conditions under which the claim is true (ST); he created an example of a complex use of conjunction and disjunction (RT); and he detached symbolism from the objects discussed in class (integers) to create an example about different objects (AT).

In quiz 1, given the 7 bridges of Königsberg, students were asked whether a walk using each bridge exactly once is possible or not. Most groups engaged in an exhaustion process to conclude that the walk was not possible but many engaged in an "efficient" exhaustion (e.g., taking advantage of the symmetry of the problem), even when they had actually gone through every

case, they went back to improve the method (RT). Once the groups found that the desired walk cannot be done, the activity was extended to discussing under which conditions it would be possible. Their postings were a display of mathematical strategies. Some students wrote:

> "We thought that changing small aspects of the problem would make us figure out why [the walk] was not possible in the first place, by making special cases."
>
> "Once we realized [the walk] was not possible we went on to try configurations that did [allow for such a walk]; moving bridges and islands alike. [But then, we] started to look at it less in terms of where to put the bridges and more in terms of how many to put leading from one island to another."

The activity provoked other modes of thinking as well. E.g., showing concern for validity (ST), one student posted, "No, we didn't solve the problem, because we couldn't come up with logical statement[s] that describe exactly why the answer is No."

During the third class, the students were posed the question "what is the sum of the interior angles of a polygon". Without being prompted to, groups engaged first in discussing what a polygon is. This particular case was an overwhelming display of mathematical thinking, which included: discussions about definitions and connections to previous knowledge (RT and ST), discussions on notation and representation (AT) and the construction of simple and of pathological examples and of counterexamples (mathematical strategies).

The design had unexpected consequences: many students reported on a shift of their beliefs about mathematics (another aspect of metacognition that Schoenfeld highlighted as having implications for mathematics education). E.g., a student posted: "Before […], mathematics was simply numbers and formulas to me. I never really gave much thought to how those formulas and laws came to be. […] This class really got me thinking, how were these proven, what did it take to get to that proof, and even if it has been proven, is it really possible to show that a certain formula will work with everything?"

As an example of how students took control of content and knowledge, we recall that the notion of *meaningful post* was constructed through practice. By the fourth week, students were pointing out if a posting was unclear, incorrect, or if they couldn't see its relevance.

Whether students were already mathematical thinkers or if they became so as they engaged in the activities is something we can't answer at this point. Individual cases might be very different. Our conjecture is that in either case, there was *improvement*. Nevertheless, our analysis of data shows that the design provided students with *opportunities* to engage in mathematical thinking; something that doesn't seem to be a commonality in first-year undergraduate mathematics courses – and students did take advantage of these.

In this study, we describe the effect of participating in an advanced course in proofs and number theory on gifted high school students' mathematics self-efficacy. The focus of the course was on learning how to prove theorems, and to that end, the instructor modeled higher order mathematical thinking with the intent of helping students develop mathematical habits of mind. We measured self-efficacy with pre- and post-surveys that included both Likert-scale items and open-ended question to determine ways self-efficacy was affected by course taking and whether effects influenced students' choice of college math courses.

Keywords: Affect, Emotion, Belief, and Attitudes, Reasoning and Proof, Advanced Mathematical Thinking

Introduction

The purpose of this study was to examine mathematical self-efficacy beliefs of high school students enrolled in an advanced mathematics course titled *Proofs and Problems in Number Theory and Algebra* (PPNTA). In this course, students were expected to engage in higher order mathematical thinking, develop skill in constructing proofs and showing counterexamples, participate in intellectual argument with their peers, and work both collaboratively and individually to solve difficult mathematical problems. Although the mathematically gifted students in this study generally have high math self-efficacy, their prior math experiences have emphasized calculation and content-specific objectives. This course was significantly different from the other advanced math courses students have completed because it focused on abstract properties such as elegance in proofs and metamathematics. We were particularly interested in studying self-efficacy in this context and with these students because of the way self-referent beliefs affect how students approach tasks, set goals, and persist when working through challenging tasks (Bandura, 1997).

According to Bandura (1994), self-efficacy refers to the beliefs individuals have about their ability to achieve a goal at a given level of performance. Self-efficacy affects the choices people make, and thus students with high self-efficacy typically make choices that lead to achievement, while students with low self-efficacy may engage in behaviors that undermine their success (Pajares, 1996).

Researchers have determined that gifted and high ability students typically have high self-efficacy and have a more accurate perception of their ability than do students of average aptitude. In our earlier studies (Hendricks & Millman, 2012), we found statistically significant differences in gifted students' pre and post course math self-efficacy. Further, there was less fluctuation in self-efficacy for students who were comfortable with the abstract nature of the course, whereas students who were more comfortable studying concrete concepts said changes in their self-efficacy were dependent on the difficulty of individual topics covered during the course. Though Pajares (1996) explains that gifted students' self-efficacy relies more on ability than performance, our findings did not bear that out. Rather, our results revealed that mathematically gifted students' comfort level with the abstract

nature of the course was a better predictor of self-efficacy than was cognitive ability, which was high and consistent across students in the course.

Methods

PPNTA Course

The course was developed in partnership between Georgia Tech's Center for Education Integrating Science, Math, and Computing (CEISMC) and a public charter high school with an emphasis on math, science, and technology. Funded by Georgia's Race to the Top award from the U.S. Department of Education, the course was taught by a Georgia Tech doctoral student in Industrial and Systems Engineering studying Algorithms, Combinatorics, and Optimization. CEISMC's director (a co-author of this paper and professor of mathematics) collaborated with the course instructor to plan the PPNTA course and made several classroom observations during the semester and delivered lectures. The intent of the 18-week course was to help students discover that mathematics is not based solely on memorization nor is it fundamentally about calculation. To accomplish this, we created an *explore, generalize, prove, think* environment that parallels the culture of that of mathematics researcher. The course included topics such as equivalence relations, topology, and elementary Lie groups—mathematical ideas that go beyond the abstraction of modular arithmetic. Other course topics are basic properties of integers; divisibility and prime numbers; the Fundamental Theorem of Arithmetic; linear Diophantine equations; equivalence relations and their applications; basic properties of polynomials; divisibility of polynomials, divisibility methods, and roots of polynomials; combinatorics; elementary group theory; public key cryptography; and problem solving with computer programming. In studying these topics, students were expected to (a) identify what makes a mathematical proof correct, (b) learn commonly applied proof techniques, (c) develop proficiency in reading and writing mathematics in general and as proofs or counterexamples, and (d) apply problem-solving methods to find solutions and demonstrate the accuracy of their methods.

Participants and Setting

Twenty-eight 12^{th} grade students—18 males and 10 females—were enrolled in the course. Eleven of these students had parental consent and/or assented to be in this study. Of these students 9 completed both the pre- and post-surveys, and our results are based on these students. Six were male, and three were female. Four students were Caucasian (44.4%), 3 were Asian (33.3%), and 1 student each were Hispanic and Middle Eastern.

The study took place at a public charter high school that emphasizes math, science, and technology. Approximately 600 students are enrolled in grades 9 through 12, including 40% Asian, 29% Caucasian, 18% African-American, and 8% Hispanic. The majority of students (74.5%) are in gifted programs. The school offers 17 Advanced Placement (AP) courses, including those in calculus, statistics, physics, biology, chemistry, computer science, and humanities. Our participants were high ability students, and most had completed college-level calculus before enrolling in PPNTA. At the beginning of the course we asked students about their general mathematics capability; 4 said they were *extremely capable*, and 5 said they were *capable*. Five students intended to pursue a university degree in engineering, including 2 double majors in computer science/electrical engineering, 1 in biomedical engineering, one in mechanical engineering, and 1 in general engineering. Two students planned to pursue degrees in computer science, and 2 planned to study chemistry.

Data Collection

Changes in students' mathematical self-efficacy were measured using pre and post self-efficacy scales we developed for an earlier study (Hendricks & Millman, 2012). Items were developed based on Bandura's *Guide for Constructing Self-Efficacy Scales* (2006) and were aligned to course objectives. For example, students rated their confidence in areas such as *identifying fallacious*

reasoning in proofs and *learning different methods to construct proofs*. Following Bandura's guide, pre- and post-survey items related to what students *can do* to measure their perceived capability. On pre-surveys, students also were asked to rank their confidence in achieving each course goal. To clarify, on the pre-survey, students ranked both their current ability for each course goal as well as their confidence that they would be able to reach each goal.

The pretest, given near the beginning of the course, included 13 items related to course goals. For each item, students ranked their self-efficacy on a scale from 0 (low self-efficacy) to 100 (high self-efficacy) for both their current ability for the course goal (*How confident are you that you can already construct valid proofs?)* as well as their confidence they would be able to reach the goal (*How confident are you that you can learn to construct valid proofs?*). The post-survey contained identical items but students only ranked their current ability. The post-survey also contained 11 items that related to students' experience in the course.

Results and Discussion

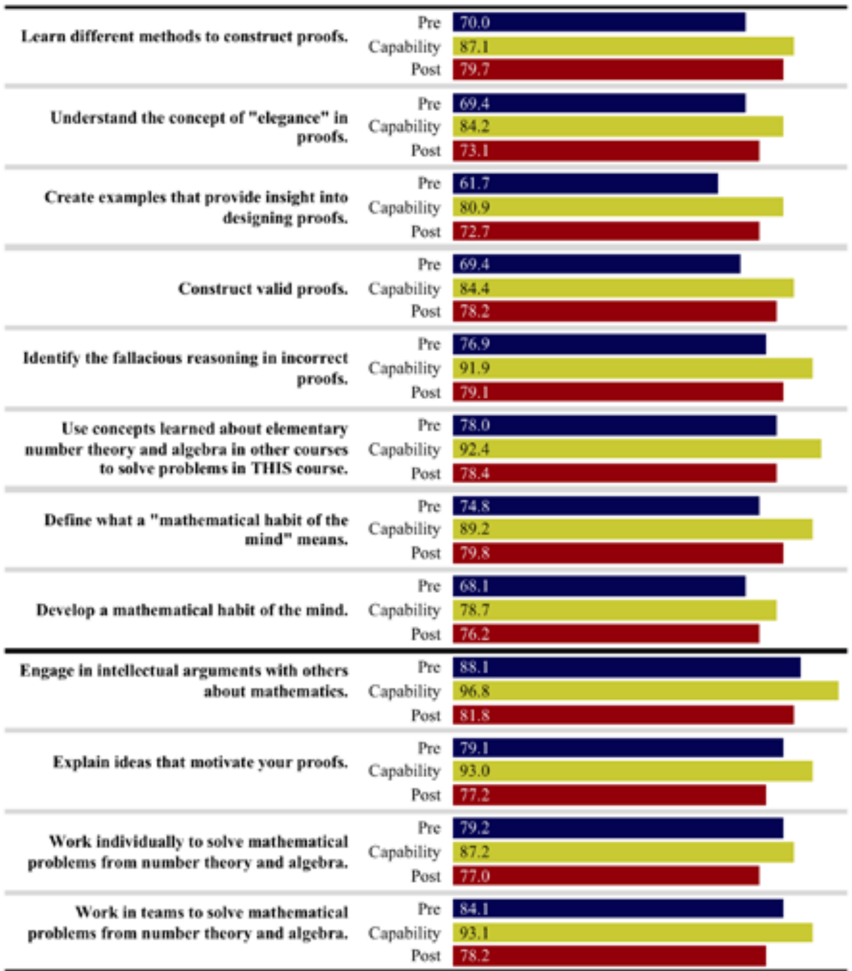
We compared students' self-efficacy beliefs at the beginning of the course (pre self-efficacy), their self-efficacy related to reaching course goals (potential capability), and their self-efficacy at the end of the course (post self-efficacy). Because of the small sample size (n=9), we have provided descriptive statistics only. Students' average pre self-efficacy (SE) across all SE items was 75.5, and their average potential capability was 88.7. However, on the post-survey, average SE was 78.0, which was almost 11 points lower than their estimated potential and just 2.5 points higher than their pre-SE. We saw positive pre-post changes in SE on 8 items, negative changes on 4 items, and no change on 1 item (see Table 1). SE increased most on the items *Create examples that provide insight into designing proofs* (+11) *Learn different methods to construct proofs*. (+9.7), *Construct valid proofs* (+8.8) and *Develop a mathematical habit of the mind* (+8.1). The greatest areas of decrease were on items *Engage in intellectual arguments with others about mathematics* (-6.3) and *Work in teams to solve mathematical problems from number theory and algebra* (-5.9).

Seven of the 9 participants said their mathematics confidence had increased due to their experiences in the course. One student's confidence decreased and another's stayed the same. Students whose confidence increased said they learned to think critically and reason through problems. One student explained, "*I felt like every problem we encountered in this class was a familiar one, but we gained a new insight on how that problem is solved or why a theorem works*." Another wrote, " *I had the chance to examine the reasoning behind the math that I've been using and understand why the formulas and theories work*."

In describing the course a student stated, "I *learned much more about how mathematics works than in any other class. I enjoyed all of the problem sets because they felt more like a challenge rather than another 'problem' to solve*." Other students also described the challenging nature of the course. One student, for example, stated "*It was a bit difficult to follow sometimes because there was a lot to think about all at once but it was cool once I got it*." Another said the course "…*was very frustrating when I fell behind and did not know what was going on, but those moments when I finally [understood] a problem were interesting and fulfilling, maybe even fun*."

Three students (two females and one male) said taking the course sparked their interest in taking similar courses in college. A female student wrote, "*Even though I struggled, I know this kind of math exists and it can help me decide what kind of class I want to take in college*." A male student planning on a double major in chemistry and math wrote, "*The course sparked my interest in proofs and other fields of rigorous mathematics, and I am excited to take more advanced math courses in college*."

Table 1. SE Changes Pre, Capability, & Post



As described by other students in previous semesters, students both enjoyed and were challenged by this course. For example, when asked what she liked best and least about the course, a student said, "*Understanding a problem after working on it for a long time; NOT understanding a problem after working on it for a long time*." Another student wrote, "*I liked it best when I was completing a proof and I'd look back on it and marvel at how elegant and simple it all was in hindsight. I liked it least when I found myself completely stumped by a difficult proof.*"

Though our sample size was small, results of this study are similar to our findings with two other groups of students. Students found the course challenging, they tended to overestimate their capability, but completing the course increased most students' mathematical self-efficacy. Further, a third of the participants in this study, including two females, said their experience in the course had affected their decisions about the math courses they will take in college. As enrollment for the course continues to increase, our goal is to replicate the study with a larger group of students. Further, we plan to track students into college to determine whether they do indeed choose to take advanced math courses based on their experiences in the PPNTA course.

NOTE: This research is Funded by the Georgia Department of Education through the U.S. Department of Education *Race to the Top* grant.

This paper describes opportunities and challenges teaching assistants (TAs) experience when they provide feedback on mathematical modeling problems. Eight TAs were interviewed regarding issues they experience while working for engineering courses in which about 2000 undergraduates create mathematical models to solve realistic problems and communicate their solutions. The opportunities and challenges are associated with the following factors: the process of providing feedback; TAs' perspectives of modeling problems; and professional training to learn how to provide effective feedback on students' solutions to mathematical modeling problems. The specific factors that influence TA's abilities to provide formative feedback are discussed and the use of a reflective practice that enables students to understand what abilities they gain through mathematical modeling activities is suggested.

Keywords: Assessment and Evaluation, Modeling, Problem Solving

Introduction

It has been a challenge to create learning environments where students create, revise, and develop their intuitive mathematical thinking to more refined ways of reasoning (Rasmussen & Blumenfeld, 2007). At the undergraduate level, diverse student populations contribute to the challenge (Holton, 2001). At large research institutions, the critical role teaching assistants (TAs) play in helping large and diverse student groups also adds to the challenge. At Purdue University, TAs help approximately 2000 first-year engineering students each semester solve mathematical modeling problems. By examining the factors that influence TAs' ability to help students solve MEAs, this study aims to answer the following research question: What affects TAs' abilities to provide feedback on students' solutions to mathematical modeling problems?

Theoretical Framework

Model-Eliciting Activities

Model-Eliciting Activities (MEAs) are mathematical problems set in real-world contexts that challenge student teams to create a mathematical model and communicate their mathematical thinking (Lesh, Hoover, & Kelly, 1993). MEAs are used not only in mathematics education but also in other disciplines such as engineering and science education (Hamilton, Lesh, Lester & Brilleslyper, 2008). The six design principles (Lesh et al., 2000) are used to develop MEAs for Purdue University's First-Year Engineering (FYE) courses (Diefes-Dux et al., 2008). Student team work is assessed along four dimensions (Diefes-Dux et al. 2012). The *Mathematical Model* dimension focuses on whether or not the solution addresses the mathematical complexity embedded in the situated problem. The *Modifiability* dimension focuses on the justifications supplied for the mathematics used to solve the problem. The *Re-usability* dimension focuses on

the brief communication of the problem and its solution, and the *Share-ability* dimension addresses whether or not it is easy for the client to follow and apply the solution.

TA Training and Feedback Process

TAs have become integral to the success of introductory classes at universities (Luft et al., 2004). However, little research has inquired into the challenges faced by TAs and their beliefs about teaching (Speer et al., 2005). Owens (2011) noted one of the challenges TAs faced was working beyond the scope of their abilities, which could lead to students' misconceptions. Owens' concern is related to TAs' role in providing formative feedback because their feedback affects how students move forward from misunderstandings. Formative feedback is "information communicated to the learner that is intended to modify the learner's thinking or behavior for the purpose of improving learning" (Shute, 2008, p.1). By learning how to provide formative feedback, TAs will be able to identify student problems, relate their performance to the goal, and provide information that will move students towards that goal (Dale, 2006). Identifying factors that positively influence TAs' ability to provide feedback and creating an environment that is conducive to the TAs' success are essential steps in implementing real world mathematical modeling activities in the classroom.

Methods

In Fall 2012, there were approximately 90 TAs for two FYE courses that worked with a total of 2000 FYE students. Some of TAs' common responsibilities included preparing for class, helping with in-class activities, attending training, and grading. Thirty TAs volunteered for this study. From these, four undergraduate teaching assistants (UTAs) and four graduate teaching assistants (GTAs) were randomly selected to participate in this study.

The eight TAs participated in a semi-structured interview that varied in length from 45 to 90 minutes. The interview questions were divided into seven categories: background information, hiring process, overall experience, thoughts on MEAs, training, expectations and responsibilities, and support and mentoring. These categories were developed after reviewing literature on the implementation and assessment of mathematical modeling activities (Diefes-Dux et al., 2008).

Interviews were audio recorded and transcribed. The research team identified the interviewees' responses in the transcripts that were relevant to MEAs and discussed factors that affected the TAs' abilities to provide feedback to MEAs teams' solutions. These responses were coded as different factors affecting their performance (e.g. unclear grading rubric and the discussion portion of training). The factors were then grouped together based on similarities, which resulted in nine categories of factors that TAs discussed. Three categories were closely related to our research question and discussed by more than half of the TAs.

Results and Discussion

The three main categories were feedback process, training, and their perspectives of MEAs. The UTAs are referred to as Uriah, Ursula, Ulysses, and Udo, and the GTAs are referred to as Gail, Grace, Greg, and Gus. All names used are pseudonyms, but are gender appropriate.

Feedback Process

All of the TAs discussed aspects of the feedback process that had positive and negative effects on their ability to provide feedback. The TAs discussed struggling with the lack of a system to adjust MEA team scores to individual scores, the concept of quantifying subjective work, and the scores on the final response being the only ones that affect students' grades. Gail explained her difficulty in scoring students' work:

> *We're taking a very subjective assignment and trying to turn it into a something that can be quantifiable and I am not saying it can't be quantified, it's just like I said, if I were to look at one team individually I can use the rubric it makes sense, but if I am going to look at this team in comparison to other teams [it doesn't work], which is not suggested, but as a GTA it is hard to not look at compared to how other people are doing.*

Training

All of the TAs discussed various aspects of the MEA training. The two main components of training are the online and face-to-face portions. Most of the TAs found it challenging to solve the MEA online prior to face-to-face training, but rewarding because it enabled them to better understand the potential problems and challenges that the student teams may face. TAs' perceptions of calibrations, which involve comparing their feedback to that of an expert, were mixed with positive and negative feelings. One TA noted that comparing their feedback to the experts helped them better understand their own successes and shortcomings. Other TAs noted that there were either too many calibrations and/or the online training required too much work.

On the other hand, TAs generally found face-to-face training helpful. They indicated the discussion time, the expert's opinions, potential solutions, opportunities to ask questions, and information about providing constructive feedback the most helpful features of this forum. Greg discussed some components he found beneficial about training:

> I think that [calibration] helps a lot because then you know how specific of details they want and you know how well you're doing compared to someone who knows what they're doing. ...you also have your own MEA to write, which is a good idea because then you know ...where they [students]'re gonna have trouble. ...I think [the face-to-face training] is good because then we actually get to ask questions and go into detail about different examples of how to grade ...and then we can actually practice in class.

Some TAs stated that the lecture incorporated into training contained too much content, which made it difficult to stay focused and remember the information. The major criticism that a few TAs had about the training was that it did not cater to varying levels of expertise resulting in repetition, especially for experienced TAs. Uriah proposed the following solution:

> I feel [having two trainings] would be better. The first one put it into like here is generally what goes on in an MEA and the second this is what we are working on. [Then] you're only learning things you need to learn.

TAs' Perspectives of the MEAs

The majority of the TAs discussed their perspectives of MEAs as a pedagogical tool in the FYE courses as well as issues with the implementation of this tool. The TAs who discussed the use of MEAs as a pedagogical tool considered them generally effective. However, some TAs discussed that the FYE students and sometimes even they themselves did not understand the purpose of the MEAs, which contributed to lack of student motivation and/or misunderstandings of TA feedback. Uriah discussed his perspective on the purpose of MEAs:

> I am not sure I fully understand the purpose of MEAs… I know there is a reason they are there… I don't think [students] understand why they are doing [MEAs]…their immediate reaction is well why? What am I gaining from this?…I don't think they understand the purpose behind it, like if there is a greater meaning to it.

The TAs also indicated that unclear language results in students' misunderstanding of the purpose of the assessment dimensions and feedback provided by TAs, but students have positive perspective on MEA once they know the purpose. Grace stated the following regarding MEAs:

> I like the overall intent of MEAs. I think it is actually a good method. And you're walking students through ...how to develop a solution process. How do you implement that? But it's also very frustrating. Just because students you know don't seem to get it at first so, it's brand new, so that's how most learning experiences are. I think it's a decent method.

Conclusion and Implications for Practice

This study is an analysis of TAs perspectives on providing feedback for mathematical modeling activities. Results show specific factors that influence TA's abilities to effectively provide feedback. These findings can be helpful for reforming both current and new programs that implement mathematical modeling or any open-ended problem solving activities.

The current training is the most fundamental component to the success of the TAs. Although MEAs are research-based pedagogical tools that have been heavily researched and developed, there are some miscommunications between the researchers and the practitioners. The TAs commonly complain that students do not understand why they are solving MEAs and some of them do not even understand the learning benefits of MEAs. The learning objectives of MEAs needs to be better communicated in training and the course. It is beneficial to consider implementing a reflective practice that enables the students to try to understand what abilities they gain through a mathematical modeling experience.

STUDENT MISCONCEPTIONS AND GUESSING ON MULTIPLE-CHOICE EXAMS IN MATHEMATICS

Jeffrey J. King
University of Northern Colorado
jeffrey.king@unco.edu

Multiple-choice assessments can be used to provide rapid and large-scale feedback to students in mathematics. In this study, the nature of student guessing on a multiple-choice exam was used to gain insight into student misconceptions of function. Three students in a university-level College Algebra class were asked in individual interviews about their responses on a multiple-choice exam. Interviews were analyzed using three conceptions of function: operational/structural; APOS (action, process, object, schema) Theory; and concept image. Findings include: a disconnect between algorithms, end-goals, and answers; the failure or lack of algorithms leading to guessing; and the use of incomplete- or pseudo-reasoning to inform guesses.

Keywords: Algebra and Algebraic Thinking, Assessment and Evaluation, Cognition

Introduction

"I don't really know how to do the rest of this, but I think I picked B because I knew I had a minus five there and a plus five there, so they would cancel and my answer wouldn't have any fives."

The preceding is a quote from a student explaining her answer on a multiple choice exam question. As it turned out, B was the correct choice, and the student therefore got credit for answering the question, despite the fact that she did not fully understand the mathematical concept. In mathematics, open-ended questions have been generally preferred to multiple-choice to assess higher-cognitive problems, as one generally receives a richer response from an open-ended question. However, several researchers have noted that since open-ended responses require more time, fewer items can be administered (Hamilton, 1998), and scoring by humans on open-ended responses requires a much greater amount of time on the part of the rater.

The purpose of this qualitative study was to examine the nature of student guessing on multiple choice exams in college algebra. The core research question was "What is the nature of student guessing on multiple choice items?" From this core research question, I developed three sub questions: (a) What are the causes of student guessing? (b) At what point does a student decide to guess? (c) When a student decides to guess, what informs the choice he or she makes?

Theoretical Framework

For this study, I focused my analysis on the concept of function, since there is a large body of existing research on students' conceptions of function. Using Sfard's (1992) operational-structural ontological duality, Dubinsky and Harel's (1992) APOS framework, and Vinner and Dreyfus' (1989) ideas of concept image and concept definition, I analyzed students' conceptions of function as 1) pre-function, operational, or structural, 2) pre-function, action, process, or object, and 3) being aware of contradictions or unaware of contradictions. Using these frameworks, I hoped to gain insight into reasons for student guessing.

Methodology

Participants and Setting

The population of this study was students over the age of 18 enrolled in a university-level College Algebra course. Data was collected from confidence questions on the students' second exam. For each problem, participants were asked to give their level of confidence in their answer using a LIKERT scale, with the statement: "I feel confident in my answer to the question" and responses 1-strongly disagree, 2-disagree, 3-neither agree nor disagree, 4-agree and 5-strongly agree. Three students were chosen for interviews, responding to at least one confidence question with 1-strongly disagree. Students were asked to elaborate on their answers to five questions, some differing between interviews, with topics including: 1) identifying the difference quotient, 2) finding the vertex, 3) identifying the graph of a higher order polynomial, 4) identifying the factored form of a higher order polynomial, and 5) identifying the transformations of a basic function.

Data Analysis

Thematic analysis was performed (Patton, 2002) on the transcripts. Causes of guessing, the moment at which the participant decided to guess, and the information used to inform the guess were identified in initial codings. These were identified as Cause, Moment, and Choice, respectively. Each was coded as operational or structural using Sfard's conception and as action-, process-, or object-level using APOS Theory. Codes developed for evoked concept image were: (a) contradictory, unaware; (b) contradictory, aware; (c) non-contradictory, alternative; (d) non-contradictory; and (e) incomplete. Contradictory was defined as the participant using an idea that is logically incompatible with mathematics. Unaware was defined as a participant not checking the veracity of a claim, and so aware was defined as a participant being aware of the veracity of a claim. Alternative was defined as using knowledge that is not incorrect, but would have proven difficult to provide correct answer in an open-ended response. Incomplete was defined as a participant not possessing a rich enough concept image to give an educated answer.

Findings

In most cases, the students attempted either an operation in the operational/structural sense, or an action in the APOS sense. To capture the similarities between these two, I defined an *algorithm* as any process in which students performed algebraic manipulations or identified algebraic expressions. Examples of algorithms included but were not limited to: 1.) factoring quadratics; 2.) completing the square; and 3.) identifying multiplicities. These operations and actions were intended to produce some kind of result, so I defined an *end-goal* to be a concept or object intended to be found at the end of an algorithm or result of identification. Examples of end-goals include but were not limited to: 1.) the x-intercepts when factoring a quadratic; 2.) the vertex when completing the square to re-write the expression in vertex form; and 3.) the multiplicities of given factors of a polynomial function. In this way, the purpose of finding end-goals was to narrow down the choices to a single answer. Using these constructs of algorithm and end-goals leading to answers, I generated the following themes:

Disconnects Between Algorithms, End-goals, and Answers

For these students, there was at times a disconnect between the algorithms they applied to the problems, the end-goals that they were attempting to find, and the actual answers to the problems. For example, one participant, Emma, attempted to solve for the vertex of a parabola by completing the square. Her end-goal, however, was not to get the expression into vertex form,

but rather to find the x-intercepts. Though she arrived at a method to find the vertex in the roundabout fashion of finding the intercepts and finding the point exactly in between them, it was clear that the disconnect between her algorithm and end-goal caused her to rewrite the expression incorrectly and was then forced to guess. For the same problem, a second participant, Zach, attempted to factor the quadratic expression to find the x-intercepts, but this had no relation to the question of finding the vertex.

In opposition to this, another participant, Zoe, generally had clear connections between her algorithms, end-goals, and the answers to the problems. When she attempted the problems, she applied algorithms for which she understood the end-goal, and she knew that the end-goal was appropriate for answering the problem in most cases. This generally led to Zoe not having to guess on most of the problems, but being able to make choices that followed directly from her work.

Absent or Incorrect Algorithms

In many cases, student-guessing was caused by the lack of an algorithm, or applying an inappropriate algorithm to answer a problem. In both Emma's and Zach's cases, they were unable to properly substitute for $f(x+h)$ in a difference quotient problem, Zach lacking an algorithm and Emma using an incorrect algorithm of substituting $f(x)+h$. For a problem where the students were given a polynomial and asked to identify its factored form, both Zach and Zoe were unable to determine an algorithm that they could use to factor. Zoe, in contrast, used a work-around of multiplying each answer to check against the original polynomial, but she clearly did not have the understanding to answer an open-ended version of the question.

When the participants possessed well-defined algorithms, they were generally able to use deductions to arrive at an answer. Zoe was able to work through the difference quotient quite easily, because she possessed an algorithm for substituting in for $f(x+h)$ that was well-defined in her mind. Similarly, Emma was able to clearly explain how she solved for the factored form of a polynomial using synthetic division, providing an explicit description of the algorithm she followed. Even Zach, who did the most guessing out of all three participants, was able to clearly identify the transformations of a function, because he had a well-defined algorithm of identifying constants in the formula.

Algorithm Failure Led To Guessing

Regardless of the correctness or incorrectness of an algorithm, the participants generally did not begin to guess until their algorithm failed. On both the difference quotient and vertex problems, Emma and Zach both ran into difficulties and could not complete their algorithms. Once this occurred, they both guessed on each problem. When Zach multiplied out all the constant terms in the factored polynomial, that particular algorithm did not serve to narrow down his choices, so he guessed at random without choosing another algorithm to attempt the problem.

When algorithms completed, regardless of whether they were correct or not, the participants were able to make informed choices. In a problem asking students to identify the graph of a fourth-degree, factored polynomial, both Zoe and Emma were able to determine that the polynomial was degree 4. Even though both incorrectly stated that the polynomial had to have three turning points instead of at most three turning points, they were both able to narrow down to a single choice, which was the correct answer. When Zoe answered the vertex problem, even though her algorithm for finding the vertex used an incorrect vertex formula, Zoe was still able to make an informed choice based on her work.

Use of Incomplete- and Pseudo-reasoning

When the participants decided to guess, many times their concept image was either

incomplete or contradictory, regardless of whether the participant was aware of it or not. In this context, *incomplete-reasoning* was defined as the use of reasoning that I would consider "not false," but would prove difficult to apply in an open-ended version of the problem. Some examples of incomplete-reasoning included Emma's claims in the difference quotient problem that the constants involved canceled on top and bottom, and therefore the answer should have no constants. When identifying the graph of a polynomial, both Zoe and Emma used their understanding that the graphs other than their answer choice had too many turning points. While this was not false, they would have had difficulty producing the graph from just the equation using only that knowledge.

To capture when the participants possessed a contradictory concept image, I defined *pseudo-reasoning* as the use of reasoning that I would consider contradictory, with no exploration of the veracity of the reasoning. For the difference quotient, Zach claimed that since the difference quotient had an h in the numerator, which was inside $f(x+h)$, and an h in the denominator, they should "cancel." Zach was almost certainly referring to canceling via division of like terms, although this would seemingly disobey several field axioms as well as any understanding of $f(x+h)$, but he did not feel compelled to determine whether his conjecture made sense or not. When identifying the graph of a higher order polynomial, Zach claimed that since the polynomial was degree four, it was like "two quadratics" multiplied together, so the graph should look like two parabolas that were "connected." This statement seemingly indicated a fundamental error in understanding the nature of functions, even though he was able to choose the correct answer from this reasoning.

Conclusions

In this study, I conducted interviews with three College Algebra students to describe the nature of student-guessing on a multiple-choice mathematics exam. Three subquestions arose out of this core question: (a) What are the causes of student guessing?; (b) At what point does a student decide to guess?; and (c) When a student decides to guess, what informs the choice he or she makes? I discerned that the participants had a disconnect between their algorithms, the end-goals of those algorithms, and the problems they were attempting to answer. The most common cause of guessing was the participant's lacking a correct or using an incorrect algorithm. It was the failure of these algorithms that was the impetus for the participants to guess, even if the algorithm was nonsensical. When the participants decided to guess, they relied on either incomplete- or pseudo-reasoning to narrow their choices and arrive at an answer that at least had some semblance of deduction.

These results have implications in both pedagogy and assessment, as the use and effect of multiple-choice examination has rarely been studied in mathematics. Further research is required to fully understand students' use of algorithms and their associated end-goals, and should be integrated with current research on mathematical reasoning.

PRESERVICE TEACHERS' CONCEPTIONS OF IDENTIFYING AND DEFINING THE MATHEMATICAL PRACTICES

Jean S. Lee
University of Indianapolis
jslee@uindy.edu

Sarah A. Roberts
Iowa State University
sroberts@iastate.edu

This study examines preservice teachers' (PSTs') proposed use of the Mathematical Practices in an algebra task. PSTs in the study struggled to understand in their proposed teaching of the task that the quantity of Mathematical Practices did not necessarily translate to quality of instruction. PSTs described the practices in multiple ways – sometimes in line with the descriptions in the standards documents and sometimes not. The findings suggest the need to continue to flesh out the practices and provide PSTs with experiences to understand, define, and implement the Mathematical Practices.

Keywords: Algebra and Algebraic Thinking, Problem Solving, Standards

Purpose of Study

The Common Core State Standards (CCSS-M) Mathematical Practices (2010) provide a framework for how teachers can engage students in mathematical work. While the CCSS-M document spells out in limited detail how teachers and students might enact the Mathematical Practices, preservice teachers (PSTs) may not have a clear vision of what it means to enact them. We had PSTs explore and explicate how they would attend to the Standards for Mathematical Practices (SMPs) in their teaching of the Skyscraper Windows task (adapted):

> A building is 12 stories high and is covered entirely by windows on all four sides. Each floor has 38 windows on it. The cost of washing the windows is $2.00 for each first-floor window, $2.50 for each second-floor window, $3.00 for each third floor window, and so on. How much will it cost to wash the windows of this building? What if the building is 30 stories tall? *n* stories tall? (Driscoll, 1999, pg. 70)

We explore which SMPs PSTs chose for the task, how their vision of the SMPs compares to the CCSS-M document, and how this work might have implications for future work with PSTs. Our research questions are: 1) How do PSTs identify how they might use the SMPs? and 2) How do PSTs' conceptions compare to the intent of the CCSS-M document?

Theoretical Framework

This study uses a situative perspective, in that learning is "situated in physical and social contexts, social in nature, and distributed across persons and tools" (Putnam & Borko, 2000, p. 12). As PSTs considered the SMPs within the context of their future classroom implementation of the task, they drew on interactions, prior experiences, and engagement in various communities of practice (as K-12 students, college students, PSTs, in practicum, etc.). PSTs' interactions with their environments and other people help determine what and how learning takes place.

Methods

Participants

Participants included 15 undergraduate secondary mathematics PSTs from two mathematics methods courses at two universities in the Midwest. Eleven PSTs had been in their first methods course for no more than two weeks during the time of the study; the remainder was in first methods for no more than four weeks. Both groups had not studied the SMPs prior to this time.

Data Collection

PSTs completed the task individually, read the CCSS-M document (2010), and wrote a reflection on how to include the SMPs. The reflection prompts included PSTs drawing on and using examples from their work to explain how to include the SMPs in teaching this task. During class time, PSTs compared their mathematical solutions to the task with their peers and reflected on how their future students could demonstrate the SMPs.

Data Analysis

Qualitative data analysis occurred during and after data collection to focus and shape the study (Glesne, 2011). We focused our analysis on the PSTs written work, focusing specifically on PSTs' responses to how they intended to implement the SMPs in their instruction. We calculated the frequency of each SMP PSTs chose. We then used open coding (Strauss & Corbin, 1990) to analyze PSTs' written reflections and generated themes within each SMP, examining statements for emerging themes across multiple or all SMPs and comparing the PSTs' statements to the CCSS-M document (2010) in order to identify consistencies and inconsistencies across themes.

Findings

The PSTs selected multiple SMPs for the Skyscraper Windows Task. Here we focus on the two SMPs the PSTs identified most often: *Make sense of problems and persevere in solving them,* and *Model with mathematics.*

Make Sense of Problems and Persevere in Solving Them

Eighty-seven percent of PSTs identified *Make sense of problems and persevere in solving them* as a SMP to include in their teaching of the Skyscraper Windows Task. Below we describe the three emerging themes related to PSTs intended implementation of this SMP.

First theme: get students to identify information. Almost half of the PSTs (47%) shared that students need to identify the important given information to solve the problem. A PST commented that a teacher could focus on this SMP through "having the students break down the givens and ask for-s in the problem." Similarly, another PST noted, "You must understand or have a feel for what the question is actually asking you." These statements align with the CCSS-M document (2010): "[Students] analyze givens, constraints, relationships, and goals." The PSTs attention was on supporting students to make sense of the task and the key information therein.

Second theme: Reduce the initial demand of the task. Thirteen percent of PSTs noted that one way to support students in persevering in solving the task would be to scaffold the task by reducing the initial demand of the task. Instead of having students begin with solving for *n* floors, multiple PSTs suggested beginning with fewer floors:

> The best way I can think to help students persevere in solving this problem is to reduce the initial challenge by reducing the floors in the first example. A little success can go a long way in boosting a student's ability to persevere in the fact of adversity.

The CCSS-M document (2010) highlights that students might "consider analogous problems, and try special cases and simpler forms of the original problem in order to gain insight into its solution." It is unclear whether the PST meant the teacher should provide an analogous or simpler problem or if the students should be working on their own to recognize a strategy of

working with a smaller-story building before finding the cost of a 30- or *n-story* building.

Third theme: Initiate at the beginning of the task. Thirteen percent of PSTs noted they would engage students in persevering though the problem as students begin working on it. PSTs focused on what students would need to do once a teacher gave them the problem. One PST commented, “It [the SMP] would be used at the beginning of the task. After the students have had the chance to read the task and work on it for a few minutes.” This comment might align with the CCSS-M statement (2010), “Mathematically proficient students start by explaining to themselves the meaning of a problem and looking for entry points to its solution.”

Comparison to CCSS-M document. The CCSS-M document (2010) states, “Mathematically proficient students can explain correspondences between equations, verbal descriptions, tables, and graphs or draw diagrams of important features and relationships, graph data, and search for regularity or trends.” PSTs proposed specific prompts to move their students’ thinking forward, but the PSTSs did not identify how the prompts would help students make sense and persevere in problem solving. For instance, PSTs might ask their students to: explain the relationship between the floor number and how much it costs to get the windows cleaned; explain which variables you are using in your equation and why; list how you could calculate the price for the first six floors; and/or explain whether your rule works for even and/or odd number of floors, etc. While these statements align with what the CCSS-M document advocates, there is a disconnect between the questions PSTs might ask to move students’ thinking forward and whether the prompts support their students in demonstrating this SMP.

Model with Mathematics

Eighty-seven percent of the PSTs identified that they would include *Model with mathematics* in their teaching of the Skyscraper Windows task. We describe the three emerging themes on this SMP in more depth.

First theme: Represent a situation with an equation, table, or graph. Over a third of the PSTs (34%) commented that their students would use and make “connections between tables and graphs” when they solved the Skyscraper Windows Task. Additionally, one PST noted, “The goal of the entire problem is to come up with a mathematical expression that represents the problem.” Another PST explained that her students would need to move between two representations: “It will help students visually see and understand the relationship between functions and tables—knowing how to use tables and what an equation should look like depending on the degree of the polynomial.” This response particularly aligns with the CCSS-M document (2010) that notes students should “identify important quantities in a practical situation and map their relationships using such tools as diagrams, two-way tables, graphs, flowcharts and formulas.” PSTs focused some of their attention related to this SMP on the representations their students might use in solving the task.

Second theme: Real life context helps bridge connection to mathematics. Over a quarter of the PSTs (27%) reflected that the Skyscraper Task included *Modeling with mathematics,* because the task inherently included a “real life” context. One PST reflected, “This is a real life model, so it teaches students how to work with math in the real world. This will help students work with math in the real world.” Another PST noted, “This problem is a real life type of problem so it is modeling with math in and of itself.” The language in the CCSS-M document (2010) could have motivated these statements: “Mathematically proficient students can apply the mathematics they know to solve problems arising in everyday life, society, and the workplace.” Even though a problem uses a real world context, the context itself does not constitute modeling.

Third theme: Use the “follow me” method. Seven percent of responses documented that

Model with mathematics was an instructional strategy where a teacher does the problem first and students follow the teacher's demonstration. A PST suggested: "I could help my students do this problem by modeling similar problems and pointing out how to find solutions." Such language is not present in the CCSS-M (2010) document.

Comparison to CCSS-M document. A key component missing in all PSTs' reflections for this SMP was that their students should be able to assess the strength of their relationships, logic, and conclusions. Instead, PSTs focused only on using graphs and tables and having a real-life context. In addition, PSTs did not concentrate on their students' ability to "analyze those relationships mathematically to draw conclusions. They routinely interpret their mathematical results in the context of the situation and reflect on whether the results make sense, possibly improving the model if it has not served its purpose" (CCSS-M, 2010).

Discussion & Conclusion

PSTs attempted to explicate how they would include the SMPs in the teaching of the Skyscraper Windows Task. Although the CCSS-M document articulates how students can demonstrate the SMPs, our findings illustrate that PSTs' conceptions of the SMPs do not always align with the CCSS-M document.

PSTs needed to grapple with the fact that the *quantity* of the SMPs in the teaching of a task does not necessarily translate to the *quality* of that instruction. Over a third of the PSTs (33%) stated they would integrate all eight SMPs into teaching this task. While certain tasks can lend themselves to including some mathematical practice more easily than others, many of this study's PSTs seemed to believe that they could enact a SMP based simply on the design of the task: the "CCSS-M mathematical practices sort of fall into place with this problem." Another PST suggested, "I feel as though several of these practices are already embedded in this problem and I don't think a teacher could not use at least a few of these practices simply by presenting the problem." These comments convey that the PSTs felt that SMPs were intrinsic to the Skyscraper Windows task. The PSTs needed to focus their attention instead on how their students might be able to demonstrate behaviors indicative of SMPs within the task implementation. PSTs need opportunities to understand that the SMPs are largely dependent on the teacher, and the teacher needs to provide appropriate scaffolds so students demonstrate them.

PSTs may need multiple opportunities with different contextual activities to better understand the SMPs and how to include them in their instruction. Further discussion with other mathematics educators should focus on continuing to flesh out what the SMPs encompass and working on ways to support PSTs in understanding and implementing them in their classrooms.

MENTAL MATHEMATICS, OPERATIONS ON FUNCTIONS AND GRAPHS

Jérôme Proulx
Université du Québec à Montréal
proulx.jerome@uqam.ca

This study, part of a larger research program on mental mathematics with objects other than numbers, concerns operations on functions in a graphical environment. It aims at characterizing students' mathematical activity in this mental mathematics environment. The data analysis offers understandings of how students solved the various tasks, highlighting three specific approaches engaged with: algebraic/parametric, graphical/geometric, and numerical/graphical.

Keywords: Instructional Activities and Practices, Algebra and Algebraic Thinking, Problem solving

Context of the Study

Diverse studies show the significant impact of mental mathematics practices with numbers on students' problem solving skills (Butlen & Peizard, 1992; Schoen & Zweng, 1986), on the development of their number sense (Heirdsfield & Cooper, 2004), on their paper-and-pencil skills (Butlen & Peizard, *ibid.*) and on their estimation strategies (Heirdsfield & Cooper, *ibid.*; Schoen & Zweng, *ibid.*). For Butlen and Peizard (*ibid.*), the practice of mental calculations can enable students to develop new ways of doing mathematics and solving arithmetic problems that the traditional paper-and-pencil context rarely affords because it is often focused on techniques that are efficient and do not require other action. Overall, there is agreement that the practice of mental mathematics with numbers enriches students' mathematical work about calculations and numbers. This being so, as Rezat (2011) explains, most if not all studies on mental mathematics focus on numbers/arithmetic. This rouses interest in knowing what teaching mental mathematics with mathematical objects other than numbers might contribute to students' mathematical reasoning. In this study, issues of functions, mainly operations in a graph, are investigated.

Theoretical Grounding of the Study: An Enactivist Frame

Recent work in mental mathematics points to the need for better conceptualizing how students develop mental strategies. Threlfall (2002) insists on the organic emergence and contingency of strategies in relation to the tasks *and* the solver (what he understands, prefers, knows, has experienced with, is confident with; see also Butlen & Peizard, 1992; Rezat, 2011). In mathematics education, the enactivist theory of cognition has been concerned with issues of emergence, adaptation and contingency of learners' mathematical activity (c.f. Maturana & Varela, 1992; Varela, Thompson & Rosch, 1991). Therefore, aspects of the theory (in particular, Varela's concept of *problem-posing*) are used to ground this study to make sense of students' mathematical strategies and activity. For Varela (1996), problem-solving implies that problems are already in the world, waiting to be solved, independent of us as knowers. Varela explains, on the contrary, that we pose or specify the problems we encounter through the meanings we make of the world in which we live, which leads us to recognize things in specific ways. We do not choose or take problems as if they were lying out there, independent of our actions, but we bring them forth. The problems we encounter, the questions we ask, are as much a part of us as they are a part of our environment: they emerge from our interaction with/in it. The problems we solve are implicitly relevant for us as we allow them to be problems for us. If one adheres to this perspective, one cannot assume that instructional properties are present in the tasks presented and that these determine solvers' reactions. Reactions to a task do not reside

inside either the solver or the task: they emerge from the solver's *interaction* with the task, through posing the task. Hence, issues addressed in a task are those that resonate with and emerge from students, although triggered by the task offered. Students *transform* tasks, making them their own, generating their own strategies for solving (their) tasks, as adapted responses, locally tailored to it. It is this dynamic orientation toward the development of strategies that guides this study.

Methodological Considerations, Data Collection and Analysis

Classroom activities/tasks were designed with a grade-11 teacher (covering two 75-minutes sessions for each group), in which students had to operate mentally on functions in a graphical environment: they had to solve tasks without paper-and-pencil or any other aid. For each task, (1) a graph was shown on the board and instructions were given orally; (2) students had 20 seconds to think about the solution; (3) at the signal, students had 10 seconds to write their answer (on a blank Cartesian graph) and hold it up to show the teacher; (4) various students were asked to show/explain their answers. For example, a typical task consisted of showing two functions in the same graph and ask students to add/subtract them (see Figure 1).

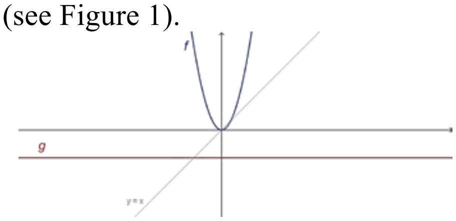

Figure 1: Example of a Graphical Task on Operations on Functions [$f(x) \pm g(x)$]

Tasks were organized in 6 blocks, each composed of 6-10 tasks (consisting of a combination of linear, constant, square-root, rational, step, etc., functions). In block 1, *both* the graph and the algebraic expression of the functions were offered. In block 2, graphs of two functions were given without their algebraic representation. In block 3, students were given the representation of one function and the result of an operation in the same graph. They were instructed to find the function that had been added to or subtracted from the first to obtain the resulting function. Block 4, similar to the second, focused on subtractions. Block 5 differed in that only algebraic expressions of functions were given. These algebraic expressions could not be "directly" computed, like $f(x)=|x|$ or $f(x)=[x]$ with $g(x)=x$ or $g(x)=x^2$. In block 6, students had to add two functions that looked symmetrical in the graph (see e.g. Figure 2 and 4).

Data collection focused on students' strategies, recorded in note form by the PI and a research-assistant. Three types of strategies emerged, which are briefly reported below: algebraic/parametric approach, graphical/geometric approach, graphical/numerical approach.

Findings: Characterization of Strategies

Strategy 1. The Algebraic/Parametric Approach

Even if tasks were proposed in a graphical context, a significant number of students engaged in algebraic-related solving. For tasks where algebraic expressions were not available, students referred to what Duval (1988) calls *significant units* for "reading" the graphical representation of a linear function and offered an interpretation in relation to the algebraic expression. That is, students paid attention to the parameters of the algebraic expression (the *a* and *b* of the linear function $f(x)=ax+b$) to make sense of the graphs and operate. However, again, because the resulting function had to be expressed graphically, they (fluently) explained their answer and strategy algebraically by blending aspects of graphical information. For example, in the following addition task (see Figure 2), where neither function has an algebraic expression attached, students explained that "BOTH FUNCTIONS LOOKED SYMMETRICAL, SO THE 'a' PARAMETER OF EACH LINE WOULD CANCEL OUT, AS WELL AS THE 'b'

AND THUS GIVE x=0”. Students derived algebraic information from the graphs of the functions in order to operate and develop their solution. Even if tasks were offered in a graphical context, students engaged with them algebraically, drawing out algebraic aspects of the functions (expressions, parameters, etc.).

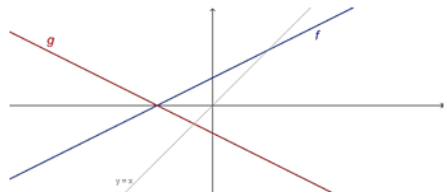

Figure 2: Addition of Function Graphical Task

Strategy 2. The Graphical/Geometric Approach

When facing a function that was not linear (e.g. quadratic, square root, rational, hyperbolic), students assigned a *constantly changing* rate of change/slope to the function they were dealing with. For example, with the addition of a quadratic and a constant function (see Figure 1), the rate of change of the quadratic function was not affected by the addition of a constant function, because a constant function “DID NOT HAD A VARIATION”, hence the slope of the quadratic function “WILL CONTINUE TO VARY IN A CONSTANT WAY”. When students said *constant*, they meant that its appearance was not affected. The resulting function of their addition would have the “SAME RATE OF CHANGE AS THE QUADRATIC FUNCTION” but would simply be “TRANSLATED DOWN” in the graph because the constant function was “NEGATIVE”. Although it is not clear what was meant by this “CONSTANTLY CHANGING” rate of change/slope for nonlinear functions (especially e.g. when they were dealing with $f(x)=1/x$), students developed a way that enabled them to solve tasks and not worry about the variation inherent in the function. In cases where students faced more than one nonlinear function, they began analyzing functions in terms of “parallelism”. For example, in Figure 3 where function g is to be found, some students expressed “EACH FUNCTION WAS PARALLEL TO THE OTHER” and that g had to be a constant function “FOR THE CURVE TO BE TRANSLATED DOWN” and that this constant function was “NEGATIVE FOR BRINGING THE CURVE LOWER”. These students were offering a geometrical interpretation of rate of change/slope, as a property not of the function but of the curve in the graph.

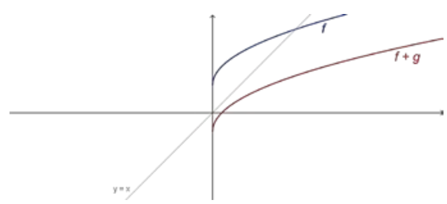

Figure 3: A Task for Which the Parallelism Strategy was Used

Strategy 3. The Graphical/Numerical Approach

A third strategy was to work with specific points in the graphs of functions (related to a pointwise approach, see Even, 1998). Through those points, students obtained exact and approached answers, which they combined to find what the resulting function would look like for *these* points. In Figure 4 students had to find the function resulting from the addition of f and g. In this case, students would fix their attention on specific points: (1) where f crossed the x-axis (x-intercept); (2) where both f and g intersected; (3) where f and g crossed the y-axis (y-intercept); (4) where g crossed the x-axis (x-intercept). For case (1), the operation is an exact calculation, as the addition of the image for f (of length 0) with the one for g results in an image for f+g that is the same as that for g. For case (2), the operation is an approached calculation, as the addition of both image at f and g is the same, and the resulting image is double the value of the intersection point; but a precise location is impossible

without knowing the exact location of the intersecting point in terms of precise length. For case (3), the same approached calculation applies, as both images are added. For case (4), an exact answer is obtained, as in case (1). Here, students mingle both exact and approached calculations to find points for the resulting function.

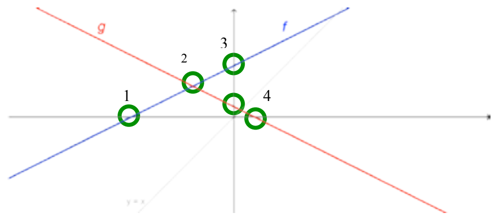

Figure 4: An Addition of Function Task for which Points were Outlined

Discussion of Findings and Final Remarks

These strategies illustrate well students' development *in action* of ways of solving. The strategies reported were enacted on-the-spot, as emergent reactions tailored to the tasks; determined by students' mathematical experience (their past, preferences, habits, etc.) and influenced by tasks (one does not react in the same way to two square-root functions as one does with two linear intersecting ones). Through their entry into the tasks, students *posed* the tasks offered to them, they posed their own problems, making them algebraic, geometric, procedural, etc. Their posing/solving of the tasks generated strategies for finding the resulting functions. Thus an algebraic reading of functions produced an algebraic approach; a graphical reading produced a graphical approach; a numerical/pointwise reading produced a numerical pointwise approach. Through this, students illustrated significant solving capacities, as they were fluent in linking algebraic (symbolic expression), numerical (coordinate points in x or y) and graphical aspects of functions. This seems to contrast with what we know from other studies, as students are frequently reported as experiencing difficulties of many kinds when linking graphs of functions with other representations (e.g. Even, 1998; Hitt, 1998). This underlines some potential of this mental mathematics activity for learning about functions, as it made emerge numerous (and even alternative) ways of conceiving/operating on them. More research is still needed, but this shows important promise to enrich students' experiences with functions.

PERSISTENCE AND SELF-EFFICACY IN PROVING

Annie Selden
New Mexico State University
aselden@math.nmsu.edu

John Selden
New Mexico State University
js9484@usit.net

We first discuss our perspective on, and three useful actions in, proof constructions that depend on persistence. Persistence is often important for successful proving because it helps one "explore," including making arguments in directions of unknown value, until one ultimately makes progress. Persistence can be supported by a sense of self-efficacy, which is "a person's belief in his or her ability to succeed in a particular situation" (Bandura, 1995). We then examine the actions of one mathematician when proving a theorem that had previously been given to mid-level undergraduates in a transition-to-proof course. We end with some teaching implications.

Keywords: Advanced Mathematical Thinking, Reasoning and Proof, Beliefs

Introduction

In this paper we first discuss our perspective on proof construction. Then we point out three aspects of proof construction that appear to be difficult to teach. We suggest that the difficulty arises partly from a need for students to have a kind of persistence that depends on students having a feeling of self-efficacy. We next discuss self-efficacy and illustrate the way that self-efficacy and persistence are valuable by examining one mathematician's actual proof construction and note his remarkable persistence. We end with some teaching implications.

An Action Perspective

While we view proofs as texts written in a certain genre (Selden & Selden, in press), we view constructing a proof as a sequence of actions (Selden, McKee, & Selden, 2010). Some of these are physical, such as writing a line of the proof, and some are mental, such as focusing on the conclusion or "unpacking" its meaning. Such actions are taken in response to certain kinds of (autonomously recognized) situations in a partly constructed proof. With practice, the links between some repeatedly occurring proving situations and an individual's resultant actions will become automated, thus reducing the burden on his or her working memory in future proof construction. Many such actions are not recorded in the final written proof.

Three useful actions in proof construction

In several iterations of teaching a second-year university transition-to-proof course in a modified Moore Method way (Mahavier,1999), we have observed proof construction situations calling for one of the following three actions: (a) *Exploring.* In constructing a proof, one may understand both what is to be proved and what is available to use without having any idea of how to proceed. In such situations, one might reasonably try to prove any plausible result, including results of unknown value. However, few students show any evidence of doing this, perhaps lacking confidence in their own ability to use whatever new they might prove. (b) *Reworking an argument in the case of a suspected error or wrong direction.* In constructing a proof, one may come to suspect one has made an error or is arguing in an unhelpful direction. An appropriate response would be to rework part of the argument. However, many students appear to be reluctant to do this. (c) *Validating a completed proof.* Upon completing a proof, one should read

it over carefully for correctness from the top down, checking whether each line follows from what has been said above. Few students appear to do this.

While some student difficulties may depend on a wrong belief about mathematics, on inadequate or incorrect logic, or on a misinterpretation of a definition, failing to take the above three actions in proof construction are not about mathematics per se, but rather about habitually acting appropriately in particular situations. Taking such actions is similar to what Mason and Spence (1999) have called "knowing-to-act in the moment."

Self-efficacy

Self-efficacy is "a person's belief in his or her ability to succeed in a particular situation." "The most effective way of developing a strong sense of self-efficacy is through mastery experiences." Further, performing a task successfully strengthens one's sense of self-efficacy. Short of achieving such success, "Seeing people similar to oneself succeed by sustained effort raises observers' beliefs that they too possess the capabilities to master comparable activities [in order] to succeed." (Bandura, 1994, 1995).

According to Bandura (1994), individuals with a strong sense of self-efficacy: (a) view challenging problems as tasks to be mastered; (b) develop deeper interest in the activities in which they participate; (c) form a stronger sense of commitment to their interests and activities; and (d) recover quickly from setbacks and disappointments. In contrast, people with a weak sense of self-efficacy: (a) avoid challenging tasks; (b) believe that difficult tasks and situations are beyond their capabilities; (c) focus on personal failings and negative outcomes; and (d) quickly lose confidence in personal abilities.

Bandura's ideas "ring true" with our past experiences as mathematicians teaching courses by the Moore Method. Classical Moore Method (advanced undergraduate or graduate) courses are taught from a brief set of notes consisting of definitions, a few requests for examples, statements of major results, and those lesser results needed to prove the major ones. In class meetings, the professor invites individual students to present their original proofs and then briefly comments on errors. Once students are able to successfully prove the first few theorems, they often progress very rapidly in their proving ability, even without apparent explicit teaching, and even when subsequent proofs are more complex. Why should this be? We conjectured then, and also now, that students obtained a sense of self-efficacy from having proved the first few theorems successfully, and this helped them persist in explorations needed to prove subsequent theorems.

Background for One Mathematician's Proof

Below we describe one mathematician's proof of *Theorem 20: If S is a commutative semigroup with no proper ideals, then S is a group.* The needed background information is very small, and we provide it here. A *semigroup* is a nonempty set S with an associative binary operation that we will write multiplicatively as xy for elements x and y of S. *Associativity* means that for all elements x, y, and z of S, $(xy)z = x(yz)$. S is *commutative* means that for all elements x and y of S, $xy = yx$. If A and B are subsets of S, AB is the set of elements ab, where a and b are elements of A and B respectively. In this setting, a nonempty subset I of S is an *ideal* of S provided SI is a subset of I. Such an ideal is called *proper* in S provided it is not all of S. In this commutative setting, S is a *group* if it has two additional properties. First, there must be an *identity* element e of S so that for any element s of S, $es = s$. Second, given any element s of S there must be an *inverse* element s' of S so that $s's = e$.

In proving the above theorem, it is easy to see that if I is an ideal of S, one can conclude I is not proper, that is, $I = S$. What is not so easy is trying to construct an ideal that "looks" different

from *S*, and what that might have to do with producing an identity element *e* of S and inverses, in order to prove that *S* is a group. Since there is nothing else to work on, one must persist in trying to find an ideal of *S* without any idea of whether, or how, that might be helpful. It turns out that some students rather quickly think that if *s* is any element of *S* then $S\{s\}$ (also written *Ss*) might be an ideal of *S*, and hence equal to *S*. Once the idea has been articulated, it is not so hard to prove that *Ss* is an ideal. But how might the set equation $Ss = S$ help in proving that *S* is a group? However, if *t* is also an element of *S*, the above set equation means that there must be an element *x* of *S* so that $xs = t$. That is, the equation $xs = t$ can always be solved for *x*. It turns out that one can use the solvability of this equation in several ways to collect information which, for many students, is of unknown utility. Nevertheless this information, once collected, can be organized to show the existence of an identity element and inverses in *S*. To do this requires both persistence and a willingness to obtain whatever results, in the form of equations, that one can without knowing whether those results will ultimately be helpful.

One Mathematician's Proof Construction

Savic (2012) investigated mathematics professors' naturalistic proving using a set of notes that had previously been used by us with undergraduate students. Several of the mathematicians acknowledged getting "stuck" on *Theorem 20: If S is a commutative semigroup with no proper ideals, then S is a group*. However, none gave up, as most students might, but persisted.

Dr. G's construction of a proof of Theorem 20

Below we describe much of the work of Dr. G in attempting to prove Theorem 20, which he eventually did successfully. Our description is a synopsis of Dr. G's transcript. (Savic, 2012)

As seen below, Dr. G took a remarkably meandering path as he explored how to prove Theorem 20. His various "twists and turns" are indicated in bold typeface. Dr. G started at 7:02 a.m. by considering the statement of Theorem 20, but decided to **think about it** and have breakfast. At 8:07 a.m., he returned from a walk and **realized that gS** (where g is an element of *S*) **is an ideal**, so $gS = S$. He then **thought about inverses** and **struckthrough his entire previous argument**. At 8:09 a.m., he **noted that he needed an identity element** which is not given. At 9:44 a.m., he became suspicious that **Theorem 20 might not be true**, but noted that he had few examples which might show that.

At 9:48 a.m., Dr. G started **"tossing around" the idea** that a [commutative] semigroup with no proper ideals must have an identity, in which case, he could show it is a group. However, he didn't see why *S* should have an identity. He **began to think that translating by a fixed element** would move every element, which would mean there was no identity. Consequently, he **then began to look for a counterexample**. By 9:50 a.m. he neither saw how to prove Theorem 20 nor how to find a counterexample.

He then looked ahead to Question 22, which has three parts that ask whether certain semigroups are isomorphic. He **saw how to answer that and then looked at** *Theorem 21: A minimal idea of a commutative semigroup is a group.* He thought that he could probably prove that, so **he went back to Theorem 20**. By 9:51 a.m. Dr. G **recalled that he had earlier rejected Theorems 3, 9, and 12** of the notes and also did not believe that there are unique minimal ideals. By 9:53 a.m., he recalled that he had not been told any of the theorems were false and **looked at the non-negative integers** under multiplication. He saw that $\{0\}$ is a minimal ideal and noted that the non-negative integers under multiplication do not form a group.

At 9:54 a.m., he **started actually answering Question 22**. By 9:58 a.m., he had answered its three parts correctly. At 9:59 a.m. Dr. G. **took a break to think about Theorem 20** and at 10:08 a.m. he again attempted a proof of it. This time **he saw that for $a \in S$, there is $e \in S$ so that $ae =$**

a and saw that e is "acting like …a right identity on a. Now why does it have to act that way on [an arbitrary] b?" By 10:12 a.m. **he found e' so that $be' = b$**, but that didn't help since he couldn't show that $e = e'$. Then at 10:13 a.m. he **saw that there is an f so that $b = af$**, and then by 10:14 a.m., he **saw that $be = afe = aef = af = b$**. At 10:15 a.m., he **saw that e is the identity** element. By 10:18 a.m., he had **used a similar technique to show S has inverses** and is thus a group.

Perhaps the most important thing about the above description of Dr. G's work is what is *not* there. There is no evidence that Dr. G thought there was anything wrong with having gone in all of those unhelpful directions or with having thought that some theorems were false, that he later discovered were true. What seemed to matter to him was the generation of ideas. If those ideas resulted in errors, one fixed them and learned from them. He exhibited remarkable persistence and a willingness to try argument directions that he clearly didn't know ahead of time would be helpful, and he altered directions when the need arose.

Teaching Implications

It seems to us that in order to take proving actions that require persistence and exploration, a student is likely to need to believe that he or she can personally benefit from his or her persistence or exploration. That calls for a self-efficacy belief, which in turn calls for, perhaps numerous, successes in similar actions.

In order to maximize students' opportunities to experience successes in various aspects of proving, it would be good to have students constructing their own proofs as early and often as possible. There is an aspect of proving that is not usually explicitly taught, but that could be very helpful in facilitating students' early successes. It is based on the relationship between the logical structure of the theorem being proved, the structure of a proof, and the theorems and definitions used in constructing the proof. Selden and Selden (1995) have referred to this as a *proof framework*. In constructing a proof framework, one writes as much as possible of a proof before attempting to generate the ideas needed to complete it. One writes the hypotheses first, leaves a blank space for the body of the argument, and then writes the conclusion. Typically one next "unpacks" the meaning of the conclusion, which allows one to write more of the beginning and end of the proof. One proceeds as far as possible in this way. After a framework has been constructed, a student can then try to generate ideas needed to complete the middle of a proof.

CULTIVATING LEARNING OPPORTUNITIES FOR JUSTIFICATION IN AN URBAN MIDDLE SCHOOL MATHEMATICS CLASSROOM

Sarah Kate Selling
Stanford University
sselling@stanford.edu

This study explores how whole class discussions across the first four weeks of school provided learning opportunities for justification to students who have little prior experience in this practice. Seven class discussions were analyzed in a 6th grade math class in an urban public school. Preliminary analyses indicate that even brief class discussions offered rich learning opportunities for (1) acceptable modes of justification in the classroom community, (2) what needs to be justified, and (3) the mathematical language for communicating justifications. These findings demonstrate how teachers might cultivate opportunities for justification for all students.

Keywords: Reasoning and Proof, Classroom Discourse, Instructional Activities and Practices

Justification is central to *doing* and *learning* mathematics (Ball, Hoyles, Jahnke, & Movshovitz-Hadar, 2002). This is reflected in the Common Core Standards for Mathematical Practice (2010) that call for students to "construct viable arguments and critique the reasoning of others" across all grade levels. However, a wide range of studies have documented students' challenges with justification (e.g. Balacheff, 1988; Knuth, Choppin, & Bieda, 2009), which may reflect that many US mathematics classrooms offer few opportunities to engage in justification (Stigler & Hiebert, 2009). A major challenge currently facing teachers is how to help *all* students engage in this central mathematical practice when their students may have had few prior learning opportunities to do so. This study explores how a teacher might cultivate learning opportunities for justification in the first weeks of school with students inexperienced in this practice.

Ball and Bass (2003) argue that justification in classrooms rests on two foundations. The first is the *base of public knowledge*. This includes the "taken-as-shared" (Yackel & Cobb, 1996) concepts, procedures, defined terms, and methods of verifying mathematical claims that serve as a starting point for constructing arguments. The notion of taken-as-shared does not imply that all members of the community hold this knowledge; rather, it refers to what is accepted as true without justification within a particular community. The second foundation is *mathematical language*, which they take to mean the symbols, terms, representations, and rules that guide their use in how claims are formed and justified. This includes the central role of definitions in constructing justifications. This distinction between two aspects of justification is similar to Stylianides's (2007) conceptualization of a mathematical argument in which he differentiates between the set of accepted statements, the mode of argumentation and the mode of argumentation representation. These perspectives are helpful in unpacking the types of arguments that students make, as well as what aspects of justification might need to be deliberately cultivated. Ball and Bass cite three aspects of classroom practice that are important for teaching justification, including designing and using tasks that afford opportunities to justify, making records of mathematical knowledge, and making ideas public. Whole class discussions are one classroom structure in which mathematical ideas can be made public. Many scholars have demonstrated how these discussions can support collaborative reasoning in mathematics (e.g. Staples, 2007). Through the close analysis of one middle school classroom during the first four weeks of school, this study addresses the following question: How might a teacher cultivate

justification through whole class discussions in a middle school mathematics classroom?

Methods

The data for this study is drawn from a larger project investigating the teaching and learning of justification in an urban secondary school in an under-resourced community in Northern California. The analyses for this study draw on classroom data from the first four weeks of school in one 6th grade classroom. The focal teacher, Mr. Carrera, was selected based on his commitment to fostering collaborative mathematical inquiry. He identified justification as one of his central goals for *all* students. This 6th grade class was a particularly rich site for exploring the cultivation of justification since the students were all new to the school and Mr. Carrera's teaching approach. Semi-structured interviews established that students' prior experiences in math were typical of many US students (Stigler & Hiebert, 2009): the mathematical authority lay with the teacher and the students' role was to pay attention and practice. There were 26 students in the class (21 Latino/a, 3 Asian-American, 2 African-American). All names are pseudonyms.

These analyses draw on video records of whole class mathematical discussions that spanned the first four weeks of school. These discussions ranged between 12 and 40 minutes long. Sometimes they discussed different solutions to homework problems. Other times the discussions occurred after a warm-up task or after extended work on a more complex task. The analysis of the transcripts of these discussions took place in three phases. First, I identified all episodes of students' attempts to justify a mathematical claim regardless of validity. Since justifications were at times co-constructed by multiple students and even the teacher, each episode was defined as starting with the initial student claim and ending when the teacher and class accepted the emergent justification and the focus of the talk shifted. Second, I coded each episode of attempted justification for whether the teacher (or students) prompted, questioned, praised, critiqued, or otherwise commented on the justification. Third, I coded these instructional moves for if and how they addressed the different aspects of justification described by Ball and Bass (2003). For example, when Juan shared his ideas about 3^2, saying "Three times three", Mr. Carrera asked, "Would you say how you decided?" Juan responded "Because the two here says to write the three two times." Mr. Carrera accepted this, saying "Very good. Exactly." This episode was coded as mode of argumentation, since Mr. Carrera prompted him to say "how you decided" and then accepted a justification that reasoned from a definition.

Emergent Findings

Preliminary analyses suggest that the class discussions provided learning opportunities for justification around the publically accepted knowledge base and the language of justification.

Cultivating Justifications that Make Sense

On the second day of school, the class discussed the following homework problem: *Jackie has 12 square tiles. What are all the different rectangles he could make using his tiles?* Right before this episode, Alonzo drew a 3×4 rectangle and justified this claim through counting by threes. Then Mr. Carrera asked Javier, who used a multiplication strategy for a 2×6 rectangle, how he would approach this. Javier drew three dots above and four to the right of the rectangle.

> *Javier:* 3 times 4. Equals 12. Is the other way to see how many squares there are inside.
> *Teacher:* Does someone have a question for Javier? Javier, why do you multiply? Cause heard Alonzo counting by threes, pointing to them so that made sense to me, but why do you multiply?

Here Mr. Carrera communicates that Javier's statement *that* he multiplied is not an acceptable justification; instead, he needs to justify *why* he multiplied. Furthermore, Mr. Carrera explicitly

communicates his standard for justification when he says "so that made sense to me" about Alonzo's counting by threes. For Mr. Carrera, justifications should make sense. Javier continues.

Javier: It-it could be a faster way.

Teacher: You know why multiplying works though? Let's get some other ideas. Tanisha, do you know why multiplying works?

Tanisha: It works because on the top there are three dots and on the side there are four dots. And basically you just multiply them and get twelve.

Teacher: But why multiply?

Tanisha: Because it's faster.

Teacher: That's for sure, right? If you're good at your times table in your head. But why does multiplying work?

Leo: Cause it equals the number that you multiply.

Teacher: It does give you the right answer, that's for sure. [laughter] Why?

Mr. Carrera does not accept the justification that it's faster or yields the correct answer. Finally, Jorge contributes, "Cause each row's a group. There's three in a group. Three – there's four rows, so there's four groups of three". Mr. Carrera asks him elaborate.

Jorge: Each row is like this. [circles the top row of three squares]. Is a group of three. And there – there are four rows. There's the three-four rows of three. So its – right here is the three of these three. And the four rows are this four. Multiply it because it's four groups of three. Equals twelve.

Teacher: Three groups of four. That's really clear for me.

In accepting this justification, based in the meaning of multiplication, Mr. Carrera offers a learning opportunity for acceptable *modes* of verification as well as *what* needs to be justified.

Cultivating Language for Justification

The discussions also offered learning opportunities for the language of justification. On day three, the class discussed: *What does 2^3 mean?* Some thought it meant 2×3=6; others argued for 2×2×2=8. After several minutes of debate, Mr. Carrera steps in.

Teacher: How do you know? Like how can you tell? Tanisha, you were the original one to say that this one [indicating 2×2×2=8] was right, right? So how do you know?

Tanisha: You know because if you try to do the math, and you're actually writing it up there it would be 8.

Teacher: And you're saying "do the math" means do this? [points to the 2×2×2=8]

Tanisha: Yeah

Teacher: Uh-huh. Not do 2×3 [points to the 2×3]. Yeah. So, does anyone know what this three is called? [points to the 3 in the 2^3]

Mr. Carrera recognizes that the debate about 2^3 cannot be resolved without the definition of an exponent. He then elicits the definition, which allows them to resolve the debate.

Mr. Carrera also frequently emphasized what he calls "technical writing", such as color coding to show connections and labeling diagrams. For example, on day four, Leo presented his ideas for finding the area of 12×9 rectangle. He wrote down 12×9 = 108. Mr. Carrera asked Leo to record "where's the 9 and the 12?" Leo did not seem to know what Mr. Carrera wanted. So Mr. Carrera asked: "Where's the 9 first of all?" Leo used his marker to draw lines that delineated columns of 9 blocks. Mr. Carrera then suggested that he label the top with the 12 and the side with 9. Leo still did not seem to know what to do. Finally, Mr. Carrera used his laser pointer to show exactly where to write the 12 and 9. This episode is a case of providing access to the *mathematical language* necessary to communicate justifications. For statements like 12×9 = 108

to have meaning and be accepted as justifications, the students needed to communicate why 12 and 9. Tools like labeling provided the language to communicate meaning.

Implications and Directions for Future Research

Although these preliminary analyses draw on only a subset of the data, the emerging findings suggest that these whole class discussions were able to offer multiple learning opportunities for justification that ranged from what makes an acceptable justification to the role of definitions and tools for communicating and representing justifications (Ball & Bass, 2003; Stylianides, 2007). Furthermore, these learning opportunities emerged out of tasks that were not designed to elicit general statements and justifications of them. The task of explaining the meaning of 2^3 was not framed as a problem about a general statement or proof; however, the way the teacher enacted the task provided opportunities for students to explore the role of definitions in constructing arguments, thereby increasing the cognitive demand of the task (Stein, Grover & Henningsen, 1996). The fact that the learning opportunities for justification highlighted above were cultivated within relatively short whole class discussions of homework problems is promising. For teachers who may feel less confident in implementing proof-related tasks, these smaller discussions of homework problems might provide a scaffold to begin cultivating opportunities for justification.

Further analyses will explore (1) how these learning opportunities for justification are cultivated and coordinated across the first four weeks of school, (2) how these learning opportunities support students' justifications in discussions and in written work, and (3) how students' engagement in justification looks different at the end of the school year. These analyses will have the potential to inform how teachers can cultivate learning opportunities justification for all students. It will also inform what learning opportunities students might need when they arrive with little prior experience in constructing mathematical arguments.

The Common Core State Standards for Mathematics contains both mathematical content and practices for grades K-12. Many researchers focus on the content, but overlook how the practices are embedded within tasks. Each practice includes a brief description that people interpret multiple ways. This study conceptualizes the practices and uses the framework to code two textbook series on bivariate data tasks to determine if students are exposed to the mathematical practices within the textbooks. Initial results indicate that the tasks provide opportunities for students to attend to precision but not to look for and express regularity in repeated reasoning.

Keywords: Curriculum analysis, Data Analysis and Statistics

Purposes of the Study

The Common Core State Standards for Mathematics (CCSSM) was released in 2010 followed by adoption in 45 states and five territories in the U.S. The CCSSM has the potential to shift the landscape of education in the U.S. particularly with the change of content and sequence (Heck, Weiss, & Pasley, 2011). Most discussions concerning the CCSSM have focused on the content standards (e.g., Conley, Drummond, de Gonzalez, Rooseboom, & Stout, 2011; Schmidt & Houang, 2012). However, one important issue related to the CCSSM – the eight mathematical practices (SMPs), has been overlooked. Some researchers and practitioners have sought to elaborate the practices and provided scenarios to illustrate them (e.g., Koestler et al., 2013). However, there have not been any systematic frameworks to code for the SMPs in curriculum materials and no formal research about that work. In this study, we describe how we conceptualize the practices in curriculum materials and provide our initial results about empirical work using examples from one high school textbook series for the content related to bivariate data.

Perspectives and Coding Scheme

In this study, we look at the nature of tasks found in curriculum materials. That is, we seek to determine if the tasks offer the potential for students to utilize the practices. Admittedly, the tasks might offer potential for students to access the practices, but the practices might not be implemented in the same way in each task (Stein & Lane, 1996). Within this study, we highlight the characteristics of tasks that provide the opportunity for students to implement the practices. The performance expectation framework developed in the TIMSS study (Schmidt et al., 1997) was used to provide examples of tasks that offer the opportunities to look for the eight practices. Following is a summary of the coding scheme for SMPs.

1. Make sense and persevere in solving problems (MP1).

Persevering in solving problems is only observed in practice, not in the task itself. Therefore, the framework focuses on the former component. Particularly, we look to determine if the task requires students to formulate and clarify problems and situations such as to: (a) construct a verbal or symbolic statement or a question in which a mathematical problem goal can be specified, (b) design an appropriate statistical experiment to solve a stated problem or to specify the data and range of data needed.

2. Reason abstractly and quantitatively (MP2).

We consider if the task provides opportunities for students to: (a) make sense of quantities (not merely numbers), (b) reason about the relationship between two quantities, and (c) reason abstractly with symbols and formulas.

3. Construct viable arguments and critique the reasoning of others (MP3).

We consider if the task provides opportunities for students to argue or critique others' arguments. Particularly, we look for performance expectations from the task that ask students to: (a) verify the computational correctness of a solution, or justify a step in the solution, (b) identify information relevant to verify or disprove a conjecture, (c) argue the truth of a conjecture or construct a plausible argument, (d) identify a contradiction (something that is never true), (e) critique a written or spoken mathematical idea, solution, result, or method for solving a problem and the efficiency of the method or similarly critique an algorithm and its efficiency.

4. Model with mathematics (MP4).

We consider if the tasks ask students to: (a) construct a verbal or symbolic statement of a real world or other situations, (b) simplify a real world or other problem situation by selecting aspects and relationships to be captured in a representation modeling the situation, (c) select or construct a mathematical representation of a problem (real-world or other problem situation plus a related question/goal), and (d) develop notations or terminologies to record actions and results of real-world or other mathematizable situations.

5. Use appropriate tools strategically (MP5).

We examine if the task mentions something about the selection of tools used to solve the task or if the task inherently requires students to use a technological tool, but not merely for calculation. In this situation, the technological tool is used to deepen understanding.

6. Attend to precision (MP6).

We determine if the tasks ask students to: calculate, measure, or use specialized terms and symbols. Particularly, performance expectations from the task might ask the student to: (a) use equipment to measure, (b) compute/calculate with or without instruments, (c) graph with scale with or without technology/device, (d) collect data by surveys, samples, measurements, etc., (e) develop or select, using notations, terminologies to record actions and results in dealing with real-world or other mathematizable situations, and (f) describe the characteristics of a formal algorithm or solution procedure.

7. Look for and make use of structure (MP7).

We consider if the task provides opportunities for students to look for a structure such as: (a) fit a curve of given type to a set of data (only if students are not told what kind of curve to fit), (b) classify mathematical objects by implicit criteria (e.g., geometric shapes), (c) predict a number, pattern, outcome, etc., that will result from an operation, procedure or experiment before it is actually performed.

8. Look for and express regularity in repeated reasoning (MP8).

We examine if the task offers students opportunities to abstract from a series of similar situations, a general technique, strategy, or algorithm to use in a class of problems. In particular,

we look to see if some of the performance expectations of the task ask students to: (a) describe the effect of a change in a situation (e.g., the effect on its graph of changing a parameter), (b) develop a formal algorithm for computation or a formal solution procedure for problems of a specified class or type, (c) identify a class of problems for which a formal solution procedure is appropriate, (d) generalize the solution, the strategy, or the algorithm of a specific problem, and (e) abstract the common elements from multiple related situations.

Methods

We examined coding schemes and specific examples from the performance expectation framework of the TIMSS study (Schmidt et al., 1997) and adapted the scheme to fit in the context of bivariate data. In particular, we highlighted the performance expectations providing potential for students to access the practices. We then used the framework to code an investigation from the teacher's edition of the *Core-Plus Mathematics* (CPMP) (Hirsch, Fey, Hart, Schoen, Watkins, Ritsema, et al., 2008) to determine if the practices appeared in the set of tasks and revised the coding scheme. In another round, we independently coded the practices for all the tasks related to bivariate data from three teacher's editions: CPMP series (published by Glencoe McGrawHill, 2008, 2009, 2010), The University of Chicago School Mathematics Project (published by Wright Group McGrawHill, 2008, 2009, 2010) and Holt McDougal Larson (HML) series (published by Holt McDougal, 2012). For reliability, pairwise agreements for all eight practices were more than 70%.

Results

Table 1 summarizes the percentages of tasks that address the mathematical practices across the three series. For the set of bivariate data tasks, the percentages vary by series and by practices. CPMP offers the most tasks attending to the mathematical practices, followed by UCSMP and HLM series. Most of the tasks offered students the potential to *model with mathematics* (MP4) and *attend to precision* (MP6) with the focus on computation and calculation. In contrast, very few tasks offer expectation for students to access *make sense and persevere in solving problems* (MP1) and *look for and express regularity in repeated reasoning* (MP8).

Table 1: Percentages of Tasks that Address the Mathematical Practices

	MP1	MP2	MP3	MP4	MP5	MP6	MP7	MP8
HML (N=122)	3.3	57.4	54.1	76.2	37.7	81.1	12.3	0
UCSMP (N=214)	5.1	76.2	43	86.9	52.8	84.6	36	1.9
CPMP (N=246)	10.6	82.4	83.3	89	44.1	87.8	55.9	7.8

Following is the coding of a task taken from CPMP series.

Make a model bungee jump by attaching a weight to an elastic cord or to a chain of rubber bands.

a. Use your model to collect test data about bungee cord stretch for at least five weights. Record the data in a table and display it as a *scatterplot* on a graph.

b. Use the pattern in your experimental data to predict length of the stretched bungee cord for weights different from those already tested. Then test the accuracy of your predictions.

c. Compare your results to those of others doing the same experiment. What might explain any differences in results? (Hirsch et al., 2008, p. 5)

When solving this task, students have chances to (2a) make sense of quantities such as weight and length and (2b) reason about the relationship between the two quantities; (3b) identify information relevant to verify or disprove a conjecture, (c) argue the truth of a conjecture or construct a plausible argument, and (e) critique a written solution, result; (4b) simplify a real world situation by selecting aspects and relationships to be captured in a representation modeling the situation, (4c) select or construct a mathematical representation of a problem (in this case, a graph); (6a) use equipment to measure, (6c) graph with scale with or without technology/device, (6d) collect data by surveys, samples, measurements, etc.; and (7c) predict a number, pattern, outcome, etc., that will result from an operation, procedure or experiment before it is actually performed.

Discussion

The framework for coding mathematical practices shows to be applicable to code for bivariate data or statistical tasks. The tasks' low presence of *look for and express regularity in repeated reasoning* within tasks is significant because educators may need to modify the tasks if they want to address the mathematical practice. It is conceivable that the variation across textbooks illustrates curriculum developers' different interpretation of how to embed the mathematical practices. In addition, the framework clarifies and operationalizes how the written curriculum embeds the SMPs. Further research needs to examine the framework in different domains. Furthermore, when coding tasks from the textbooks, we look specifically at the teacher's edition to see how the authors expect the tasks to be implemented. This might be different from the tasks as implemented in classroom. Hence, future research needs to develop frameworks for coding tasks in implemented phase.

THE ROLE OF PRIOR KNOWLEDGE IN ANALOGICAL REASONING ABOUT THE FORMAL DEFINITION OF A LIMIT

Aditya P. Adiredja
University of California, Berkeley
aditya@berkeley.edu

Research has documented that the formal definition is a roadblock for mathematics students. Studies suggest that students' understanding of a crucial relationship, called the *temporal order* of two variables, ε and δ within the formal definition warrants further investigation (Davis & Vinner, 1986). In the definition, ε comes first before δ, and in instruction δ is often said to depend on ε. This case study is part of a larger study investigating the role of prior knowledge in calculus students' understanding of the formal definition. The larger study argues that relevant intuitive knowledge resides in everyday understanding of quality control. Thus in the individual interview, students engaged with an instructional analogy called the Pancake Story, in which the idea of quality control is illustrated in producing pancakes within specified parameters.

This study explores how one student, DR used the Pancake Story as a resource to revise her claim that ε depended on δ. The study focuses on the process that prior knowledge gets incorporated into, refined and/or elaborated to become a new conception (Smith et al., 1993), specifically ways that prior knowledge interacted with the normative resources from the story. DR revised her claim to δ depending on ε after the story. She attended to normative ideas from the story, but they contradicted her prior knowledge. Her explanation of the confusion illuminates how she ultimately aligned her prior knowledge with the normative resources.

DR: I was looking at it like the $\underline{f(x) \text{ depends on the } x}$ and that's how I was saying that epsilon depends on delta because epsilon is related to the $f(x)$ or whatever. But that's just saying the error of the L and the $f(x)$, depends on the a and x. But that's *not* to say that epsilon depends on delta. So, I think that delta depends on epsilon now. Just cus if it's given like this [*the story*] and you're trying to aim at getting within a certain error bound, then you're gonna try to manipulate your entries or whatever to be within a certain error bound.

Interviewer: Ok. Alright. So you changed your mind it seems? Um, so how did that happen? Why did you change your mind?

DR: Because I was given an epsilon and that's kinda the main goal. The main goal is to get the pancake, like that's the main goal. And they gave me a constraint. /…/ And then delta or they didn't give me an error bound for the batter or for the a or x, they didn't give me an error bound. But I know I want to make it small so that it's within the like error bound /…/, or the epsilon. So then I would kinda base my delta on what was epsilon.

Once DR found a way to align her prior knowledge with the normative knowledge resources from the story, DR could prioritize the normative resources. The resource of $f(x)$ depends on x was repurposed to inform the dependence between the errors ($|f(x)\text{-}L|$ and $|x\text{-}a|$), not the error bounds (ε and δ). Earlier DR also differentiated errors from error bounds. The main goal of getting the pancake within the error bound and the fact that epsilon was given but not delta, from the story were then used to conclude that DR had to "base my delta on what was epsilon."

FRACTIONS SCHEMES AND WHOLE NUMBER UNITS COORDINATION

Steven Boyce
Virginia Tech
sboyce@vt.edu

Anderson Norton
Virginia Tech
norton3@vt.edu

Keywords: Number Concepts and Operations, Rational Numbers, Learning Theories

Introduction/Purpose

Across mathematics content domains, the construct of *units coordination* has emerged as an important factor in both learning and teaching. Units coordination is the forming of a structure that allows one to retain, when *assimilating* a *quantity*, the relationships between intermediate *unitizing* activities. For example, a person coordinating three levels of units can immediately and simultaneously think of 15 as both: (a) a unit of five threes, each a unit of three ones, and (b) a unit of 15 ones. A person assimilating 15 with only (b) is coordinating two levels of units; a person assimilating only one level of unit requires *activity* to think of 15 as (b) (see Hackenberg, 2007). Steffe and Olive (2010) describe students' construction of fractions schemes as hierarchical, beginning with the *partitive unit fraction scheme* (PUFS). Partially as the result of *reorganizing* (Steffe, 2001) their ways of thinking about whole numbers to fractions, students construct the *partitive fraction scheme* (PFS), the *reversible partitive fraction scheme* (RPFS), and the *iterative fraction scheme* (IFS). For this study, we tested quantitatively whether there is a positive association between whole number units coordination and fraction scheme construction.

Methods/Results/Implications

We conducted one-on-one clinical interviews with 50 sixth-grade students in the Southeast United States. To assess fractions schemes, we used tasks modified from Wilkins, Norton, & Boyce (2013). For whole number units coordination, we used tasks modified from Hackenberg & Lee (in press). In the poster, we will present excerpts from our prompts and materials used in the assessments as well as cross tabulations of the results. Statistical analysis revealed a strong positive relationship between whole number unit coordination and fraction scheme construction (Somers' $d = .786$, exact $p < 0.001$, two-tailed). An interpretation is that one can expect to reduce the error in predicting students' fractions schemes by 78.6% if their whole number units coordination is known. Five cases did not fit the hypothesized hierarchy, and in each case, a student was assessed with a PUFS, but only one level of whole number unit. Future qualitative research is warranted to investigate this phenomenon.

WHY DO DIAGRAMS INCREASE LEARNING FROM LESSONS?

Virginia Clinton
University of Wisconsin
vclinton@wisc.edu

Martha W. Alibali
University of Wisconsin
mwalibali@wisc.edu

Mitchell J. Nathan
University of Wisconsin
mnathan@wisc.edu

Relevant visual representations, such as diagrams, can increase learning from textbooks (Mayer, 2009). There are two proposed reasons for the benefit of diagrams. One is that diagrams increase learning because they make the corresponding text easier to comprehend. This is because diagrams convey information in a manner that text cannot (Schnotz, 2002). The second is that students make connections between the visual information in the diagram and the verbal information in the text. These connections may deepen their comprehension of the material, thereby increasing learning (Mayer, 2009). Despite these claims, the influence of diagrams on both text difficulty and making connections has not been well examined.

The purpose of our study is to understand why diagrams increase learning from lessons. To address this issue, we randomly assigned undergraduates ($N = 36$) to read a probability lesson either with or without diagrams, while their eye movements were recorded. Students whose lessons included diagrams solved more probability problems correctly at post-test than did students whose lessons did not include diagrams. Students whose lessons included diagrams also had smaller average pupil size and spent less time reading the text than did students whose lessons did not include diagrams. Pupil size and reading times typically increase with task difficulty (Rayner, 1997; van Gog et al., 2009); therefore, this finding indicates that the diagrams lessened the difficulty of reading the lesson. In addition, students whose lessons included diagrams frequently looked to and from the diagram and the text. Their looks to and from the diagram and text may indicate that they were integrating the visual and verbal representations in the lesson (Mason, Tornatora, & Pluchino, 2012).

These findings indicate that both of the previously proposed reasons may explain why students whose lessons included diagrams answered more problems correctly than did students whose lessons did not have diagrams. One is that the diagrams made the lesson text easier to understand; therefore, students could focus their efforts on extracting the content of the lesson, rather than working to comprehend the text. The other is that diagrams encourage students to make connections within the lesson material, which prompts deeper comprehension. These findings enrich our understanding of the benefits of visual representations.

COLLEGE STUDENTS' APPROACHES TO SOLVING WORD PROBLEMS: A COMPARISON

Ryan D. Fox
Penn State-Abington
rdf16@psu.edu

This study builds on the work of a previous study (Fox, 2012, 2013). In the previous study, I investigated how pre-service teachers early in their preparation answered word problems involving fractions and proportions. In the new study, I want to expand the population under investigation: instead focusing solely on pre-service teachers, I want to investigate how students at the same institution outside of the education program would answer similar questions. The primary research question guiding this study is: in what ways do college students who are not aspiring teachers provide solutions to word problems that differ from college students who are aspiring teachers? This report focuses on the results of six participants in this study.

This study used the same method as the study for pre-service teachers: I interviewed each participant up to four times. All interviews were recorded using both audio and video recording devices. Across the first three interviews, I asked each participant a total of up to 25 word problems. The word problems were identical to the study with pre-service teachers. In the fourth interview, the participant and I reviewed the questions and responses the participants provided from the previous three interviews. The first three interviews in this sequence satisfied my understanding of Steffe and Thompson's (2000) definition of exploratory teaching, where I can, as a teacher-researcher, "become thoroughly acquainted, at an experimental level, with students' ways and means of operating in whatever domain of mathematical concepts and operations are of interest" (p. 274).

Participants in this study appeared to have different approaches than the early pre-service teachers solving the same word problems (Fox, 2012, 2013). For example, one of the early pre-service teachers used pictures and provided explanations to her solutions (Fox, 2012). Many of the students in the current study, however, tended to provide only a single answer to a question. When probed, what explanations the participants provided typically referenced a recollection of rules they remembered from earlier in their schooling. Many of the participants in the current study mentioned they had not revisited similar concepts in several years, suggesting their own recollection of rules tended to be either faulty or incomplete. Additionally, a variety of explanations exist across the participants in this study. Additional work associated with this study and additional analyses of already collected data could yield confirming results, or provide meaningful insights into additional responses to the same research question.

HOW STUDENTS BUILD MATHEMATICAL PRACTICES THROUGH ANALYZING OTHER STUDENTS' WORK

Sarah Gilchrist
The Ohio State University
gilchrist.42@osu.edu

Common Core State Standards for Mathematics, now adopted by 46 states across the country place a sharp focus on the need to assist learners to act as mathematicians; use mathematics to model phenomenon, search for patterns and to describe regularities. Most specifically, the standards demand that the students must learn to construct viable arguments and critique the reasoning of others (practice standard 3). This recommendation for learners' practice is compatible with those proposed for effective teaching: teachers should capitalize on analyzing students' mathematical work for orchestrating learning opportunities for children (Kazemi & Frank, 2004; Cameron et al, 2009). Research has established that attention to "unexpected results and even false solutions offered by students" can enrich student learning (Manouchehri, 2007). This body of work, small in quantity, unanimously suggests that concentrating on analysis of classroom produced work can potentially advance learners' mathematical cognition. Despite this, there is a paucity of research that highlights how learners might be assisted in developing the capacity to learn to analyze and critique the views of others with the goal of learning from the experience.

In this work we examined students' mathematical analysis of peers' mathematical work with the aim to trace the kinds of learning that may have been derived from the experience. The participants included students enrolled in two sections of an undergraduate first semester calculus course, around 20 students in each section. Participants were given three tasks over a period of three months. These tasks were designed to identify both their mathematical approaches to solving the problems and their conceptual understanding of key calculus concepts. The participants worked on each task individually first and submitted their handwritten work to the professor. They were then provided with selective sample of responses on the same tasks. These artifacts were de-identified and also came from students in the other section of the course, not their own. Students analyzed each artifact mathematically and wrote their analyses. Finally, students reworked the original task, often changing their solution.

The data consisted of the handwritten work done throughout the process. Data analysis consisted of three rounds. For the first round, student work was analyzed with respect to mathematical conceptual understanding. Misconceptions, argument structures as well as class trends were identified. The second round focused on the students' mathematical practices on each task as defined in the Common Core Standards (2012). The third round of analysis examined the students' mathematical practices over time, across the three tasks.

Results showed that when examining other students' work and then returning to their own work, students (1) increased the number of mathematical features they were considering, (2) improved their ability to judge the validity of their own mathematical reasoning, and (3) created more coherent and viable arguments. However, some students were convinced by arguments that looked mathematically sophisticated, even if they had substantive conceptual flaws.

Spatial reasoning involves thinking about the location of objects in space, their attributes, the paths they take and how they are related to each other (Newcombe, 2010). Of the different types of spatial reasoning, spatial visualization and more specifically, mental rotation, is highly correlated to mathematics performance. In their document on curricular focal points, NCTM (2008) has recommended that at least half of the early years mathematics curriculum be focused on geometry, measurement, and spatial reasoning. As a result, there is a need to develop lesson sequences that focus on spatial reasoning and measures to assess this ability in early childhood. Furthermore, recent studies have shown that spatial reasoning is malleable and can be improved (Uttal et al., 2012). This underscores the importance of laying a foundation for spatial reasoning in the early years to allow for future improvement.

To address the paucity of research on spatial reasoning in the early years and particularly in mental rotation, we have developed a measure to assess mental rotation in young children that is developmentally appropriate. Unlike typical measures of mental rotation, this measure presents children with actual 3D figures, which allows them to physically manipulate the objects. It also lends itself to direct strategies called upon during performance. Analyzing children's task performance showed that even very young children were capable of mental rotation and provided key insight into children's mental rotation strategies. These findings provided the foundation on which subsequent lessons were designed. We conclude by providing an example of a grade 1 lesson designed to develop children's spatial reasoning and 3D mental rotation abilities.

ABSTRACTING AND GENERALIZING: PROCESSES OF MATHEMATICAL THINKING

Doris Jeannotte
Université du Québec à Montréal
doris.jeannotte@uqam.ca

Keywords: Reasoning and Proof

Helping students develop their mathematical reasoning (MR) is a goal of several curricula. Based on this goal, this research project aims to qualify from a theoretical perspective two of the mathematical reasoning processes that are considered to occur in class. To do so, a literature search based on *anasynthesis* (Legendre, 2005) was undertaken. From the analysis of the mathematics education research literature on MR, several processes would appear to be linked to MR. One of these is generalization, but, as has been pointed out by Davis and Hersh (1981) and White (1993), abstraction and generalization are sometimes used as synonyms. To better understand what it means to generalize and to abstract and their relation to MR, a theoretical analysis was carried out.

A commognitive framework (Sfard, 2007) underpinned the anasynthesis of the literature. From a commognitive point of view, MR is a discursive process that derives utterances about objects or mathematical relations by exploring the relations that tie them together. By this, we mean that MR extends an existing discourse about already existing mathematical objects. In contrast, mathematical thinking is a synonym for mathematical discourse. It is composed of particular wordings, mediators, narratives, and routines. It is more than MR. MR is a kind of mathematical thinking process that contributes to its development by broadening it with derived utterances.

The analysis points out that the principal difference between generalization and abstraction is a discursive one. Generalization leads to discourse extension. There is coherence between the old and the new one. No rules are changed; only new information about objects already constructed is built. Abstraction leads to a new discourse, new rules. The old discourse then seems limited, even *passé*, from this new vantage point. At the heart of the matter, one can ask about the role played by reasoning, that is, by inferring, in the process of abstraction. Rather, it could be described as a process that is developed by cycles of individualization of interpersonal discourse and (re)communication of it.

Because generalization and abstraction are linked to mathematical reasoning in the mathematics education literature, a commognitive perspective can have an impact on mathematical reasoning studies in this field. As a matter of fact, this perspective leads to rejecting abstraction as a mathematical reasoning process. While both may be considered processes of mathematical thinking and learning, and can influence each other, one cannot be subsumed within the other.

COORDINATING REPRESENTATIONS OF COVARYING QUANTITIES: LINKING DYNAMIC GRAPHS & FILLING AREA ANIMATIONS

Heather Lynn Johnson
Univ. of Colorado Denver
heather.johnson@ucdenver.edu

Evan McClintock
Univ. of Colorado Denver
evan.mcclintock@ucdenver.edu

Jennifer Ahmed
Univ. of Colorado Denver
jennifer.ahmed@ucdenver.edu

Purpose

Researchers have incorporated dynamic environments involving multiple linked representations of covarying quantities when investigating middle and high school students' reasoning about change (e.g., Kaput & Schorr, 2008; Saldanha & Thompson, 1998). While dynamic environments linking animations with graphs might have potential to foster students' interpreting and forming relationships between covarying quantities, students working in such environments seem likely to engage in a wide range of reasoning. In this study (funded by a Faculty Development Grant from the University of Colorado Denver) we investigated how students interpreted and formed relationships between covarying quantities while working in dynamic environments.

Method

This research used design experiment methodology (Cobb et al., 2003) to investigate students' mathematical reasoning in whole class and interview settings involving tasks hypothesized to support students' reasoning about covarying quantities. Johnson led 6 days of whole class instruction with 4 sections of 7th grade students, then conducted follow up interviews with 7 pairs of students, selecting at least one pair of students from each section. During the interview, pairs worked with dynamic environments linking pictorial representations of an adjustable rectangle and a right triangle "filling with area" with a graph relating the changing quantities of area and height.

Results/Discussion

Students reasoning about area as a result of a calculation made comparisons between the shape of an animated object (rectangle or triangle) and the shape of a graph and interpreted variable increase as if it were constant. In contrast, students reasoning about area as a measurable attribute of a rectangle or triangle could envision how area might increase at different magnitudes when interpreting and/or predicting features of a graph relating area and side length. When the use of a procedure to calculate area was problematized for students, distinctions emerged between how students were making sense of area as quantity and how students were considering area as increasing at different magnitudes.

STUDENTS' USE OF INFORMAL REPRESENTATIONS IN PROOF CONSTRUCTION

Kristen Lew	Juan Pablo Mejia-Ramos	Keith Weber
Rutgers University	Rutgers University	Rutgers University
kristen.lew@gse.rutgers.edu	pablo.mejia@gse.rutgers.edu	keith.weber@gse.rutgers.edu

Keywords: Reasoning and Proof, Advanced Mathematical Thinking, Post-Secondary Education

Mathematicians reason from informal representations (IRs), such as graphs, diagrams, and specific examples of more general concepts, when constructing proofs (Thurston 1994). Alcock (2004) found mathematicians to use *algebraic* IRs in their proof construction in order to understand statements, generate arguments, and check arguments. Samkoff et al. (2012) found mathematicians used *visual* IRs for noticing properties and generating conjectures, estimating the truth of an assertion, suggesting a proof approach, instantiating or representing an idea or assertion in a diagram, and validating theorems through diagrams.

As such, mathematics educators suggest that students should base proofs on informal reasoning (Garuti et al. 1998). Case studies, however, show instances of students both successfully (Sandefur et al. 2012) and unsuccessfully (Pedemonte 2007) constructing proofs based on IRs. This study addresses the following research questions: (1) To what extent do IRs help students write proofs? (2) When IRs are unhelpful in students' proof construction, why are they unhelpful? (3) Do students use IRs for the same purposes as mathematicians? (4) Are there common unproductive patterns of behavior in students' usage of IRs in proof construction tasks?

Twelve senior undergraduate mathematics majors participated in task-based interviews completing 7 calculus proof construction tasks. These 84 proof attempts were analyzed for the use of 221 IRs and the purposes for which those representations were employed. Overall, 21 (25%) of the 84 proof attempts were successful. Of the 70 proof attempts using IRs, only 10 (14%) were successful. Of the 14 proof attempts without IRs, 11 (79%) were successful.

Next, we used the frameworks by Alcock (2004) and Samkoff et al. (2012) to analyze the purposes for which students used IRs. Despite 11 out of 12 participants creating 48 algebraic IRs, only 6 IRs (13%) were used for purposes similar to the mathematicians in Alcock's (2004) study. In contrast, at least 7 participants used between 5% and 38% of the 173 visual IRs for the purposes described in Samkoff et al.'s (2012) study.

These data suggest not only that IRs were not necessarily helpful to students in proof construction tasks, but also that a minority of students attempts to use IRs for the same purposes as mathematicians. To investigate why these proof attempts were unsuccessful, we used an open coding scheme and found that students often use inappropriate IRs, make misleading generalizations from special cases, get trapped in time sinks while studying IRs, and use IRs to verify a truth of a statement rather than gain insight on why it is true. These results suggest that simply advising undergraduates to use IRs is not likely to be helpful in their proof construction.

WHAT CONVINCES STUDENTS BEFORE THEY ARE TAUGHT TO PROVE: EIGHTH GRADERS' PREFERENCE ON MATHEMATICAL ARGUMENTS

Yating Liu
Old Dominion University
y1liu@odu.edu

It is well documented that mathematics learners hold different opinions from working mathematicians regarding what kind of mathematical arguments are convincing and explanatory to them (Harel & Sowder, 1998; Tall et al., 2012). However, in school mathematics students are often taught to follow the mechanic procedures to produce proofs without understanding the logic embedded within the arguments (Herbst & Brach, 2006). As a consequence, the type of proofs that students believe would earn them the highest mark can be different from what they would adopt for themselves (Healy & Hoyles, 2000), though little is known about the kinds of mathematical arguments that students would accept for their own use. Among all the age groups, 8^{th} graders are of particular interest since their opinions would help educators better understand students' thinking when they enter the conventional proof-based course in geometry and hence design more appropriate instructional techniques accordingly.

To identify and describe different types of mathematical arguments that children considered as convincing, we augmented Harel and Sowder's proof schemes (1998) and Tall et al.'s (2012) construct of embodiment to explore, from the learners' point of view, the link between evidence and conclusion when considering and evaluating mathematical arguments. Using a survey we collected data on students' judgment of and preference for different types of mathematical arguments. The survey contains four mathematical conjectures from different branches of school mathematics. Each conjecture is then followed by four distinct types of mathematical arguments to justify the conjecture. Students are asked to determine whether each of the presented arguments shows the conjecture is always true and then to choose the argument that they are most likely to adopt when justifying the same conjecture. The survey was designed to be completed online.

Over four hundred participants from five Ohio public schools completed the survey. Initial results indicated that the preference for an argument was highly diverse among individuals in every context. The results also highlighted that each individual's preference for an argument type was highly context based. In order to investigate factors that impact students' preference, the participants were divided into three groups based on their survey responses and a follow-up interview with representatives from each group was conducted so as to further study their thinking. Specifically, the three groups are composed of students who always, sometimes, and never consider an empirical argument as adequate to demonstrate the general validity of a conjecture. Detailed results of participants' responses to the survey as well as findings from the interviews will be shared during the poster session.

QUANTITATIVE REASONING IN ENVIRONMENTAL SCIENCE: LEARNING PROGRESSION FOR 6TH TO 12TH GRADES

Robert Mayes
Georgia Southern University
rmayes@georgiasouthern.edu

Franziska Peterson
University of Wyoming
fpeterso@uwyo.edu

Keywords: Learning Progressions, Reasoning and Proof, Modeling, Assessment and Evaluation

Purpose

If quantitative reasoning (QR) is to serve as a trigger for interdisciplinary problem-based pedagogies in STEM teaching, then more needs to be known about the progression of students' QR development in STEM. The purpose of this study is to verify a hypothesized learning progression for QR with environmental sciences as a context.

Theoretical Framework

The definition of QR used in this study, derived from the literature as well as prior research conducted by our QR team on a NSF funded project called Pathways (Culturally Relevant Ecology, Learning Progressions, and Environmental Literacy, DUE-0832173) is: Quantitative reasoning is mathematics and statistics applied in real-life, authentic situations that impact an individual's life as a constructive, concerned, and reflective citizen. QR problems are context dependent, interdisciplinary, open-ended tasks that require critical thinking and the capacity to communicate a course of action. Learning progressions are central to learning and curriculum design, a promising model that can advance effective adaptive instruction in QR.

Methodology

Creating learning progressions is an iterative research process that involves grounding the lower anchor in domains that for this study are accessible to 6th graders, then identifying intermediate levels of understanding through which they pass on their way to attainment of the upper anchor. The research subjects include 6th to 12th grade students in partner school districts in 3 different states. Participants will be students in science and mathematics courses selected from middle schools, junior high schools, and high schools within the partner school districts. Data collection will include student closed-form assessments completed in school science or mathematics classes. No new curricular implementation will be undertaken; the project team will only be assessing the student's current understanding of QR.

Results

The result of this research will be a revised learning progression for QR in the context of environmental science. This learning progression provides educators with major indicators of advancement of quantitative reasoning. In addition, the development and revision of the QR assessments themselves provide a potential formative assessment tool for teachers. We will discuss the results of the quantitative and qualitative analysis, as well as exploring the current state of the QR learning progression.

CHARACTERIZING STUDENT CONCEPTIONS OF SPAN AND LINEAR INDEPENDENCE THROUGH MATHEMATICAL ACTIVITY: THE CASE OF JOE

David Plaxco
Virginia Tech
dplaxco@vt.edu

Megan Wawro
Virginia Tech
mwawro@vt.edu

In this poster, we share results from a larger research project investigating linear algebra students' understanding of span and linear independence. Situating our work within the existing literature (e.g., Hillel, 2000; Sierpinska, 2000; Stewart & Thomas, 2010), we developed grounded frameworks for analyzing not only students' conceptions of span and linear independence, but also the types of mathematical activity in which students engage as they discuss the mathematical content (Authors, 2013). Briefly, we organize students' conceptions of span and linear independence in four categories: geometric, matrix algebraic, travel, and vector algebraic. Our categorizations of mathematical activities are defining, example generating, problem solving, proving, and relating. The present research comes from a series of interviews designed to utilize these respective frameworks. Specifically, we detail one participant's response to an interview question designed to engage him in problem solving activity while eliciting aspects of his conceptions of span and linear independence.

Our data draws from semi-structured individual interviews (Bernard, 1988) conducted with seven, first-year, honors STEM majors. Each interview lasted between 90 and 120 minutes. Each task in the interview protocol was designed to engage the participants primarily in one type of mathematical activity from our framework. Each task was also designed so that it used a specific type of representation of vectors (i.e., some questions presented specific *n*-tuples in $\mathbb{R}^3$, while others used more abstract notation such as **v** and **w**). For this poster, we focus our interest on one interview question that elicited interesting and diverse responses:

> Given that $\mathbf{v}_1 + 2\mathbf{v}_2 = \mathbf{v}_3$ (where $\mathbf{v}_1, \mathbf{v}_2, \mathbf{v}_3 \in V$, a vector space), develop more than one set of real numbers $\{a_1, a_2, a_3\}$ such that $a_1\mathbf{v}_1 + a_2\mathbf{v}_2 + a_3\mathbf{v}_3 = \mathbf{0}$.

We discuss how one participant (Joe) successfully engaged in the task by detailing how he drew from several different aspects of his conceptions of span and independence and coordinated these different conceptions through the activities of example generating and relating to solve the problem. Joe, like most of the participants in our study, used instantiations of *n*-tuples in $\mathbb{R}^3$ in order to find his solution. Unlike his peers, however, Joe additionally relied on a novel geometric representation to develop his response to the task and coordinated this representation with his earlier work, allowing him to provide a more detailed response.

ON THE EMERGENCE OF MENTAL MATHEMATICS STRATEGIES

Jérôme Proulx
Université du Québec à Montréal
proulx.jerome@uqam.ca

Helena Osana
Concordia University
osana@education.concordia.ca

Déborah Nadeau
Université du Québec à Montréal
nadeau.deborah@courrier.uqam.ca

Emmanuelle Adrien
Concordia University
e_adrien@education.concordia.ca

Most studies of mental mathematics concerned with analyzing students' strategies are based on an assumption that is known as the "toolbox metaphor," which implies that in solving a problem, students choose a strategy (a "tool") from a group of predetermined strategies they have acquired in the past (the "toolbox"). Recently, this metaphor has been significantly questioned by a number of researchers (e.g., Threlfall, 2002), who illustrated that there is more to solving mental mathematics problems than the "simple" re-using of already predetermined strategies. The focus becomes more about the adaptation and the creation of ways of solving *in function* of the problem at hand, and not about the use of strategies developed independently of problems. We present an example of a strategy taken from a larger study to support the view that strategies are emergent, thought on the spot, and intertwined with the specific problem at hand.

To solve 741–75, a preservice teacher explained one of her strategies in the following way:

(a) 741 – 75 is like 700 – 75 + 41.

(b) 700 – 75 is like having 7 dollars and subtracting 3 quarters. I am left with $6.25. And, 6.25 is six-twenty-five, so I add 41 to 625.

(c) To do so, I do 5 +1 is 6, 4 +2 is 6, and I have 600, so 666.

When the problem 741–75 was given, the first action undertaken by the student was to find a way to solve it, to "find a way in." This student opted for splitting 741 into the two parts, 700 and 41, and then to subtract the 75 from the 700. This would hardly be a strategy the student would have used if the work had been with paper-and-pencil, where often the standard algorithm would be applied, working through the task in an prescribed manner, mostly independent of the problem given. Each step can be seen as a "new" problem to work on, thereby finding new "ways in" to continue reasoning through the problem. Step (a) is a way to "enter" the problem; the outcome of this step (having to compute 700 – 75) places the student in front of another "problem to solve." Again, the student found a way to continue, and thus opted for finding a money context ($7 minus 3 quarters) to carry out the computation. The outcome of this leads the student to another "obstacle" in the way of the answer, which is to find a way to compute 625 + 41, leading to a strategy of splitting units, tens, and hundreds. That strategy is contingent on the problem given, but is also emergent, engaged with on the spot, when the problem is received.

In this sense, students' ways of entering problems can be seen in the form of "creating" their own problem solving contexts -- that is, of finding a way to (re)organize the problem as one of a "different" sort to solve. These strategies are conceived when students *meet* the task, resulting in a way of solving *in the moment* (and not of stepping back, looking in the "toolbox," and choosing an appropriate strategy). This conceptualization of mental mathematics can offer a new entry into strategy analysis, shifting the focus away from how known strategies are applied toward the creative nature of the mathematical activity in which students are engaged.

INTRODUCING MANIPULATIVES: TO PLAY OR NOT TO PLAY

Katarzyna Przednowek
Concordia University
katarzyna.przednowek@education.concordia.ca

Helena P. Osana
Concordia University
osana@education.concordia.ca

Allyson Cooperman
Concordia University
allyson.cooperman@education.concordia.ca

Emmanuelle Adrien
Concordia University
e_adrien@education.concordia.ca

Manipulatives have been repeatedly discussed in the literature and used in classrooms as a solution to bridging the gap between children's grasp of mathematical concepts and meaningful use of written numbers and other symbols (e.g., Fuson & Briars, 1990). For meaningful manipulative use, children must make the connection between the concrete objects and the concepts they represent; hence, manipulatives must be "encoded" as objects representing quantities (Brown et al., 2009). The representational relationships between symbol and concept may be apparent to teachers, but are not always successfully understood by children. In fact, if not used with meaning, manipulatives may hinder learning (McNeil et al., 2009). Because many teachers view and use manipulatives as play objects aimed to make mathematics more enjoyable (Moyer & Jones, 2004), it is unclear what impact such non-quantitative use of manipulatives has on children's ability to encode and use the tools as representations of quantities.

We investigated the impact of three different introductions to manipulatives on children's conceptions of the objects and their ability to use them as representations of quantities. Seventy-three first- and second-grade students ($N = 73$) from three schools in Canada were randomly assigned to three encoding conditions, plus a control group. In the Math condition, children were given a quantitative meaning of red and blue chips (Blue = 1 and Red = 10); the Game Piece group was given a non-quantitative meaning of the chips (i.e., game pieces); and the Free-Play group was encouraged to play with the chips to develop their own representations. After these introductions, we asked the students (a) about their perceived use of the chips, and (b) to show quantities below 50 (e.g., "Can you show me what 24 would look like with these circles?"). All students were then given addition instruction with written numbers in which the chips were used as supportive tools; the same interviews were conducted after the instruction.

We found that the Math group had the largest proportion of children who perceived the manipulatives as having a quantitative use (87%) in comparison to Control (50%), Game Piece (24%), and Free-Play (16%). After instruction, the proportions of perceived quantitative use increased for Control (75%), Game Piece (65%), and Free Play (68%) groups, but the instruction was not enough for them to catch up to the Math group (80%). The results also indicated that allowing children to initially play freely with the manipulatives was significantly associated with using them in a non-quantitative way prior to and after addition instruction (e.g., pre: $X^2(3) = 8.1$, $p < .05$; post: $X^2(3) = 9.6$, $p < .05$). Thus, free play with manipulatives appears to have a negative effect on children's ability to see and use them as quantities, even after instruction.

EXAMINING MATHEMATICAL THINKING IN ENGINEERNING AND MATHEMATICS STUDENTS

Jenna Tague
The Ohio State University
tague.6@osu.edu

Keywords: Advanced Mathematical Thinking, Cognition, Post-Secondary Education

Calls for improving the mathematical education of Science, Technology, Engineering, and Mathematics (STEM) students as well as a need for larger numbers of STEM graduates have been widespread in the past decade (Ferrini-Mundy & Güçler, 2009). Recent work examining mathematical literacy at the collegial level has shown that mathematical skills needed by different STEM disciplines are highly specialized (Tague, Czocher, & Baker, 2012). However, there is not yet consensus on how these skills might be supported in coursework students are required to complete (Wankat, 2008). While it might be tempting to suggest that attention be devoted to developing new courses accommodating the particular mathematical needs of different groups, such an approach tends to ignore the structures that constitute human cognitive architecture (Kirshner, Sweller & Clark, 2006). Curriculum and instruction design efforts are less likely to be effective in the absence of an understanding of how the mathematical cognition of different STEM audiences might process information differently. This poster examined the mathematical thinking of one engineering student and one mathematics student from a large Midwestern university as a starting place in addressing this gap. Each student was interviewed and given two open-ended questions and one typical “word” problem. Interviews were each approximately 90 minutes long and students were encouraged to explain their reasoning and thinking processes.

Interviews were analyzed using Valsiner’s (1997) zone theory, a sociocultural lens, for investigating the resources the students drew. Additionally, mathematical modeling cycle (Blum & Leiβ, 2007) allowed for cataloguing the particular phases involved in the participants’ mathematization process. Initial results indicate that the mathematics student was comfortable creating parameters and estimating values whereas the engineering student primary focus was on accuracy. The engineering student also validated not just the numerical estimates he made, but also the methods of solution that he was considering. Differences and similarities between the mathematical thinking of the two students will be discussed as well as possible instructional implications.

COMPARING THE RELATIVE LIKELIHOOD OF EVENTS: THE FALLACY OF COMPOSITION

Egan J Chernoff
University of Saskatchewan
egan.chernoff@usask.ca

Gale L. Russell
University of Saskatchewan
gale.rusell@usask.ca

The objective of this article is to contribute to the documented dearth of research on teachers' probabilistic knowledge. Prospective teachers of elementary school mathematics were asked to identify which result from five flips of a fair coin was least likely to occur. Participants, instead of being presented with sequences, were presented with events, that is, sets of outcomes, for five flips of a fair coin. A particular logical fallacy, the fallacy of composition, was used to analyze the juxtaposition of responses and response justifications. As a result, the fallacy of composition was found in the response justifications for both normatively incorrect and correct relative likelihood comparisons. Combing the results of this and prior research utilizing the fallacy of composition demonstrates that logical fallacies are a burgeoning area of research for those investigating relative likelihood comparisons and teachers' probabilistic knowledge.

Keywords: Probability; Teacher Knowledge

Given there is a limited amount of research on "teachers' probabilistic knowledge" (Jones, Langrall & Mooney, 2007, p. 933), one objective of this article is to continue an emergent thread of research investigating prospective mathematics teachers' probabilistic knowledge (Chernoff, in press, 2012a-c, 2011; Chernoff & Russell, 2012a, 2012b, 2011a, 2011b). A second objective of this article is to contribute to a well established domain of research, which accounts for normatively incorrect responses to relative likelihood comparisons (e.g., Abrahamson, 2009; Borovcnik & Bentz, 1991; Chernoff, 2009; Cox & Mouw, 1992; Hirsch & O'Donnell, 2001; Kahneman & Tversky, 1972; Konold, 1989; Konold, Pollatsek, Well, Lohmeier, & Lipson, 1993; LeCoutre, 1992; Rubel, 2007; Shaughnessy, 1977, 1981; Tversky & Kahneman, 1971, 1974). Yet a third objective of this article is to bolster the results of a particular research thread previously published in the conference proceedings of the annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education (Chernoff & Russell, 2011a) and the International Group for the Psychology of Mathematics Education (Chernoff & Russell, 2011b)

To meet the objectives stated above, prospective teachers of mathematics, as was the case in prior research, were asked to make a comparison of relative likelihood; however, unlike previous research (for exceptions see, for example, Chernoff, in press; Chernoff & Russell, 2011b), participants were asked not to compare the relative likelihood of sequences, but, rather, events (i.e., sets of outcomes) resulting from five flips of a fair coin. Also breaking from tradition, this research, instead of using the theories, models and frameworks most frequently associated with relative likelihood comparison research (e.g., Kahneman & Tversky, 1972; Konold et al., 1993), uses a particular logical fallacy for the analysis of results. The current set of responses to a task recently introduced to the research literature – the relative likelihood of events task (Chernoff & Russell, 2011b) – once again evidence use of the fallacy of composition (i.e., because parts of a whole have a certain property, it is argued that the whole has that property). Also once again, the fallacy of composition is evident in both incorrect and correct response justifications in the current research. The results from this current research, coupled with the results from the initial study (Chernoff & Russell, 2011b), further validate that certain prospective teachers of mathematics use the fallacy of composition when making relative likelihood comparisons. In line with this point, it will, further, be argued that logical fallacies are a

viable venue for future research investigating relative likelihood comparisons and teachers' probabilistic knowledge.

A Brief Summary Of Prior Research

Research into probabilistic thinking and the teaching and learning of probability has, in the past, seen a focus on normatively incorrect responses. Specific to the field of mathematics education, the theories, models and frameworks associated with heuristic and informal reasoning – rooted in the notions of conceptual analysis (Thompson, 2008; Von Glaserveld, 1995), grounded theory (Strauss & Corbin, 1998) and abduction (Lipton, 1991; Peirce, 1931) – have, traditionally, accounted for normatively incorrect responses to probabilistic tasks. Chernoff (in press, 2012a-c, 2011) and Chernoff and Russell (2012a, 2012b, 2011a, 2011b) have recently provided detailed accounts of (the history of) the theories, models and frameworks associated with heuristic and informal reasoning in the field of mathematics education and are (given the boundaries associated with the present venue) recommended to the reader.

More recently, a burgeoning area of research suggests that fallacious reasoning, more specifically, the use of logical fallacies, can account for certain normatively incorrect responses to relative likelihood comparisons. For example, Chernoff (in press) and Chernoff and Russell (2011b) utilized the fallacy of composition (when an individual infers something to be true about the whole based upon truths associated with parts of the whole) as a framework to anlayse relative likelihood comparison responses. Prospective mathematics teachers were asked to determine which of five possible coin flip sequences were least likely to occur. As was the case in similar research (e.g., Chernoff & Russell, 2011a), the fallacy of composition accounted for normatively incorrect responses to the task. More specifically, the researchers demonstrated that participants referenced the equiprobability of the coin, noted that the sequence is comprised of flips of a fair coin and, as such, fallaciously determined that the sequence of coin flips should also have a heads to tails ratio of one to one. In other words, the properties associated with the fair coin (the parts), which make up the sequence (the whole), are (fallaciously) expected in the sequence. As a result, the fallacy of composition, in addition to the traditional theories, models and frameworks associated with heuristic and informal reasoning, accounted for certain normatively incorrect responses to a probabilistic task.

Chernoff and Russell (2012a, 2011b) further established that certain prospective mathematics teachers, when asked to identify which event (i.e., outcome or subset of the sample space) from five flips of a fair coin was least likely to occur, did not use the representativeness heuristic (Kahneman & Tversky, 1972), the outcome approach (Konold, 1989) or the equiprobability bias (Lecoutre, 1992). Instead, they again demonstrated that participants utilized the fallacy of composition. Worthy of note, the fallacy of composition accounted for both normatively correct and incorrect responses to the new relative likelihood comparison task. As mentioned, this article extends previous research utilizing the fallacy of composition.

The Fallacy Of Composition

The fallacy of composition, as a theoretical framework for the analysis of response justifications for relative likelihood comparisons, has revealed a new approach to account for normatively incorrect responses. Moreover, the fallacy of composition has proven a viable approach for both relative likelihood comparisons between sequences and events. Given that the current research tasks participants with relative likelihood comparisons between events, the fallacy will be used for the impending analysis of results.

Essentially, the *fallacy of composition* occurs when an individual infers something to be true about the *whole* based upon truths associated with *parts of the whole*. For example: Bricks (i.e., the parts) are sturdy (i.e, the truth). Buildings (i.e., the whole) are made of bricks (i.e., the parts). Therefore, buildings (i.e., the whole) are sturdy (which is not necessarily true).

As will be demonstrated throughout the analysis of results, certain participants in this research inferred certain truths associated with individual coin flips to be true for events, that is, sets of outcomes. Prior to this analysis, however, certain methodological components (e.g., Task and Particpants) are discussed.

Task

As seen in Figure 1 below, the task used in this research is the same task recently introduced to the research literature (Chernoff & Russell, 2011b).

Which of the following is the least likely result of five flips of a fair coin?
a) three heads and two tails
b) four heads and one tail
c) both results are equally likely to occur
Justify your response...

Figure 1: The Relative Likelihood Of Events Task

Unlike research involving sequences of coin flips, the relative likelihood of events task possesses a normatively correct response (i.e., "four heads and one tail") and two normatively incorrect responses (i.e., "three heads and two tails" and "both results are equally likely to occur"). See, for example, Chernoff and Russell (2011b) for further details associated with history and design of both relative likelihood comparison tasks and the relative likelihood of events task.

Participants

Participants in our research were (n =) 54 prospective mathematics teachers enrolled in a methods course designed for teaching elementary school mathematics. More specifically, the 54 participants were comprised of two classes, containing 26 and 28 students, taught by the same instructor. Participants were presented with the relative likelihood of events task and were allowed to work on the task until completion. Of note, the participants had not answered any of the other versions of the relative likelihood task prior. Further, the topic of probability had yet to be discussed in class at the time of the research.

Results

Participants' responses fell into three categories. The majority, 38 of the 54 participants (or 70%), incorrectly declared that the events (three heads and two tails and four heads and one tail) were equally likely to occur. Further, fourteen of the 54 participants (or 26%) correctly declared that four heads and one tail was least likely (of the events presented in the task) to occur and two participants (or 4%) declared that three heads and two tails was least likely to occur.

Table 1: The Numerical Breakdown Of Responses

Number of participants	Three heads and two tails	Four heads and one tail	Equally likely
Class A (26)	1	8	17
Class B (28)	1	6	21
Total (54)	2	14	38
Percentage (100)	**4%**	**26%**	**70%**

Given the boundaries associated with the present venue (i.e., the 8 page limitation), the responses from eleven individuals – five from individuals that declared the events equally likely to occur and

six from individuals that declared four heads and one tails as least likely – are now featured in the analysis of results.

Analysis Of Results

The response justifications from certain individuals reveal the fallacy of composition when comparing the relative likelihood of the events they are presented. Given that use of the fallacy of composition is witnessed in the justifications for both incorrect and correct responses to the task and, as such, the analysis of results is organized accordingly.

Both Results Are Equally Likely To Occur (Incorrect Response)

Responses from (more than) 5 of the 38 individuals that declared the events were equally likely to occur evidence (to varying degrees) use of the fallacy of composition. Consider, for example, the responses from Marie Hank and Walter, who, respectively, declare that "either outcome could occur equally," "both outcomes are equally likely" and "it is just as likely for either outcome" because of (for all three of them) the equiprobability of flipping a fair coin.

Hank: Both outcomes are equally likely to occur because the probabilty of getting a head or tail is the same.

Marie: either outcome could occur equally. each time the coin is flipped there is a 50 50 chance that the coin will land with a certain face up.

Walter: It is just as likely for either outcome or any possible outcome (1H+4T, 2H+3T, 3H+2T, 4H+1T) since there is an equal chance of either occuring on each flip.

Discussed in terms of the theoretical framework, although Marie and Frank declare that the "outcome(s)" (i.e., the building) are equally likely (i.e., sturdiness of building) because of the equiprobability of the coin (i.e., sturdiness of the brick), and although Marie makes reference to the equiprobability each time the coin is flipped, their responses do not (explicitly) declare that the "outcome(s)" they are discussing are comprised of five flips of the coin (i.e., the building is made of bricks). Walter extends the argument of Hank and Marie to further declare that not only are the two outcomes they are presented are equally likely, but, further, "any" (of course, Walter is "missing" the all heads and all tails outcomes) of the outcomes are equally likely because of the equiprobability associated with the flip of a fair coin.

The responses of Skyler, Junior and Walter (differently) reference that the events are comprised of five flips of a fair coin. Consider, then, the responses from Sklyer and Junior.

Skyler: Each flip of the coin has the same odds of having heads land face up as having tails land face up. If you flip the coin once, there is a 50% chance you'll get a tail, and 50% chance you get a heads. The next time you flip the coin, the result is not dependent or related to the result of the first flip in any way, so the odds of flipping a tails the second time is still 50%, regardless of what the outcome was the first flip (same goes for head). This continues for all five flips.

Junior: on each flip of the coin there exists a 50:50 chance of heads or tails occurring. therefore, the combinations even when aggregated together have the same chance of occurring.

Like Hank and Marie, Skyler and Junior, in their responses, contend that the events are equiprobable because of the equiprobability associated with the coin flip(s). Discussed in terms of the fallacy of composition, the responses from Sklyer and Junior reference the equiprobability (i.e., sturdiness) associated with each coin flip (i.e., brick); further, their responses reference that the event (i.e., the building) is comprised of coin flips (i.e., bricks); and, as such, the outcome(s) should be equiprobable (i.e., the building made of sturdy bricks should be sturdy) or, in the words of Junior, "even when aggregated together have the same chance of occurring." Skyler and Junior (and, arguably, Hank and Marie) inferred the equiprobability of the events based upon the equiprobability associated with the flip of a fair coin. Put in more general terms, they used the fallacy of composition when determining which event was least likely to result from five flips of a fair coin.

Four Heads And One Tail (Correct Response)

As presented above, the responses from certain individuals that incorrectly declared both results equally likely to occur demonstrate use of the fallacy of composition when comparing the relative likelihood of events. As will be presented below, the responses from certain individuals that correctly determined that four heads and one tail was least likely (of the events presented) to occur also evidence use of the fallacy of composition. However, as will be evidenced in the six responses that follow, the result established through use of the fallacy of composition, that is, that the events are equally likely to occur, is subsequently used to determine that four heads and one tail is least likely to occur. Stated in more general terms, the participants are fallaciously arriving at the "correct" response.

Consider, for example, the similar yet different responses from Gale, Mike and Saul who all make reference to an expected ratio of heads to tails for the outcome.

> *Gale:* Four heads and one tail is least likely because each flip gives you a 50% chance of getting either heads or tails so it is more likely you would get closer to answer a.
>
> *Mike:* a – more likely since 3:2 is closer to 1:1 than 4:1 is. When flipping a coin the outcome should be similar to 1 head to 1 tail although it usually isn't.
>
> *Saul:* Three heads and two tails are more likely b/c there is only 2 options so there is a 50/50 chance of each happening, so it is more likely that the outcomes of heads = tail ratio will be equal or close to equal rather than further apart.

All three of the above responses are similar. For example, all three responses declare that the four heads and one tail outcome is least likely to occur because the ratio of heads to tails, that is, four to one, is farther "away" from the expected ratio of heads to tails, that is, one to one, than the "closer" ratio of heads to tails, that is, three to two. Alternatively stated, as Mike succinctly writes, "[three heads and two tails] – more likely since 3:2 is closer to 1:1 than 4:1 is." Further, also garnered from the responses above, participants (as was the case for participants in the previous section) inferred the equiprobability of the events, that is, the expected one to one ratio of the outcomes, based upon inferred equiprobability associated with the flip of a fair coin.

Discussed in terms of the fallacy of composition, the responses of Gale, Mike and Saul (again to varying degrees) reference: the equiprobability (i.e., the sturdiness) associated with the flip of a fair coin (i.e, the brick); the outcome (i.e., the building) being comprised of five flips of a fair coin (i.e., bricks); and, as such, expected, fallaciously, the outcome (i.e., the building) to have an equal ratio of heads to tails (i.e., the building to be sturdy). Subsequently, Gale, Mike and Saul utilize their fallacious conclusion, that is, both sequences should have a one to one ratio of heads to tails (as is the case for the flip of a fair coin), to analyze which of the outcomes they are presented in "closest" in terms of their expected ratio. In all three instances above, the outcomes with a four to one ratio of heads to tails is declared "further away" and, thus, is "correctly" determined as least likely to occur.

Similar (in conclusion) to the responses of Gale, Mike and Saul, Jesse, Jane and Gus also reference an expected ratio of heads to tails, but, unlike Gale, Mike and Saul, instead of referencing "closeness," reference the unlikeliness or unevenness or inequality associated with obtaining a four to one ratio of heads to tails when expecting a ratio closer to one to one.

> *Jesse:* fair coin would give 50/50 chances so 5 flips should be more equal results than 4:1
>
> *Jane:* You're least likely to flip 4 heads and 1 tail, as opposed to 3 heads and 2 tails. Each flip has a 50% chance of flipping either one. That makes is unlikely that you will flip 4/5 of the same side.
>
> *Gus:* b) because you have a 50/50 chance of getting a head or tail each time you flip. Therefore, getting an even amount of each is more likely than all on one side as in b.

Again, all three of the above responses are similar. The three responses declare that the four heads and one tail outcome is least likely to occur because (with an fallaciously expected ratio of one to one for heads and tails) having "4/5 of the same side" is unlikely or "getting an even amount of each is more likely" or there should "be more equal results than 4:1." Again, the ratio of heads to tail, that is,

one to one, is still farther "away" than three to two, but the terminology used by Jesse, Jane and Gus is different than for Gale, Mike and Saul. Further, also garnered from the responses above, participants (as was the case for participants in the previous section) inferred the equiprobability of the events, that is, the expected one to one ratio of the outcomes, based upon the equiprobability associated with the flip of a fair coin.

Discussed in terms of the fallacy of composition, the responses of Jesse, Jane and Gus (again to varying degrees) reference: the equiprobability (i.e., property of the part) associated with the flip of a fair coin (i.e, the part); the outcome (i.e., the whole) being comprised of five flips of a fair coin (i.e., parts); and, as such, expected, fallaciously, the outcome (i.e., the whole) to have an equal ratio of heads to tails (i.e., the whole to have a property associated with a part). Subsequently, Jesse, Jane and Gus, like Gale, Mike and Saul, utilize their fallacious conclusion, that is, both sequences should have a one to one ratio of heads to tails (as is for the case of the flip of a fair coin), to analyze which of the outcomes they are presented is most "equal" or "even" in terms of their expected ratio. In all three instances above, the outcomes with a four to one ratio of heads to tails is declared too uneven or not equal enough and, thus, is "correctly" determined as least likely to occur.

Concluding Remarks

The fallacy of composition is evident in the response justifications for both normatively incorrect and correct relative likelihood comparisons. For those individuals that incorrectly determined that both events were equally likely to occur, their responses referenced the equiprobability (stated differently by different individuals) of individual coin flips, that the outcomes presented were comprised of five flips of a fair coin and, thus, fallaciously concluded that the events must also be equiprobable. Alternatively, normatively correct relative likelihood comparisons were accompanied with logically fallacious response justifications. The responses from the latter participants also referenced the equiprobability of a single flip of a fair coin, that outcomes were comprised of flips of a fair and, thus, (also) fallaciously concluded that the ratio of heads to tails for the outcomes should as close to one to one as possible. Subsequently, based on this fallacious reasoning, certain participants deemed the outcomes four heads and one tails too "far away" from the expected one to one ratio, whereas other participants deemed the four heads and one tail outcome as too uneven or unequal. As demonstrated, the fallacy of composition is evidenced in both normatively incorrect and correct response justifications.

Discussion

In terms of research investigating relative likelihood comparisons, the use of logical fallacies, particularly the fallacy of composition, is a relatively recent endeavour. However, when the results of the current research are combined with previous research of Chernoff & Russell (2011b), as seen in Table 2, consistencies in the results, numerical and otherwise, are beginning to emerge.

Table 2: Current, Previous And Combined Results

Number of participants	Three heads and two tails	Four heads and one tail	Equally likely
Results of current study			
Class A (26)	1	8	17
Class B (28)	1	6	21
Total (54)	2	14	38
Percentage (100)	**4%**	**26%**	**70%**
Results of previous study			
Total (63)	5	12	46

Percentage (100)	**8%**	**19%**	**73%**
Combined results			
Total (117)	7	26	84
Percentage (100)	**6%**	**22%**	**72%**

Logical fallacies, and, in particular, the fallacy of composition, are proving an effective means when accounting for normatively incorrect, inconsistent and sometime incomprehensible comparisons of relative likelihood (Chernoff, in press, 2012a-c, 2011; Chernoff & Russell, 2012a, 2012b, 2011a, 2011b). As such, and as asserted previously (Chernoff & Russell, 2011b), logical fallacies should be considered, in addition to the traditional theories, frameworks and models, when investigating relative likelihood comparisons (of sequences or events) and teachers' probabilistic knowledge.

THE EFFECTS OF DIAGRAMS AND QUESTIONING-WHILE-READING ON LEARNING FROM A STATISTICS LESSON

Virginia Clinton

Martha W. Alibali
University of Wisconsin
mwalibali@wisc.edu

Mitchell J. Nathan
University of Wisconsin
mnathan@wisc.edu

This study examined the effectiveness of two methods of increasing student learning from posterior probability lessons: diagrams and questioning while reading. Undergraduate students (N = 245) read a lesson in one of three diagram conditions and one of three questioning-while-reading conditions (embedded questions, elaboration interrogations, and control in which they read twice). Diagrams helped students in the control group accurately solve posterior probability problems on the posttest, but only if the information presented in the diagram was also presented in the text. Contrary to expectation, students in the control condition accurately solved more posterior probability problems on the posttest than did students in the questioning conditions. Poor answer quality for the embedded questions and elaborative interrogations is a possible explanation for the unexpected results.

Keywords: Probability, Post-Secondary Education, Instructional activities and practices

Probabilistic reasoning can be difficult for undergraduate students. One type of probabilistic reasoning, calculating posterior probability, is particularly challenging (Kahneman & Tversky, 1972). Calculating posterior probability involves considering both the probability of a particular characteristic or disease in a given population (i.e., the base rate) and the probability that the identification of that characteristic or disease is accurate (i.e., the specificity). Students frequently focus on the specificity information because they consider it more salient than the base rate (Kahneman & Tversky, 1972; Sedlemeier & Gigerenzer, 2001). Therefore, it can be challenging for students to understand how to calculate posterior probability. However, it is important to teach students about probabilistic reasoning, including skills such as accurately calculating posterior probability, so that they can be better consumers and citizens in modern society (Garfield & Ben-Zvi, 2008). The present study examined the effects of two factors that may promote student learning from a lesson on calculating posterior probability: diagrams and questioning while reading.

Diagrams

One technique that may foster students' learning is including relevant visual representations. According to the *multimedia principle*, learning is improved when texts are accompanied by relevant visuals (Mayer, 2009), because students develop a verbal mental model from the text and a visual mental model from the visuals. Students are more likely to make connections among different ideas when they have the information represented in two mental models. These connections prompt deeper processing of the text and increased learning.

At present, it is unclear whether learning is improved when information presented in a diagram is also presented in text. According to the *redundancy principle*, information presented in the diagram should *not* also be presented in the text (Sweller, Ayres, & Kalyuga, 2011), because presenting information in both text and diagram increases the amount of information the student has to process, which may diminish learning (Mayer, 2009). However, the redundancy principle is based on studies using causal diagrams for scientific concepts (e.g., Chandler & Sweller, 1991). It has not been explored with numeric information in math lessons. It is possible

that having the numeric information presented in both diagram and text could facilitate connections between the verbal and visual information. Students may be better able to connect the concepts presented in the text and diagram if the information presented in the diagram is also presented in the text. Therefore, it is uncertain if including the information in the diagram as well as in the text will improve student learning about posterior probability.

Questioning while Reading

A second technique that may improve student learning is to have the students answer questions about the lesson while reading. Two types of questions are commonly used: embedded questions and elaborative interrogations. *Embedded questions* are simple questions about specific ideas stated in the lesson. Embedded questions are useful for directing students' attention to important information. Answering embedded questions has been found to increase learning from text; however, these benefits may be limited to certain student populations (e.g., less-skilled readers, Callendar & McDaniel, 2007). *Elaborative interrogations* are typically "why" questions intended to prompt the student to integrate an idea from the lesson with other ideas from the lesson or with background knowledge (e.g., McDaniel & Donnelly, 1996; Pressley, Symons, McDaniel, Snyder, & Turnure, 1988). Elaborative interrogations are intended to stimulate deeper processing of the lesson, thereby increasing learning (e.g., Ozgungor & Guthrie, 2004). Elaborative interrogation has been found to improve learning across a variety of student populations (cf. Dunlosky, Rawson, Marsh, Nathan, & Willingham, 2013). Given the previous literature on both embedded questioning and elaborative interrogation, it is likely that including these types of questions will improve student learning from a lesson on posterior probability.

The use of questioning while reading may be particularly beneficial when visual representations are included in the lesson. Students do not always attend to the visual representations in text (Schüler, Scheiter, Rummer, & Gerjets, 2012). Embedded questioning may be useful for directing students' attention towards the visual representations, particularly if the questions are about the visual representations. In addition, integrating visual and verbal information typically promotes learning (Mayer, 2009). Elaborative interrogation may be useful for guiding students to integrate the visual and verbal information. This can be accomplished by asking elaborative interrogations that encourage the students to use information in both the diagram and the text.

The present study examined the effects of diagrams and questioning on learning about posterior probability calculations. Given the previous literature on visual representations (e.g., Mayer, 2009), we predict that students will learn more if their assigned lesson includes a diagram. However, it is uncertain whether students will learn more if the information presented in the diagram is also presented in the text. In addition, we predict that students in the two questioning-while-reading conditions will learn more than students in the control condition, who will simply read the lesson twice. Finally, we predict that students who receive both diagrams and questions will learn more than students who receive only one or the other, or neither.

Methods

Participants were 248 undergraduates at a large, upper Midwestern university who earned extra credit in their introductory psychology course for participation. Three participants left the study before completing the posttest; their data were not included. Of the remaining 245 participants, there were 158 females and 86 males (one participant did not report gender) with an average reported age of 19.05 years (*SD* = 2.89 years). English was reported as the native

language of 164 students; 80 students reported a native language other than English (one student did not report native language).

Materials

The lesson was adapted from a textbook by Heuer (1999) and included materials from Sedlmeier and Gigerenzer's (2001) experiments. There were two examples of scenarios in which base rate and specificity probabilities were presented, and then the posterior probability was calculated using natural frequencies. For the diagram conditions, there was a diagram for each of the two examples. For the diagram without redundant text condition, the information in the diagram was not also presented in the text. For the diagram with redundant text condition, the information in the diagram was also presented in the text (see Table 1).

Table 1: Lesson Excerpts from Diagram without Redundant Text Condition and Diagram with Redundant Text Condition

Diagram without redundant text	Diagram with redundant text
Imagine 100 cases in which the pilot has a similar encounter. Based on the base rate, we know how many of these encounters will be with Vietnamese fighter jets, and how many with Cambodian. Based on the specific case information, we know that 80 percent Vietnamese fighter jets will be correctly identified as Vietnamese, while 20 percent will be incorrectly identified as Cambodian. Similarly, 80 percent Cambodian fighter jets will be correctly identified as Cambodian, while 20 percent will be incorrectly identified as Vietnamese. This is shown in the diagram below.  This makes a total of 71 Vietnamese and 29 Cambodian sightings, but not all of these sightings were correct. Therefore, when the pilot claims the attack was by a Cambodian fighter jet, the probability that the fighter jet was actually Cambodian is only 12/29ths or 41 percent.	Imagine 100 cases in which the pilot has a similar encounter. Based on the base rate, we know that 85 of these encounters will be with Vietnamese fighter jets, 15 with Cambodian. Based on the specific case information, we know that 80 percent or 68 of the 85 Vietnamese fighter jets will be correctly identified as Vietnamese, while 20 percent or 17 will be incorrectly identified as Cambodian. Similarly, 80 percent or 12 of the 15 Cambodian fighter jets will be correctly identified as Cambodian, while 20 percent or 3 will be incorrectly identified as Vietnamese. This is shown in the diagram below.  This makes a total of 71 Vietnamese and 29 Cambodian sightings, of which only 12 of the 29 Cambodian sightings are correct; the other 17 are incorrect sightings of Vietnamese fighter jets. Therefore, when the pilot claims the attack was by a Cambodian fighter jet, the probability that the fighter jet was actually Cambodian is only 12/29ths or 41 percent.

For the embedded questioning and elaborative interrogation conditions, there was one question after approximately every paragraph. For diagram and questioning conditions, a question was asked after each of the diagrams. For the diagram without redundant text condition, answering the question correctly required using information from the diagram. However, for the diagram with redundant text condition, the question could be answered using information from the text or the diagram (or both). Embedded questions were simple (e.g., "How many fighter jets identified as Vietnamese are actually Cambodian?") and their answers were explicitly stated in the text

and/or clearly presented in the diagram. Elaborative interrogation questions were complex "how" and "why" questions (e.g., "How are the base rate and the specific case information used to calculate the probability the fighter jet is Cambodian?"). The answers to elaborative interrogations were implicit in the text; the participant had to connect different ideas presented in the text and/or diagrams. All lessons began with the reminder that the participant would be asked to answer questions based on the information in the lesson. The lesson in the control condition also began with the reminder that participants needed to read the lesson twice. At the end of the control condition lesson, participants were reminded that if they had only read the lesson once, they needed to go back to the beginning and re-read.

Measures

Pre/posttest. Prior to reading the lesson, participants were asked to solve the following posterior probability problem: "All medical tests have error. For example, the serum test screens pregnant women for fetuses with Down syndrome. The test is a very good one, but not perfect. Roughly 100 fetuses out of 10,000 have Down syndrome. Of these 100 fetuses with Down syndrome, 90 pregnant women will have a positive test result. Of the remaining 9,900 unaffected fetuses, 99 pregnant women will still have a positive test result. What is the probability a pregnant woman who has a positive result on the test actually has a fetus with Down syndrome?" The problem was presented only as text; no visuals were included. The posttest consisted of four posterior probability problems similar to the pretest. The problems were presented as text only; no visuals were included.

Procedure

Participants were randomly assigned to conditions. Participants engaged in the experimental tasks individually in small groups of 2 to 6. All participants in a particular group were in the same condition. All tasks were paper-and-pencil (i.e., they were not administered on a computer). After providing informed consent, participants were given a posterior probability problem to solve as a pretest. Then, they were given the lesson and an answer sheet for their questions, if they were in one of the questioning conditions. The experimenter instructed them to read the lesson carefully because they would be asked to answer questions and solve problems based on its information. Participants in the control condition were instructed to read the lesson twice. Participants in the questioning condition were instructed to answer the numbered questions in the lessons when they came to them, in the appropriate places on the answer sheet. When participants finished reading the lesson, they completed a distractor task of 21 single-digit multiplication and division problems. Then, they completed the posttest. Finally, they self-reported their demographic information. Experimental tasks were completed in a single session, which were approximately 45 minutes in length.

Scoring

Pre- and posttests. Pre- and posttests were scored for accuracy. The number of accurately solved problems was the score for the pretest and posttest. The maximum posttest score was 4.

Answers to embedded questions. Answers to embedded questions were scored dichotomously as correct or incorrect. Correct answers were scored as '1' and incorrect answers as '0.'

Answers to elaborative interrogations. Because the elaborative interrogations were more complex than the embedded questions, their answers were scored using a rubric instead of dichotomously. The rubric had the following categories: ideal, adequate, inadequate, circular, wrong, and missing. Elaborative interrogations were designed to prompt integration of concepts within the lesson. Therefore, an answer was considered ideal if it correctly included three or

more concepts presented in the lesson. Adequate answers correctly included two concepts. Inadequate answers included only one concept. Circular answers repeated the information in the question (e.g., EI: “Why is the base rate important when calculating probability?” Circular Answer: “Because it is important information you need to use to calculate probability.”). Wrong answers provided incorrect or inappropriate information. Missing answers were either responses such as “I have no idea” or the complete absence of answers. An ideal answer was scored as ‘3.’ An adequate answer was scored as ‘2.’ An inadequate answer was scored as ‘1.’ A missing, incorrect, or circular answer was scored as ‘0.’ The scores for all 6 of the answers to the elaborative interrogations were summed for a measure of answer quality.

Results

We first examined the effects of the diagram and questioning conditions on the posttest scores. We separated the participants based on whether they answered the pretest correctly (N = 47) or incorrectly (N = 198). An ANOVA was conducted with diagram condition and questioning condition as fixed factors and posttest scores as the dependent variable. Bonferroni corrections were used for multiple comparisons. Figure 1 presents the data for each of the pretest accuracy groups by condition.

For participants who answered the pretest correctly, diagrams had a positive effect on posttest scores $F(2, 45) = 8.26$, p = .001. There was a benefit of diagrams both without and with redundant text compared to the text-only condition, $t(28) = 3.04$, $p = .01$,Cohen’s $d = 1.01$; $t(28) = 3.98$, $p = .001$, Cohen’s $d = 1.26$, respectively. There was no difference between the two diagram conditions. In addition, there was no effect of questioning.

For participants who answered the pretest incorrectly, there was no overall effect of diagrams on posttest performance. However, there was an interaction between diagram condition and questioning condition, $F(2, 196) = 3.04$, $p = .02$, such that diagram condition affected performance in the read-twice control condition, $t(61) = 2.56$, $p = .04$, Cohen’s $d = .63$, but not the other questioning conditions. In the read-twice control condition, participants in the diagram with redundant text condition had higher scores than did participants in the text-only condition. There were no differences between the diagram without redundant text condition and the other diagram conditions. For participants who answered the pretest incorrectly, there was also a main effect of questioning condition, $F(2, 196) = 13.56$, $p < .001$. Unexpectedly, participants in the control condition had higher posttest scores than did participants in the embedded questioning condition, $t(118) = 4.49$, $p < .001$, Cohen’s $d = .74$, and participants in the elaborative interrogation condition, $t(154) = 4.34$, $p < .001$, Cohen’s $d = .69$.

Pretest Correct **Pretest Incorrect**

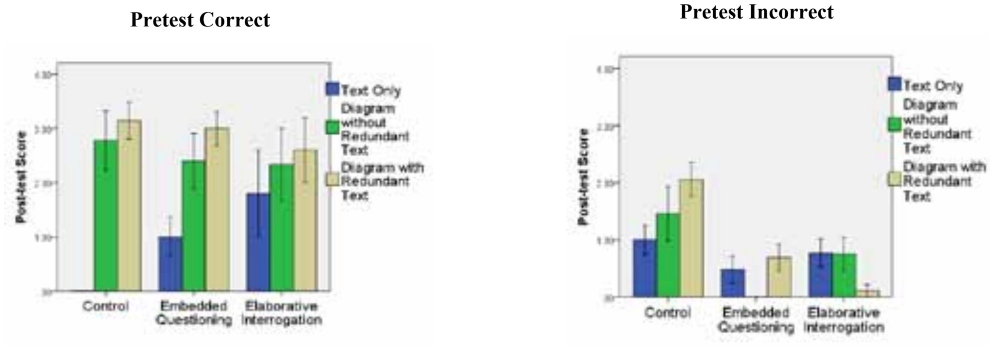

Figure 1: Post-Test Scores by Diagram and Questioning Conditions

The results indicate that diagrams were helpful for participants who initially did well on the posterior probability problem at pretest, aiding them to continue to do well on similar problems at posttest. In contrast, participants who did not understand how to answer the pretest problem benefited from diagrams when they read the lesson twice, but not when they answered questions while reading. Moreover, diagrams appear to be helpful only if they were accompanied by redundant text for participants who answered the pretest problem incorrectly. Contrary to expectations, questioning while reading was not beneficial for learning how to solve posterior probability problems. Indeed, reading twice appeared to yield higher scores on the posttest than either elaborative interrogation or embedded questioning for participants who answered the pretest problem incorrectly.

Given the unexpected finding that embedded questioning and elaborative interrogation conditions were not helpful for learning, we examined the quality of the answers to the questions in the embedded questioning and elaborative interrogation conditions (see Scoring section for scoring of answers). Because of the different patterns of findings based on pretest accuracy, we tested for differences in answer quality based on pretest accuracy. Then, we examined associations between answer quality and learning.

For the embedded questioning condition, participants answered an average of 3.08 questions correctly (SD = 1.70) out of 6 questions total. We conducted a one-way ANOVA with accuracy of answers to the embedded questions as the dependent variable and pretest accuracy as the independent variable. There were no differences in answer quality between participants who answered the pretest correctly (M = 3.00, SD = 1.70) and participants who answered the pretest incorrectly (M = 3.11, SD = 1.72). We used Pearson product-moment correlations to test for associations between accuracy of answers to the embedded questions and posttest scores. There were no associations between answer quality and posttest scores for either participants who answered the pretest correctly or participants who answered the pretest incorrectly.

For the elaborative interrogation condition, participants received an average score of 4.80 (SD = 2.27), out of a maximum possible score of 18. Approximately 37% of the answers were missing, circular, or wrong, 51% of the answers were inadequate, 9% of the answers were adequate, and 4% were ideal. We conducted the same statistical tests with the answers to the elaborative interrogations as we did with the answers to the embedded questions. As with embedded questioning, there were no differences in answer quality between the participants who answered the pretest correctly (M = 4.82, SD = 2.39) and participants who answered the pretest incorrectly (M = 4.69, SD = 1.70). Also similar to embedded questioning, there was no association between the answer quality for the elaborative interrogations and posttest scores for participants who answered the pretest correctly. However, for participants who answered the pretest incorrectly, there was a positive correlation between the quality of the answers to the elaborative interrogations and posttest scores, r = .39, p = .002.

Discussion

The purpose of this study was to examine the effects of diagrams and questioning while reading on learning from a lesson on calculating posterior probability. We had hypothesized that including diagrams in the lesson would improve learning, but were uncertain whether including text redundant with the information in the diagram would affect learning. For students who answered the pretest problem correctly, diagrams improved learning, whether or not they were accompanied with redundant text. However, for students who answered the pretest problem incorrectly, there was a benefit of diagram with redundant text, relative to text only, but only for

the control (i.e., read twice) condition. There was no reliable benefit of diagram without redundant text. These findings are consistent with the multimedia principle, which holds that including relevant visuals in lessons improves learning (Mayer, 2009).

However, our findings are inconsistent with the redundancy principle, which states that information should be presented in the text or diagram, but not both (Sweller et al., 2011). For students who solved the pretest problem incorrectly, there was no effect of redundant text. But, for students who solved the pretest incorrectly in the read-twice condition, there was a reliable benefit of diagrams only if they were accompanied by redundant text. In other words, presenting the information in a diagram *instead of* the text did not appear to be consistently helpful. For some students, the information needed to be in the diagram *as well as* the text for a benefit to be observed. It may be that presenting the information in both the text and diagram helped the students connect the two representations. The integration of the information may have led to more in-depth learning, resulting in better comprehension and application of the lesson.

We had hypothesized that answering questions while reading would have benefited learning. However, there was no effect of questioning for students who answered the pretest problem correctly. Moreover, students who answered the pretest problem incorrectly had higher posttest scores when they read twice as opposed to answer questions while reading. One possible explanation for the unexpected lack of benefit of questioning is that the quality of the answers to both the embedded questions and elaborative interrogations was generally quite poor. According to Jiang and Elen (2011), answering questions while reading only improves learning from text if students answer the questions as they were intended. On average, students answered only about half of the embedded questions correctly. This is surprising given that the answers to the questions were explicitly stated in the text; however, the undergraduate participants may have been confused by the simplicity of the questions presented to them. This confusion could have led to inaccurate answers to the embedded questions and diminished performance on the posttest for students who answered the pretest problem incorrectly. For the elaborative interrogations, students did not provide answers indicative of the deep processing these questions were intended to stimulate. The overwhelming majority of the answers to the elaborative interrogations were missing, circular, wrong, or inadequate.

Given our findings regarding answer quality, it is not surprising that both questioning conditions were detrimental, rather than beneficial, to learning for students who answered the pretest incorrectly. They were likely distracted by the questions and thereby benefited only if they read twice. However, students who answered the pretest problem correctly were not affected by questioning even though their answer quality was similar to those who answered the pretest problem incorrectly. Students who answered the pretest problem correctly may have been better able to focus on lesson content and suppress the distraction of the questions.

The results indicate that better answers to elaborative interrogations were associated with better learning from the lesson for students who lack prior understanding of the content. Therefore, benefits of elaborative interrogation might be observed if answer quality was stronger. We propose two ideas to improve answer quality in future studies. The first is practice training in which students receive examples of what types of answers are expected of them. This practice training would provide a model for the students, which could improve their answer quality (cf. Dornisch, Sperling, & Zeruth, 2011, for discussion). The second is to provide students with feedback on their answers either in the experiment, through their peers while working collaboratively (after training), or through computer-based tutoring. If these ideas could effectively improve answer quality, positive effects of elaborative interrogation might be seen.

Posterior probability, like many probabilistic reasoning concepts, is frequently challenging for students to learn. In this study, we sought to improve student learning on posterior probability problems by incorporating diagrams and questioning while reading into lessons. Our finding that diagrams assisted learning is consistent with the multimedia principle (Mayer, 2009). However, our finding that redundant text has a neutral or positive effect on learning, depending on the population, is inconsistent with the redundancy principle (Sweller et al., 2011). Our findings regarding questioning are inconsistent with our expectations based on previous literature. We believe that poor answer quality is the reason for the unexpected results, and we suggest some methods of improving answer quality. This work provides some guidance about how to improve student learning about probabilistic reasoning, while also highlighting the challenges inherent in this complex domain.

In this study, we examined the ways in which teachers' statistical knowledge is enacted during instructional practice. Using classroom video recordings from three middle-grades' teachers, we qualitatively analyzed the conversations around a task designed to develop students' knowledge of statistical sampling. Our analyses showed how teachers' selection and use of contexts during instruction impacted students' opportunities for statistical reasoning. Our research extends other literature that has begun to identify the statistical knowledge needed for teaching.

Keywords: Instructional Activities and Practices, Mathematical Knowledge for Teaching, Classroom Discourse

Purpose of the Study

Holding the view that mathematics and statistics are different fields, statistics education researchers (e.g. Groth, 2007) suggest that the knowledge needed for teaching mathematics is different from the knowledge needed for teaching statistics. As such, Groth (2007) has called for researchers to work on mapping the structure of the knowledge needed to teach statistics. To help frame our understanding of what teachers need to know to teach statistics in K-12 settings, we draw on the existing research from the Learning Mathematics for Teaching Project (Ball, Hill & Bass, 2005; Hill, Schilling & Ball, 2004). Specifically, we examine teachers' enactment of specialized knowledge for teaching (SKT), common content knowledge (CCK), knowledge of content and students (KCS), and knowledge of content and teaching (KCT). Our goal is not to provide a framework that encompasses the broad spectrum of knowledge referred to as statistical knowledge for teaching. Rather, in this paper, we focus here on one concept that lies within the "collecting data" component of statistical investigation (as outlined in the GAISE report (Franklin et al., 2007)): sampling. We describe what knowledge is needed to teach this concept and examine how this knowledge is enacted in practice in three middle grades classrooms. We focus on answering the following questions: (i) What knowledge of sampling do teachers need to possess to orchestrate productive statistical conversations? and (ii) In what ways is teachers' knowledge of sampling enacted in practice?

Theoretical Framework

Creating high-quality learning experiences requires more than simply combining practices and curricula; rather, quality teaching encompasses meaningful engagement of students in activities that foster mathematical and statistical thinking (Franke, Kazemi & Battey, 2007). The ability to support this kind of engagement requires teachers to use deep mathematical content and pedagogical knowledge (Ball, Thames & Phelps, 2008).

Mathematical Knowledge of Teaching

Much of the knowledge and skills needed to teach effectively has been encapsulated under the umbrella of mathematical knowledge for teaching (MKT). Teachers with strong MKT know the best ways to represent mathematical ideas to support students' understanding, know how algorithms are developed and why they work, anticipate students' misconceptions and plan

instruction to avoid or resolve them, and understand the typical developmental sequences of students' mathematical thinking (Ball et al., Hill, et al., 2004).

MKT encompasses four main domains of knowledge – common content knowledge (CCK), specialized content knowledge (SCK), knowledge of content and students (KCS), and knowledge of content and teaching (KCT). CCK refers to mathematics knowledge that is common to people across professions. SCK represents subject matter knowledge and skills that are unique to the work of teaching, and therefore is not commonly used in those ways by most other professions (Ball et al., 2008). KCS represents a combination of knowledge of the subject matter with knowledge about how students engage with that content. It comprises, but is not limited to, knowledge of common misconceptions, or what mathematical topics are particularly challenging for students. The fourth knowledge domain, KCT, refers to knowledge of the content combined with knowledge of ways to teach that content (Hill, et al., 2008). This involves knowing which problems are good for developing understanding of concepts, how to sequence problems, and what representations work best to support learning. Although MKT integrates these four domains, in this study we focus on highlighting the ways CCK and KCT are enacted in practice.

Knowledge Needed for Teaching About Sampling

To describe the knowledge needed for teaching sampling, we adopt Groth's (2007) approach by aligning the GAISE framework with the domains of MKT relevant to this study. The *Collecting Data* component of the GAISE framework primarily involves designing a plan to collect data and employing that plan (Franklin et al., 2007). This encompasses both mathematical and non-mathematical activities. Sampling in particular, involves primarily non-mathematical activities (Groth, 2007), such as designing data collection instruments including surveys, establishing quality control measures on data collection procedures, and determining the research design that will best answer the research questions. While much of this knowledge falls under common knowledge, research suggests that students have difficulty grasping key ideas necessary to carry out these activities successfully.

Watson and Moritz (2000) have described a hierarchy to describe the three tiers students typically move through as they develop knowledge about statistical sampling. In the first tier, students draw on their prior personal experiences of samples, such as something you get for free or a small piece, including samples of food or medicine. In a second tier, students are beginning to distinguish the difference between a sample and population and how using random or stratified sampling methods can impact results. Finally, in the third tier students understand the sample as being representative of the population, and students can recognize bias and interpret data based on the sample size and selection method used. Without quality instruction, students struggle to understand the process of sampling as described in tier 3. In a related study, Jacobs (1999) also documented the interesting ways students interpret sampling scenarios. For example, students expressed surprise if survey results contradicted what they expected; others evaluated a sampling method based on its decisiveness, citing that sampling methods that produced results in which one choice resulted in a large preponderance of the data was more valid than those in which the data might be close to a 50-50 split. Other research has shown that students are sometimes reluctant to advocate for a randomized sample. For example, when students were asked to compare three sampling methods (random, convenience, and a method where participants self-selected), 64% of students chose the self-selection method (Shaughnessy, 2007).

Knowledge Enacted in Practice

It has long been thought that a teacher's ability to instruct is strongly connected to what she knows. For several decades, mathematics education researchers have sought to empirically

substantiate the relationship among teachers' mathematical knowledge, instructional practice and student learning. From the results of various studies (see Ball, 1990; Fennema, Franke, Carpenter & Carey, 1993; Lampert, 2001), there is now strong empirical evidence to show that "…there is a powerful relationship between what a teacher knows, how she knows it, and what she can do in the context of instruction" (Hill et. al., 2008, p. 496).

Teachers' MKT is perhaps most visible in practice when they orchestrate instruction in ways that students are engaged in the intended mathematics and the richness of the mathematics is sustained throughout (Sleep, 2012) - what Sleep describes as steering instruction toward the mathematical point. To specifically examine how teachers utilize their knowledge in the act of teaching, researchers have identified characteristics of teaching through which they are able to determine the quality of instruction. Hill et al. (2008) identified six themes classified as *Elements of the Mathematical Quality of Instruction (MQI)*. These include (a) mathematical errors, (b) responding to students inappropriately, (c) connecting classroom practice to mathematics, (d) richness of the mathematics, (e) responding to students appropriately and (f) mathematical language (see Hill et al. (2008) for a full description). Although not an exhaustive list, we found that these elements aligned well with our own observations of the ways teachers' knowledge are enacted in instruction. In the next sections, we highlight how teachers implemented a task that focused on interpreting the limitations of data with bias caused by a non-representative sample.

Methods

The task (Fig 1., adapted from Rossman and Chance, 2008) is designed to have students examine how the sampling method used can impact the data collected. The intent of this task is to develop an understanding that the inferences made from data depend on how that data was collected. Students should understand that to make valid inferences, they should look at data with critical skepticism, which is an important statistical disposition (Wild & Pfannkuch, 1999).

1. On the 12th anniversary of the death of Elvis Presley, a Dallas record company sponsored a national call-in survey. Listeners of over 1,000 radio stations were asked to call a 900 number (at a charge of $2.50) to give their opinion about whether or not Elvis was really dead. It turned out that 56% of the callers felt that Elvis was alive.
   1. Identify the population of interest and the sample actually used to study that population in this example.

      Population:

      Sample:

2. Do you think that 56% is an accurate reflection of beliefs of all Americans on this issue? If not, identify some of the flaws in the sampling method and suggest how it could have been improved.

Figure 1. The Elvis Task

Participants

The participants included three middle grades teachers and approximately 110 students from one elementary and one middle school in a predominantly white, suburban school district in the Midwest. Mr. Jackson was a sixth grade teacher while Mr. Horn and Ms. Ottey taught middle school mathematics to seventh- and eighth-grade students.

Data Sources

We used transcripts of video recordings of classroom instruction and field notes to investigate how teachers' knowledge of sampling was enacted in practice. Three cameras were used; one recorded actions of the teacher, and the second and third focused on individual groups of students for the entirety of a lesson. The videotaping was supplemented with observational

field notes taken by a member of the research team.

Analysis

Members of the research team watched the classroom videos and read the transcripts of lessons where the relevant task was discussed. The transcripts were open coded and examined for statements that captured the teachers' instructional practices. Given our research questions, we developed two categories of codes – discourse codes and statistical knowledge codes. Discourse codes (e.g., revoicing, questioning, telling) aligned most closely with elements (b), (c) and (e) of the MQI, while the statistical knowledge codes (e.g., Knowledge of Sampling) aligned with elements (a), (d) and (f).

Each type of code was counted for each teacher, then the percentage occurrence of each code per category was found to determine dominant discourse types. We also used statistical knowledge codes to do a second round of data analysis. We identified all the segments of the transcripts that had a statistical knowledge code and examined the discourse around each code to describe the ways this knowledge was drawn on during the act of teaching. From the analyses we found different ways in which the teachers' knowledge of sampling were enacted in practice.

Findings

In this section, we contrast how Mr. Horn, Ms. Ottey, and Mr. Jackson introduced the Elvis task. All three teachers made explicit attempts to connect the task to students' prior experiences, but not all teachers were able to engage students in discourse that would allow them to think statistically. Prior to introducing the Elvis task, Mr. Horn asked students to identify the favorite type of music among people in their town. Several students shared, then Mr. Horn followed by asking, "how can we figure this out?" Students suggested advertising in the local newspaper or collecting data online. Calling in to radio stations was also suggested. Students then made a list of different radio stations in their local area. After documenting these stations on the board, he asked students to consider the music genre of each station. The following conversation ensued:

Mr. Horn: You guys had some great ideas about getting a survey out and kind of asking the people of Oakville to respond in a survey. If we did it through the radio, let's say we picked one of these stations.

Student: 100.3

Mr. Horn: 100.3; if we had on the radio, if we had 100.3, that station perform this survey for us and asked the people of Oakville, okay call in and tell us what is your guys' favorite radio station. We had that station list that for us, what do you think would be the most people? The most response to 100.3? What would be the favorite of Oakville? Jeremiah?

Jeremiah: It would, the station that advertised it

Mr. Horn: The station that advertised it so 100.3 plays mostly country right, why would they get more country people?

Students: That's the station.

Mr. Horn: Awww, good say that a little.

Student: That's the station.

Mr. Horn: That's the station that plays country music so people who naturally like country music are going to listen to 100.3. If we only had that radio station put out our survey?

Student: You would only get country people.

Mr. Horn: We'd only get the country people responding right?

Drew: You pick one from each…

Mr. Horn: Awwww, Drew had an excellent idea. In order to make sure that we kind of get everybody within Oakville, why don't we kind of pick one from each little group, if we had a classic rock station, we had a country station…an oldies station.

This excerpt documents Mr. Horn helping his students understand the importance of samples being representative of a population. In particular, he wanted students to understand that when data is collected from a homogeneous group of people, the results may not be generalizable to the entire population. By choosing the context of the radio station, Mr. Horn posed questions to students situated in a context to connect their personal experiences of listening to music on the radio to a larger statistical concept. In addition, Mr. Horn prepared his students to engage in the Elvis task, a problem that also involved responses of radio listeners, which was not representative of the population for other reasons. Thus, Mr. Horn's instructional choices both built on students' lived experiences and prepared students for engagement in a future task.

Ms. Ottey also found ways to connect statistical ideas to her seventh-grade students' prior experiences. During one class session, Ms. Ottey introduced the Elvis problem, and immediately engaged students in a discussion to ensure they understood the two new statistical terms – population and sample. Originally, she asked students, "What is the population of this room?" The students responded by saying twenty-eight until a student mentioned that it should really be thirty, because they had failed to include Ms. Ottey and the researcher in the room. She then asked about whether there were different sub-groups in the room (e.g., girls, adults, brown-haired people, thirteen-year olds), and noted that all of these make up the population. The excerpt below documents the discussion that followed.

Ms. Ottey: …Are you clear on population? [pause] What is a sample? If I wanted to take a sample of this group, who would I sample?

Jamie: Me! All of us!

Ms. Ottey: That would be the whole population. That would be like saying I'm going to give my breakfast survey to every person in the whole school.

Dacia: Three tables.

Ms. Ottey: Oh wait, wait!…What were you going to say?

Dacia: Well, I was just, what was your question?

Ms. Ottey: My question is: What would my sample be? If I were going to take a sample of this room, what would a sample be? [pause] Yes? [pointing to Blake] Oh, yes?

Blake: A person?

Ms. Ottey: I could take one person. That might be a sample. Maybe there's a big survey and I'm, maybe it's like student council. Let's see, who's your student council members? Okay, Jackson, Erica, Kevin, Ariel. So, those four are a sample of our class. And we use those to represent our class, right? Okay, so that would be a sample. Does it include girls? Yeah, but it includes boys, but there's a specific number. There's four. Umm, so we wouldn't have an eighth grader and have them represent our team or our class, right? Cause there are no eighth graders here. So, a sample is a small part of the population.

As Ms. Ottey helped her students to distinguish population and sample, she drew on her knowledge of her students and statistics to make several important teaching moves. For example, she recognized that these terms might be difficult for her students to distinguish, so she asked directed questions to ensure the students had a collective understanding of the terms.

By situating the discussion in terms of the student council members, the students could see how a sample is contained within a larger population. Furthermore, the members of the student council represent the members of the class, much like the data from a statistical sample are used

to represent a population. She extended this conversation by helping students to recognize the importance of considering the membership of the sample by emphasizing the need to include particular subgroups (girls) and exclude those that would not be representative of the class (eighth graders). Although the metaphor of the student council was helpful for understanding the purpose of a sample, it did have limitations. Typically, the students in a class elect their representatives on the student council. However, in statistical studies the population does not typically decide which of their members will constitute a sample. One might argue that Ms. Ottey should have disclosed this difference to her students.

As the examples of Mr. Horn and Ms. Ottey have demonstrated, using contexts that students understand can be a useful tool in helping students to think statistically and learn statistical concepts. Contextualizing a problem can also be used as a motivational tool. Mr. Jackson attempted to help his sixth-grade students recall who Elvis Presley was by playing his music.

Mr. Jackson:, …raise your hand if you know who Elvis is? This guy here. Right? [plays Elvis Presley's *Hound Dog*] … Right? [Some students begin moving arms as if they are dancing in their seats.] And Chad and Karl like to dance to it. And Bradley too. Okay? So, if we read this problem, if we read this problem: the twelfth anniversary of Elvis Presley, Bradley. On the twelfth anniversary, a Dallas record company…

Mr. Jackson introduced the Elvis problem in a way that would help students recognize Elvis Presley. For some students, the music might provide motivation to further understand the problem. However, playing music did not provide a means to engage students in statistical discourse. As evident in the excerpt, while the music played, students were dancing to the music. After giving the students several minutes to talk about the Elvis task in small groups, Mr. Jackson debriefed the discussions as a whole class.

Mr. Jackson: Do you think that 56% is an accurate reflection of beliefs of all Americans on this issue?

Gabe: Yes!

Mr. Jackson: And if not, you need to tell us some of the flaws in this method and suggest how could they improve it, how could the radio station actually improve it, okay? But before we answer that question, let's go and answer the first one. What is the population of interest? What's the population of interest? Bradley?

Bradley: People around the state.

Mr. Jackson: So you think people just around the state? Okay, what do you think?

Lanie: Everyone around the United States of America.

Mr. Jackson: Okay, Lanie thinks the population of interest is everyone around the United States of America.

Lanie: Unless it's a local radio stat—

Mr. Jackson: Unless it's just a local radio station, right, Nick?

Nick: Yes.

Mr. Jackson: But what was the sample that they actually took? Jordan?

Jordan: People who listen to the radio station.

The students' misunderstandings about sample and population are prevalent in this discussion. First, Gabe's comment suggesting that such a high percentage of Americans would believe Elvis was still alive suggests he doesn't have a clear understanding of the context. Bradley incorrectly identified the population as "people around the state." Finally, Jordan misunderstood what the sample was, identifying all people who listened to the radio station, rather than those listeners who paid $2.50 and called in.

Mr. Jackson's students had been given ample time to discuss and critique the task in small groups, so why did these misunderstandings persist? One possible explanation is that Mr. Jackson, unlike Mr. Horn and Ms. Ottey, had not framed the context and launched the task in a way that really allowed students to make sense of the important statistical ideas in the task and connect it to their personal experience in a meaningful way,. Furthermore, Mr. Jackson's primary discourse move in this excerpt was to repeat students' responses. He did not react to either correct or incorrect thinking in constructive ways.

Discussion and Conclusions

From our data, we observed that Ms. Ottey and Mr. Horn had clear understandings of population (set of entities to which inferences will be made) and sample (representative subset of the population), evident in their discussion with the students. However, to help students grasp the idea of "representativeness," having CCK of population and sample was insufficient. To build this understanding, the teachers framed the classroom discussions within meaningful contexts that connected to the students' experiences, demonstrating aspects of their KCT. In particular, by referring to the composition of the Student Council and foregrounding the need to collect data from fans of different music genres, the teachers made it clear that an appropriate sample should include all the types of people from the population. These contexts were conceptually-rich, allowing students to distinguish between population and sample and identify methods to reduce sampling bias. Mr. Jackson's choice of context was quite different; he chose to play and discuss an Elvis song prior to the discussion. While this prelude may have captured the students' attention, in contrast to the other classrooms the context did not help build meaning of the statistical concepts involved in the task. In fact, based on his interaction with the students, one could question whether Mr. Jackson's had CCK related to these concepts. Engaging students' statistical thinking requires that teachers understand the concepts (Hill et al., 2008), select appropriate contexts (Boaler, 1993; Sullivan, Zevenberger & Mousley, 2003), and know how to frame statistical questions in ways that allow students to build connections between their prior experiences and a task's embedded statistical concepts.

Teaching quality is related to how well teachers can draw on and integrate these domains of knowledge in the act of teaching to engage students in the intended mathematical (or statistical) work (Sleep, 2012). In this regard, maintaining the richness of the statistics (content), resolving misconceptions and responding (in)appropriately to students' statements were elements of practice that were enacted differently across classrooms. Although Mr. Jackson did continuously question the students, he did not deeply probe students' responses or use follow-up questions in ways that encouraged students to think critically about the ideas being discussed (Franke, et al., 2009). His interactions with students were primarily repeating students' statements, rather than fostering a discussion that could lead to the intended statistical idea. His missed opportunities to counteract students' incorrect statements served to perpetuate misconceptions held by the students. Conversely, Mr. Horn and Ms. Ottey were better able to guide the discussion towards the statistical point. They wanted students to develop a healthy skepticism of data and to acknowledge potential bias caused by non-representative samples. To do so, they drew on the experiences of the students, identified their current understanding of population, and used this information to craft questions and responses that guide the conversation towards to the intended statistical point.

As the field moves towards building a knowledge base for teaching statistics, important questions to frame this discussion include: what contexts best support students' understanding of

sampling, and statistical concepts more broadly? What are the affordances and constraints of different contexts? What contexts are effective for particular groups of students (different grade levels, rural vs. urban etc.)? What instructional practices are most effective to foreground the intended statistical ideas? The results of this paper add to this emerging body of knowledge by providing usable knowledge about ways to build meaningful contexts for statistical thinking around students' experiences. Also, we provide insight into what teacher moves work and how to deploy these moves to foreground the intended statistical ideas.

Our study, situated within graduate-level courses for teachers focused on statistics, illustrates work across institutions for making sense of teachers' statistical thinking. Using a common assessment instrument, we identify and discuss four items that indicate strong statistical thinking and two that highlight concepts with which teachers struggle. We discuss potential course elements that may be contributing to areas of success. Implications for collaborative course (re)design and shared assessment items are discussed.

Keywords: Data Analysis and Statistics, Teacher Education-Inservice/Professional Development

Introduction

Over the past 30 years, a considerable body of research has addressed students' statistical thinking from primary through tertiary schooling (cf., Shaughnessy, 2007). Over the same time frame, the role of statistics and probability has received attention in the secondary curriculum in the United States (National Council for Teachers of Mathematics, 2000; Common Core State Standards Initiative, 2010). However, as Shaughnessy and others have noted, any effort to improve the teaching and learning of statistics in secondary schools depends on the statistical knowledge of secondary teachers. To this end, many graduate programs in mathematics education and professional development efforts have begun to include more opportunities for teachers to develop their own statistical reasoning abilities, and to learn about pedagogical issues in teaching statistics. But the research base on secondary teachers' statistical reasoning is sparse (c.f., Batanero, Burrill, & Reading, 2011), and thus limits the capacity for teacher educators to design effective courses and other professional development experiences for teachers. In this paper, we report on our emerging work on collaborative design of a course for secondary teachers that focuses on teaching and learning statistical reasoning.

Working at two different institutions, the authors identified several important commonalities in the statistics education courses that we had developed independently. These commonalities included shared foci on key elements of statistical reasoning, such as the central role of variation, distribution, and the sampling distribution in developing students' inferential reasoning. Our common goals for our courses also included a focus on the central role that statistical software designed for the learning of statistics (such as *Fathom* (Finzer, 2001) and *TinkerPlots* (Konold, 2005) should play in supporting teachers in their own learning of statistics and in developing their approaches to teaching statistics. We shared a common commitment to taking the time needed to develop teachers' understandings and, hence, in both courses "coverage" of topics was on occasion sacrificed for depth of understanding. Finally, as teacher educators working in statistics, we had a common goal of gathering and analyzing data that would provide evidence about teachers' statistical reasoning and provide an empirical basis for a collaborative course design on the teaching and learning of statistics. Thus, we are not conducting a comparative course study, but rather we seek to investigate how evidence on teachers' statistical reasoning from both courses can be the basis for an on-going collaborative design of an effective statistics course for secondary teachers. In this paper, we focus on the following question: *How can assessment items on statistical reasoning provide a basis for the (re)design of learning experiences for teaching statistics at the secondary level?*

Theoretical Grounding

Recently, researchers have discussed and investigated teachers' statistical knowledge for teaching, using various frameworks and perspectives in their work (e.g., Groth, 2007, Burgess, 2011; Lee & Hollebrands 2011; Noll, 2011). Each of the emerging frameworks has identified teachers' own statistical literacy and thinking as a foundational or cornerstone aspect of their ability to teach statistics. Not many would argue this point. Though our courses aim to more fully develop secondary teachers' understanding for teaching statistics, the focus in this paper is on several key concepts in statistics and teachers' reasoning abilities with these concepts, without regard to their understanding of how to teach these concepts. If statistical literacy and thinking are essential for teachers, then teachers should have a strong foundation that is above that of students who have taken a collegiate level introductory statistics course, most of which are at the level of an AP statistics course taught in high schools. Thus, we turned to literature on assessing statistical literacy, thinking and reasoning (e.g., Garfield & Chance, 2000) for assistance in how to best assess the literacy and thinking of our teachers. Several researchers have engaged in developing, validating, and administering test items that aim to assess conceptual understanding and statistical literacy and thinking, rather than skills. One coordinated effort (delMas, Garfield, Ooms, & Chance, 2007) resulted in the Comprehensive Assessment of Outcomes in a First Statistics course (CAOS, https://apps3.cehd.umn.edu/artist/caos.html) and the collection of items at the ARTIST website (Assessment Resource Tools for Improving Statistical Thinking).

Methods

Course Contexts and Participants

Course1. Authors 2 and 3 designed and taught a one-semester graduate-level course in mathematics education to engage teachers with a range of tasks involving the investigation and exploration of statistical concepts using the software package *Fathom* (Finzer, 2001). The statistical content of the course consisted of investigations into variation and distribution, sampling distributions, confidence intervals, and inferential statistics. In addition, the course included various readings and discussions about (a) the nature of statistical reasoning and how it compares to other forms of mathematical reasoning and about (b) secondary students' learning and statistical reasoning. *Fathom* was used to support teachers' learning by providing an interface that would allow them to flexibly explore multiple graphical representations (e.g. shifting between box plots, dot plots and histograms) while being able to easily compare data sets, and to make changes to the data so as to explore conjectures. *Fathom* also provided the simulation tools necessary to create sampling distributions and representations of a population, a sample, and the sampling distribution. We saw this as critical to developing the teachers' knowledge of sampling, in order to build an understanding of formal inference.

There were 13 teachers who participated from Course1. Four participants were pre-service teachers (in a graduate licensure program), five were in-service teachers, two were in a masters program full-time, and two were doctoral students in mathematics education. Eight of the participants were female and five were male. All participants had completed the equivalent of an undergraduate major in mathematics, with all but one having had at least one course in statistics.

Course2. At a different university, another graduate-level, semester-long course in mathematics education was designed and taught by Authors 1 and 4. The course was intended for secondary and tertiary teachers of introductory statistics courses. The course had similar content focus as Course1, except that the instructors deemed it was necessary to go deeper in several explorations with data early on, and thus confidence intervals and formal inference were not discussed. Teachers in Course2 also engaged in similar readings and discussions as those in Course1. *TinkerPlots* was the main tool used in the course, though teachers also had some experiences with *Fathom*. The choice of

TinkerPlots was purposeful to engage teachers in more exploratory data analysis and to emphasize reasoning about distributions and statistical measures in multiple visual ways.

The 16 teachers in Course2 consisted of two preservice teachers enrolled in an M.A.T. program; eight teachers in a masters program with six currently teaching (3 of whom taught AP Statistics) and two in graduate school full-time; six PhD students in Mathematics Education, all of whom had recent secondary teaching experience; and one Statistics PhD student currently teaching a college-level introductory statistics course. Twelve teachers were female and four were male, with three international students within their first year of graduate work in the US. All teachers had completed an equivalent of an undergraduate degree in mathematics or statistics, and all had taken at least a first level graduate course in statistics for social science majors (content about equivalent to Advanced Placement Statistics).

Instrument

In the final week of both courses, all participants completed a 20 item multiple choice test with items in six categories: graphical representations, sampling variation, inference, data collection and design, bivariate data and probability. This selection of categories represents key concepts in introductory statistical literacy and thinking, and potentially provides us with a range of topics for which we can use as a basis for the continuing (re)design of our courses. Most items were drawn from validated instruments such as the CAOS test, with a few selected from the larger ARTIST database (https://apps3.cehd.umn.edu/artist), and one item drawn from the work of Zieffler, et al. (2007) because of its focus on informal inference (emphasized in both courses). All items have been used previously with college students, and we have known results for 19 of the 20 items that would allow for a comparison to the results from our teachers.

Analysis

We were interested in identifying the common successes and struggles with statistical reasoning displayed by our teachers, across both courses and institutions, as evidenced in their responses to this 20-item assessment. The common successes and struggles would provide us with some evidence about the areas where teachers had strong understandings of the measured concept and areas where their struggles (known from the research on college students) persisted through to the end of both courses. This evidence in turn becomes the basis for the (re)design of the courses in ways that will build on the strengths of teachers' statistical reasoning and will address areas of persistent difficulty. Thus, we first focused our attention on the items on which at least 75% of the teachers chose the correct response in both classes. We then attended to items that both sets of instructors felt assessed concepts they had spent considerable time developing in their courses, yet the response rates did not show evidence of strong statistical reasoning for either group of teachers. Due to space limitations, we discuss four questions from the strong statistical thinking category, and two items from the struggling statistical thinking category.

Results

The overall performance of our teachers on six selected items from the post-test is shown in Table 1. For comparison purposes, the last column indicates performance results of students from introductory statistics courses from the work of others. In all six items, our teachers demonstrated much higher abilities in statistical thinking.

Table 1. Comparative Results for Percent Correct on Selected Items on Post-test.

Item	Measured Learning Outcome	Course1 N=13	Course2 N=16	Comparison to Others' Results (N varies)

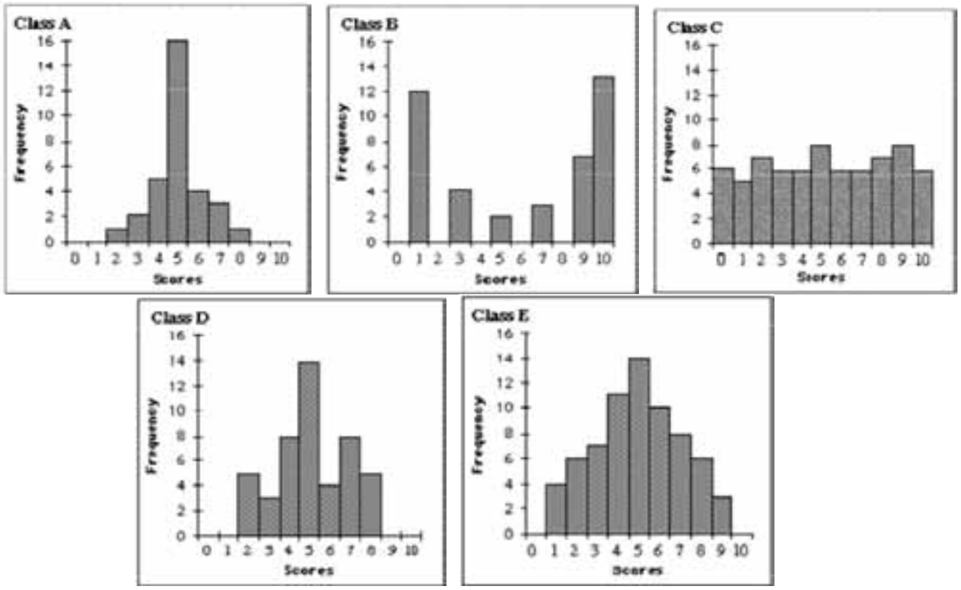
Category: Strong Statistical Thinking				
4	Ability to correctly estimate standard deviations for different histograms. Understands highest standard deviation would be for graph with the most spread (typically) away from the center.	92%	75%	46.9%[a]
7	Ability to use a frequentist approach to estimate probability of events for tossing an irregular shaped object, rather than apply an equiprobable approach	100%	75%	59%[b]
14I	Understanding of the law of large numbers for a large sample by selecting an appropriate sample from a population given the sample size.	100%	100%	65.2%[a]
14II	Ability to select an appropriate sampling distribution for a population and sample size.	77%	75%	44%[a]
Category: Struggling Statistical Thinking				
3	Understanding that a distribution with a median larger than the mean is most likely skewed left.	46%	63%	39.7%[a]
5	Understanding that statistics from small samples vary more than statistics from large samples.	54%	63%	31.9%[a]
[a]Results from CAOS administration reported by delMas et al. (2007) with participants (N) varying per item from 724-749. [b]Results reported from ARTIST database (delMas, personal communication, January 31, 2013).				

Evidence of Strong Statistical Thinking Across Groups

Most teachers in both groups (92% and 75%) were able to identify Class B (Figure 1) as the distribution that would likely have the largest standard deviation, because more of its scores are far from the mean. The concept of standard deviation was discussed explicitly in each course and teachers had an opportunity to examine research items similar to this in their reading and discussion of the work of delMas and Liu (2005). It is promising that these teachers tend to reason much better than students who have completed an introductory statistics class, of which less than 50% correctly responded to this item. Thus, explicit attention to reasoning about standard deviation of a distribution and reading about students' reasoning with this concept may help support teachers' reasoning.

Our teachers have no problem identifying a distribution for a single large sample chosen from a given population (100% correct in both courses), but did slightly less well on their ability to choose a correct graph representing a distribution of 500 sample means (Figure 2). On both parts of the item, our teachers did much better than the typical student as reported from delMas et al. (2007). This is especially encouraging since teaching the difference between a sample and a distribution of sample statistics is a particularly important, and hard to teach, concept in introductory level statistics at the collegiate and high school level (Saldanha & Thompson, 2002). Both courses spent considerable time engaging with these concepts using technological tools and reading literature about typical students' difficulties with distinguishing between a sample and a distribution of sample statistics.

Five histograms are presented below. Each histogram displays test scores on a scale of 0 to 10 for one of five different statistics classes.



Which class would you expect to have the highest standard deviation, and why?

A. Class A, because it has the largest difference between the heights of the bars.

B. Class B, because more of its scores are far from the mean.

C. Class C, because it has the largest number of different scores.

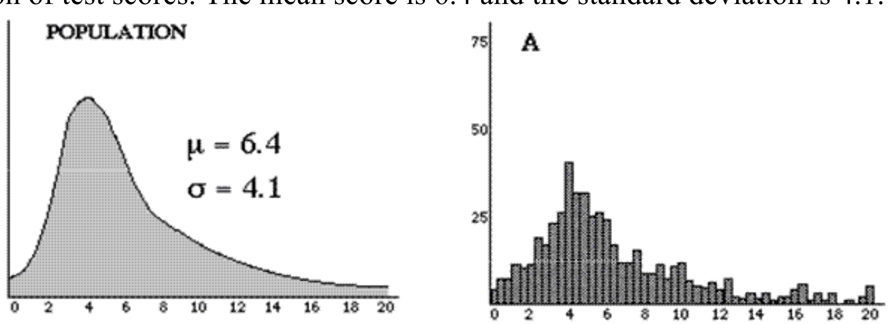
D. Class D, because the distribution is very bumpy and irregular.

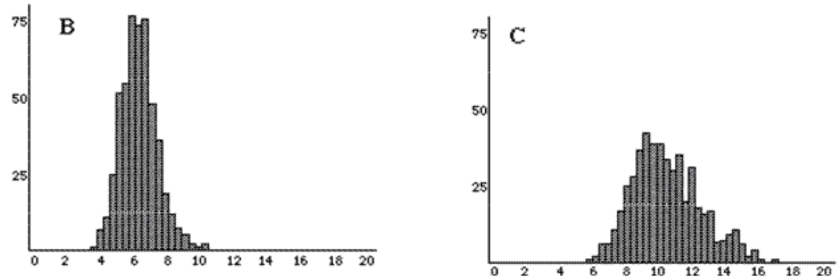
E. Class E, because it has a large range and looks normal.

Figure 1. Item 4 – Choosing Distribution with Highest Standard Deviation

Teachers in both groups also demonstrated a strong understanding of how to estimate probability of events for tossing an irregular shaped object using a frequentist approach (Figure 3). None of the teachers chose the assignment of probabilities based on a classical equiprobable approach (choice A). Three students from Course2 chose none of the above for their response; thus their reasoning for how to approach this task is unclear. If we want teachers to teach their students that an equiprobable distribution is not always the best estimate for the probability of events, then the high success rate on this item is particularly promising. Only 59% of students completing the same item in the ARTIST database chose the correct response, and 22% thought a classical approach (choice A) was the best (delMas, personal communication).

Four graphs are presented below. The graph at the top [left] is a distribution for a population of test scores. The mean score is 6.4 and the standard deviation is 4.1.





I. Which graph (A, B, or C) do you think represents a single random sample of 500 values from this population?
A. Graph A B. Graph B C. Graph C

II. Which graph (A, B, or C) do you think represents a distribution of 500 sample means from random samples each of size 9?
A. Graph A **B. Graph B** C. Graph C

Figure 2. Item 14 -- Understanding Sample Distribution and Distribution of Sample Means

A game company created a little plastic dog that can be tossed in the air. It can land either with all four feet on the ground, lying on its back, lying on its right side, or lying on its left side. However, the company does not know the probability of each of these outcomes. They want to estimate the probabilities. Which of the following methods is most appropriate?

A. Since there are four possible outcomes, assign a probability of 1/4 to each outcome.
B. Toss the plastic dog many times and see what percent of the time each outcome occurs.
C. Simulate the data using a model that has four equally likely outcomes.
D. None of the above.

Figure 3. Item 7 – Probability Measurement from a Frequentist Approach.

Teachers' Consistent Struggles Across Both Groups

In both courses, significant attention was given to understanding the relationship between a distribution and its measures of center. The teachers in both courses engaged in exploratory data analysis with *Fathom* (Course1) or *TinkerPlots* (Course2) and experienced how dynamically moving a data value in a graph impacted the mean and deviations from a mean. In addition to the focus on standard deviation discussed earlier, both courses also included readings and discussions in which common conceptions of the mean were discussed (e.g., Shaughnessy, 2006; Zawojewski & Shaughnessy, 2000). Despite this focus, many teachers did not correctly choose the appropriate distribution (Histogram b) for the given statistical measures (see Figure 4).

A study examined the length of a certain species of fish from one lake. The plan was to take a random sample of 100 fish and examine the results. Numerical summaries on lengths of the fish measured in this study are given.

Mean	26.8 mm
Median	29.4 mm

Standard Deviation 5.0 mm
Minimum 12.0 mm
Maximum 33.4 mm

Which of the following histograms is most likely to be the one for these data?

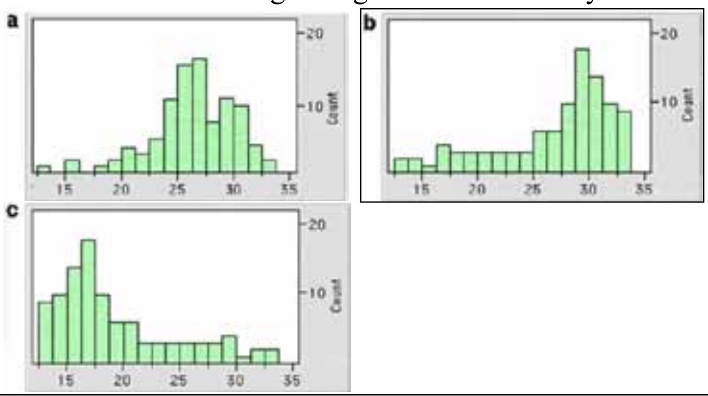


Figure 4. Item 3 – Choosing Distribution Given Statistical Measures

Given our attention to the role of sample size in variation from expected proportions, we were surprised that many of our teachers did not respond correctly to item 5 (Figure 5). While our teachers did better as a group than introductory statistics students, the most common incorrect answer (E) chosen by introductory statistics students, was also the incorrect response chosen most often by our teachers. This choice demonstrates applying equiprobable reasoning to the situation rather than considering effect of sample size.

A certain manufacturer claims that they produce 50% brown candies. Sam plans to buy a large family size bag of these candies and Kerry plans to buy a small fun size bag. Which bag is more likely to have more than 70% brown candies?

A. Sam, because there are more candies, so his bag can have more brown candies.
B. Sam, because there is more variability in the proportion of browns among large samples.
C. Kerry, because there is more variability in the proportion of browns among smaller samples.
D. Kerry, because most small bags will have more than 50% brown candies.
E. Both have the same chance because they are both random samples.

Figure 5. Item 5 – Understanding Role of Sample Size in Variability from Expected.

Discussion and Conclusions

Looking across the strengths and struggles of our teachers, two particular trends surfaced. First, teachers seemed to exhibit strong distributional reasoning when reasoning *from* graphs (items 4 and 14), but had difficulty predicting a graph of a distribution when given only statistical measures (item 3). Similarly, teachers were able to apply non-equiprobable approaches to a probability estimation task (item 7), but were prone to resort to applying equiprobable reasoning in a context about comparing likelihood of results from different sample sizes (item 5).

These results point to implications for us as course designers and for item and task development to measure our teachers' reasoning more systematically. First, we want to be sure to include a stronger focus in our courses for teachers to reason from graphical representations of distributions, as

well as towards predicting graphs of data with certain statistical characteristics. We also need to draw teachers' attention to students' use of equiprobable reasoning and how it can interfere with probability judgments. Such course improvements can include more targeted readings and discussions, as well as purposeful task design, particularly with technology tools. Our results also point to a need for multiple choice items and open response tasks that may better assess teachers' (a) reasoning from and to graphs of data, and (b) ability to apply equiprobable reasoning appropriately. With our focus on using dynamic statistics software, we aim to develop new assessment tasks and items that take advantage of these tools.

HIGH SCHOOL MATHEMATICS TEACHERS' STATISTICAL QUESTION POSING

Tyler Pulis
North Carolina State University
hpulis@ncsu.edu

Hollylynne S. Lee
North Carolina State University
hollylynne@ncsu.edu

The purpose of this study was to examine high school mathematics teachers' statistical question posing when engaged in statistical investigations in a graduate level mathematics education course. Sixteen teachers completed tasks at the beginning and end of a course on teaching and learning statistics in which they were asked to propose several questions that could be answered with multivariate data sets. In the course, teachers were provided opportunities to receive and provide feedback on statistical question posing. Analysis of the questions posed indicated that teachers asked many deterministic, computational questions, primarily univariate in nature, at the beginning of the course. On the final task, they asked no computation-only questions and many more broad and contextual questions, usually bivariate in nature.

Keywords: Data Analysis and Statistics, Teacher Education-Inservice, Teacher Knowledge

Introduction

New school mathematics standards have increased the focus on statistics and data analysis (Common Core State Standards Initiative, 2010), with research calling for an emphasis at the secondary level on statistical investigations (Franklin et al., 2007; Wild & Pfannkuch, 1999). The beginning of a statistical investigation includes choosing a focus and creating questions you will attempt to answer by collecting and analyzing data. Thus, statistical question posing is an important skill for both students and teachers engaging in statistical investigations (Arnold, 2008). In addition, as Arnold's (2008) review of other studies indicates, it is a skill with which both groups have difficulties. Lee et al. (under review) propose that teachers need to be asked to investigate and learn how to ask broader statistical questions. Statistical questions have been described in literature as distinct from mathematical questions in that they are contextual in nature and nondeterministic (Franklin et al., 2007). Makar and Fielding-Wells (2011) add that statistical questions should be ill-structured and ambiguous as opposed to the typical well-defined problems typically given in school mathematics. The purpose of this study is to examine the types of statistical questions that teachers posed about multivariate data sets at the beginning and end of a graduate level course on teaching and learning statistics.

Theoretical Background

It is important to consider statistical questions not just as the initial phase of an investigation, but as Konold and Higgins (2003) describe, as part of a back-and-forth process between data and researcher in which new questions may emerge. Several researchers have created classification schemes to differentiate types of statistical questions. Arnold (2008) defined statistical questions as summary, comparison, or relationship questions. Summary questions are usually about a single data set and serve to describe the data in some way. Comparison questions are used to compare a single variable across two or more subsets of data. Relationship questions are used to explore possible connections between two data sets. Lee et al. (under review) proposed distinguishing between broad and precise questions, where precise questions "focused on a specific goal or hypothesis, which could involve simple or complex analysis" and broad

questions required “a more open problem-solving process and perhaps more exploratory data analysis” (Table 3, p. 7).

Methods

This paper reports on sixteen teachers’ responses to an initial and a final task assigned in a graduate level class focused on teaching and learning statistics. For several weeks in the course, teachers had experiences aimed at assisting them in learning to pose statistical questions with given data sets. The participants consisted of two preservice teachers enrolled in an M.A.T. program; eight teachers in a masters program with six currently teaching (3 of whom taught AP Statistics) and two in graduate school full-time; six PhD students in Mathematics Education, all of whom had recent secondary teaching experience; and one Statistics PhD student currently teaching a college-level introductory statistics course. Twelve teachers were female and four were male. All teachers had completed an equivalent of an undergraduate degree in mathematics or statistics and all had taken at least the first level graduate course in statistics for social science majors (content about equivalent to Advanced Placement Statistics).

Tasks for Assessment

Two parallel tasks were used for the purpose of assessing teachers’ ability to pose statistical questions from a given multivariate data set and to use technology tools to explore and answer their question of interest. The initial task, given in the first week of the semester, was modified from Connected Mathematics: Data about Us (p. 40). Teachers were given data about sixth grade students’ jump roping that included three variables, two of which were categorical (class and gender) and one quantitative (number of consecutive jump ropes). Teachers were asked to “Generate several possible questions that could be answered with this data.” After generating questions, teachers were instructed to explore one of the questions (either by hand or using a technological tool), describe their exploration and findings, and note any new questions that arose as they explored the data. They were provided with data files for Excel, TinkerPlots, and Fathom. Most teachers had been exposed to these technologies in earlier courses.

The final task, given in the last week of the semester, asked teachers to generate possible questions that could be answered with a new data set. The task was parallel in structure to the initial task and provided a quantitative variable (students’ scores on the PSAT math section), as well as two categorical variables (grade level, and class). We note that there were three non-native English speakers in the class for whom the context of the PSAT was unfamiliar and information was provided on the possible range of scores for the PSAT math section.

Tasks for Learning

Upon examining the results of the initial task, the researchers (who were the course instructors) determined that more time needed to be spent on distinguishing statistical from deterministic questions. In the second week, teachers discussed differences between statistical and mathematical thinking and analyzed tasks for their potential to promote statistical reasoning. In the third week, teachers used TinkerPlots and discussed how its use could enhance their exploration of the initial Jump Rope task. Then, teachers examined the Census at School project’s questions and measurement guide (http://www.amstat.org/censusatschool/). Teachers downloaded random samples of 100 cases from the project’s respondent database and during the fourth week formed groups and proposed statistical questions to explore with the data. Each group provided feedback on another group’s questions and then revised their own questions.

Teachers struggled with posing statistical questions during these activities; therefore, teachers and instructors jointly developed a list of guidelines to consider. It was suggested that

questions should: invite multiple graphs and/or measures; provide room to explore other questions of interest; directly relate to context; consider why someone would care about the answer to the question and/or find the question interesting. In addition, teachers cautioned against posing questions with one answer or interpretation; pointing to specific measures or procedures in their questions; and forgetting about context. These guidelines match nicely with the recommendations of Makar and Fielding-Wells (2011) that statistical questions be interesting, challenging, and relevant; statistical in nature; and ill-structured and ambiguous. In other words, the questions should be answered through gathering and interpreting data and the wording of the question should require interpretation and negotiation among students.

Codes

All questions posed on the initial task and the final task were blinded and compiled into two new documents. Though we began by initially coding questions as broad or precise according to Lee et al. (under review), our analysis quickly emerged into a constant comparative method (Strauss & Corbin, 1990). In categorizing the questions, clear differences emerged among the types of questions coded as precise. Thus, new categories of codes emerged as we examined similarities and differences among the questions posed. For example, some questions only required looking at the data to find an answer. More complex precise questions involved computing a measure and comparing across groups or computing different measures for a single group and comparing the differences between the measures. Descriptions and examples of the codes generated are provided in Table 1.

Table 1: Question Codes

Code	Definition	Examples from Teachers' Work
Look at Data	Looking for special cases in the data.	Did a boy or girl have the most jumps?
Compute	Compute a specific measure on one subset of the data.	What is the mean of consecutive jump ropes in Mrs. A's class?
Compute and Compare	Compute a specific measure or measures and compare between two subsets of data.	What is the difference between the mean number of jumps for the girls in Mrs. A's class and the mean number of jumps for the girls in Mrs. B's class?
Display and Describe	Visually display the data and describe it.	Construct a box and whisker plot. Are there any outliers?
Broad	Invite exploration of data; do not point to a specific measure or method.	Which class seems to be better at jumping rope?
Contextual	Refer back to context; may not be answerable by data.	What might these values imply about the genders?
Inappropriate	Inappropriate/nonsensical statistical question	What is the mean and median of the number of girls in both classes?

Findings

The most dramatic difference between the types of questions posed by teachers on the initial and final task related to the Compute category. On the initial task, this was the most frequently posed type of question. In contrast, on the final task, no questions of this type were posed by any of the teachers. The number of Look at Data questions also decreased from twelve to two. Other differences were the increase in questions coded Broad or Contextual on the final task compared

to the initial task. It is worth noting that 14 out of the 16 teachers were able to compose broad questions on the initial task, but the tendency was to ask more Compute questions.

Table 2: Results

	Initial Task		Final Task	
Code	**# of questions posed**	**# of teachers posing**	**# of questions posed**	**# of teachers posing**
Look at Data	12	5	2	2
Compute	69	11	0	0
Compute and Compare	32	11	11	6
Display and Describe	5	1	0	0
Broad	32	14	58	16
Contextual	8	2	16	9
Inappropriate	7	2	5	3

Conclusion & Summary

This study examined the nature of questions posed by teachers at the beginning and end of a graduate level course on teaching and learning statistics. It is apparent there was a change in the types of statistical questions posed by these teachers between the initial and final tasks. While both of these tasks involved posing questions from given data, we acknowledge that it is also important for teachers to learn to design instruments and collect their own data. Given the time consuming nature of engaging in the entire statistical cycle, it seems advantageous to improve teachers' skill in posing questions related to existing data. It is possible that learning to pose statistical questions from data might also create better understanding of the connections between research questions and data collection measures. Further research is warranted to determine which learning experiences in the course contributed to the change in questions posed and to consider implications for changes in the teachers' instructional practices.

LEVELS OF REASONING FOR UNDERSTANDING THE CONCEPT OF PROBABILITY

Julio C. Valdez
CINVESTAV-IPN
jvaldez@cinvestav.mx

Ernesto Sánchez
CINVESTAV-IPN
esanchez@cinvestav.mx

The purpose of this work is to describe the evolution of the reasoning of a high-school student on the concept of probability from the inferences he is able to make with this concept. Based on Jones' framework which describes probabilistic reasoning, excerpts from interviews are analyzed in which important characteristics of the student's reasoning are revealed. It is shown that the difficulties the student faced in different moments are: giving meaning to random quantification, overcoming the law of small numbers, and managing variation in a convenient way. It is observed that two important elements to overcome these difficulties are: an informal knowledge of the law of large numbers and reasoning with relative quantities. The work concludes with a hierarchy that describes the probabilistic reasoning of this student.

Keywords: High School Education, Probability, Technology.

Introduction

The level of understanding a subject reaches on a concept is associated with the meaningful and plausible inferences he is capable of formulating with it. Concerning the concept of probability, the most important inferences are "the *unpredictability* of random phenomenon in the short-run [and] *predictability* in the long-run trends in data (i.e., the law of large numbers)" (Sthol & Tarr, 2002). In order to formulate such inferences it is necessary to make both the frequency and classic approaches of probability intervene and articulate. To elucidate this process of (inferential) articulating, the framework proposed by Jones, Thornton, Langrall and Tarr (1999) is suggestive since it shows a wide description of probabilistic reasoning and its interconnections. However, there are two important modifications made in the present work regarding this framework: 1) only one subject is studied and 2) the subject is older than those examined by Jones. As a consequence, the following question arises: How is the evolution of a high-school student's reasoning on the concept of probability according to what Jones' framework establishes?

Conceptual Framework

Jones *et al.* (1999) propose a framework that describe and predict students' probabilistic reasoning (8-14 years old) based on four levels: *Subjective*, associated with a idiosyncratic or non-quantitative reasoning; *Transitional*, it begins to recognize the significance of quantitative measures, but frequently there are regressions; *Informal Quantitative*, it involve quantitative reasoning of the form "more of", "less of", "3 out of 5"; *Numerical*, incorporate reasoning with relative numbers and its operations. The authors analyze probabilistic reasoning through six constructs: *sample space*, *experimental probability*, *theoretical probability*, *probability comparisons*, *conditional probability*, and *independence*. Notwithstanding, in this work we regard the fourth ones, because of they are enough to account for the reasoning about the concept of probability of student studied here.

Methodology

This work is a case study that follows up the evolution of the reasoning on the concept of probability in one single student. He studied the third year of high-school (17 years old) and had a good arithmetic and algebraic reasoning, though he had never studied any probability topics. Only one student was considered in order to explore the underlying ideas between classic probability and relative frequency in a deeper way, and his age was determined because such ideas have a complexity which is not easy to handle by younger students (Ireland & Watson, 2009; Konold, Madden, Pollatsek, Pfannkuch, Wild, Ziedins, Finzer, Horton & Kazak, 2011). Fifteen one-hour long interviews were conducted. In two of them the problem in Figure 1 was developed including its simulation using the Fathom software. Both sessions were videotaped, transcript, and analyzed.

In box A there are 3 black chips and 1 white chip. In box B there are 6 black chips and 2 white ones (fig.1).

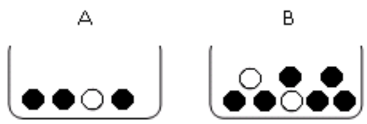

fig. 1

A box is chosen and a chip is drawn randomly from it. A prize is won if it is a black one. Juan considers that choosing box B is the most convenient action because no matter both boxes have a proportional quantity of black and white chips there is a larger number of black chips in B.

a) What do you think about Juan's explanation?
b) How would you measure the possibility that the event "drawing a black chip from box A" occurs? Which value would you assign to it?
c) How would you measure the possibility that the event "drawing a black chip from box B" occurs? Which value would you assign to it?
d) How would you prove the answer given in a)?

Figure 1: Probability Comparison Problem

Results

First episode. Miguel wrongly believes that Juan's statement in the problem is right and answers: "I think it is better [to choose box B] because of the [greater] number [of black chips when compared with box A]". Later, he is asked: Which value would you assign to the possibility of drawing a black chip from box A? In his answer, he questions the meaning itself of the assignation: "What do you mean a value?... that's what I don't understand, which value. They are values of what or what…". After a brief intervention of the interviewer, the student shows he perceives the equality in the proportions of black chips: he says there is a "75% of drawing a black [chip from box A]" and a "75% [of drawing a black chip from box B]". However, despite he has apparently calculated the probability of drawing a black chip from each box and observed they are equal, he maintains his appraisal on the situation: "I think Juan is right". As a consequence, this reasoning is placed in a *Subjective* level (Jones *et al.*, 1999).

Second episode. Now, Miguel is asked to draw randomly samples of size 10 with replacement from box A (with one white chip and three black ones) and another one from box B (with two white chips and six black ones), and to register the results in Table 1.

Table 1: Results From the 10 Extractions in Each Box (B = white chip and N = black chip)

Number of drawings	1	2	3	4	5	6	7	8	9	10
Box A	N	N	N	N	N	N	B	B	N	N
Box B	B	N	N	N	B	N	N	N	N	N

Based on these results, Miguel was asked: Which box would you choose if you wanted to get a black chip? He answers he would pick box A and explains: "the first chips drawn turned out to be black". Then, he is asked to draw other samples of size 10, one from box A and another from B. He obtains ten and seven black chips respectively, which strengthens his belief. He is asked now to predict the frequency of white and black chips in 100 and 1000 possible repetitions of the experiment in each of the boxes (Tables 2 and 3).

Table 2: Prediction of the distribution of 100 extractions

Error! Objects cannot be created from editing field codes.

Table 3: Prediction of the distribution of 1000 extractions

Error! Objects cannot be created from editing field codes.

Miguel's predictions as well as his assignation of values 80% and 70% respectively to the possibility of drawing a black chip from boxes A and B reflect his wrong belief that there are more possibilities of getting a black chip from box A. It is convenient to note that this reasoning is based on a bias called the *law of small numbers* (Tversky & Kahneman, 1982). However, Miguel has set in play the necessary elements that constitute the basic frame of probability: the proportions of chips in the boxes and the relative frequencies; but he has not articulated them yet in a convenient way. Therefore, his reasoning is at a *Transitional* level (Jones *et al.*, 1999).

Third episode. Afterwards, Miguel is asked to represent the situation in the Fathom software and to make the corresponding simulations in which he obtains the following results:

Table 4: Results of the computer simulation of 100 extractions

Error! Objects cannot be created from editing field codes.

Table 5: Results of the computer simulation of 1000 extractions

Error! Objects cannot be created from editing field codes.

When asked what he observes, Miguel focuses his attention in circumstantial characteristics (Table 4): "The more black chips [are in the boxes] […] the less [black chips] are [in the simulation]". Later on, as a result of the interviewer's questions on the cases of 100 (Table 4), 1000 (Table 5) and 10,000 (represented in the software) drawings, Miguel focuses his attention in the similarity that exist between the relative frequency of black and white chips obtained in the simulation and the proportion of black and white chips in the box. Besides, he observes that this similarity grows closer as the number of trials increases. Nevertheless, he considers box A offers a greater possibility of drawing a black chip since he reasons with absolute numbers caused he values the differences between results as meaningful: "Black chips come out more often from box A than box B. Here [Table 5] […] there are two [chips] less, but here [Table 4] […] there are six times more". It's evident that the Miguel´s observation that box A offers a greater possibility of drawing black chips turned out a relatively strong belief because, in absolute terms, this situation was favored by the results in the physical and computer simulations. Thus, his reasoning remains in the *Transitional* level (Jones *et al.*, 1999).

Fourth episode. Miguel assigns the values 77% and 71% to the possibility of drawing a black chip from boxes A and B respectively, reasserting what happened in the *third episode*. This assignation is only supported by the results of 100 drawings (Table 4), so the interviewer questions the student so that he assesses how appropriate these values are to the other cases of 1,000 (Table 5) and 10,000 drawings. As a consequence, Miguel integrates two observations he had made during the *third episode* into his reasoning; on one hand, that the relative frequency of black and white chips obtained through simulation is similar to the proportion of black and white chips in the box; on the other hand, that this similarity grows closer as the number of trials increases: "it is almost a quarter of white chips and three quarters of black chips in 10,000… They are the same, no matter the box [which one choosing]". He assigns the appropriate values to these possibilities at the same time: "75%". So, his reasoning has now reached the *Informal Quantitative* level (Jones *et al.*, 1999).

Conclusions

Through the interviews, Miguel´s reasoning regarding probability goes from the *Subjective* to the *Informal Quantitative* level, preparing him to the *Numerical* level. Based on these results, we then proposed as a conclusion a hierarchy that describes the reasoning of this student on the concept of probability. This hierarchy integrates the levels proposed by Jones *et al.*, (1999): *Subjective*, in which no meaning is attributed to the assignment of a number to an event, or a number is assigned in a naïve way without the possibility to make inferences; *Transitional,* in which a number is assigned to an event in an intuitive way based on the analysis of the random device (v.gr. the contents of color chips in the boxes) or on the relative frequencies, but without adequately relating them, which prevents the formulation of pertinent inferences; *Informal Quantitative,* in which the frequency and classic approach are used to assign a number and some relationship among subjective assignment, analysis of the random device and frequencies are perceived; in this way inferences start to be created, but there is no reasoning with relative numbers, so variability is not assimilated; *Numerical*, in which both approaches are set in play to assign a number to an event and relationships among subjective assignment, analysis of the random device and frequencies are perceived. Particularly, there is reasoning with relative numbers to adequately consider the variability and, in consequence to make better inferences.

STATISTICAL REASONING DEVELOPED BY UNIVERSITY STUDENTS EXPLORING DATA IN A COMPUTER ENVIRONMENT

Santiago Inzunsa Cazares
Autonomous University of Sinaloa
sinzunza@uas.edu.mx

The Problem

Lajoie & Romberg (1998) identify as an important task to the development of reasoning and statistical thinking in high school students, formulating research questions and following through with data creation, collection and interpretation. In this sense, we established the following research questions: what types of representations and software resources the students use to the answering of the questions about a data collection? Have they employed all the potential of the representations that the software provides for the data analysis? How is characterized the statistical reasoning developed by the students in the exploratory data approach through the use of the technology?

The theoretical perspective adopted firstly considers, from a point o view of an expert in statistics who requires formulate questions about the collection of data, by implicating a set of knowledge and abilities to make sense to the complex relationships and information expressed in some graphics and descriptive tables with statistical summaries. Secondly we considered that the use of computer technology in the data analysis not only represents an amplifier resource of the computing capacity and construction of the graphical representations but constitutes at the same time a resource with potential of reorganization of the mental activity of the users.

The research involved 34 first grade university students of the computers science program (between 18-19 years old) while taking the probability and statistics course. The research was carry out while addressing topics of data analysis that are contemplated in the curriculum focusing to the use of an explorative approach with the dynamic software Fathom (Finzer 2000). The final activity in the study consisted of a collection of data of automobiles on sale in Mexico.

Conclusions

In general the students utilized the previewed representations and it was observed correct analysis, but not enough from the point of view of an expert, since in the interpretations there not always were utilized all the information given by the representations that they built. It is conjecture that their statistical knowledge was not enough to make a more complete interpretation. Even students utilized with frequency more than one representation (graphics and summary tables) their interpretations were based most of the times on the identification of descriptive measures provided by the tables. The results shown that the global comprehension of the data is a difficult aspect to many of the students, however the plenty information of the representations that they utilized, it is located over the frequency showed with a local approach of the data and its interpretations. In this manner their statistical reasoning was correct but incomplete in most of the cases, for it is required a high level of knowledge of the concepts of data analysis to give sense to the information provided by the diversity of the representations provided by software as the one utilized in this research.

INDIVIDUAL DIFFERENCES IN CALCULATING POSTERIOR PROBABILITY: DO STATISTICS EDUCATION AND MATH PROFICIENCY MATTER?

Virginia Clinton
University of Wisconsin
vclinton@wisc.edu

Martha W. Alibali
University of Wisconsin
mwalibali@wisc.edu

Mitchell J. Nathan
University of Wisconsin
mnathan@wisc.edu

Educators may be interested in the factors that are associated with probabilistic reasoning so that they can better understand the needs of their students. The purpose of this study is to examine individual differences that may predict success in solving a posterior probability problem, specifically prior statistics education and math proficiency. Previous research findings on these relations have been mixed, and they differ depending on the type of reasoning involved. As one might expect, statistics education is often associated with better performance on probabilistic reasoning tasks (Fischbein & Schnarch, 1997). However, statistics education is associated with an increase in the misconception that all events are equally probable (i.e., equiprobability bias), perhaps due to the emphasis on randomness in statistics education (Morsanyi et al., 2009). Focusing on the randomness of an event occurring, without considering other factors that affect probability, may increase the equiprobability bias. There are also mixed findings regarding relations between math proficiency and performance on probabilistic reasoning tasks (e.g., Johnson & Kuennen, 2006; Stanovich & West, 1998). For example, Stanovich and West (1998) found that SAT math scores were positively associated with being able to identify important information in a posterior probability problem, although this did not result in improved accuracy in posterior probability problem solving.

Undergraduate students ($N = 210$) were given a posterior probability problem to solve and provided self-reports of their statistics education and standardized math test scores (ACT or SAT). Approximately 20% of the students solved the problem correctly. Students who answered the problem correctly ($M = .59$, $SD = .55$) tended to have taken more statistics courses than those who solved the problem incorrectly ($M = .37$, $SD = .50$), Exp(B) = 2.25, $p = .02$. In addition, students who solved the problem correctly reported ACT or SAT scores in higher percentiles ($M = 94.76$, $SD = 4.80$) than those who solved the problem incorrectly ($M = 89.54$, $SD = 11.16$), Exp(B) = 1.09, $p = .01$. These findings suggest that for student populations with weak mathematics skills or with little statistics background (e.g., introductory statistics students), posterior probability problems may require special attention.

MISTAKES IN DRAWING THE SHAPE OF A DISTRIBUTION BY MIDDLE SCHOOL STUDENTS

Joshua Michael Goss
Western Michigan University
joshua.m.goss@wmich.edu

Feng-Chiu Tsai-Goss
Western Michigan University
feng-chiu.tsai@wmich.edu

The Common Core State Standards for Mathematics (National Governors Association Center for Best Practices Council of Chief State School Officers, 2010) includes studying the shape of a distribution as a statistical topic for middle school students. Shape is a fundamental idea for understanding the concept of distribution and provides an organizing structure to conceive data as an aggregate entity instead of individual values (Bakker & Gravemeijer, 2004; Reading & Canada, 2012).

Drawing graphs to predict the shape of a distribution in hypothetical situations, namely without having data, is a useful instructional design to foster students' understanding of shape and distribution (Bakker et al., 2004). Zieffler, Garfield, Delmas, and Reading (2008) also suggest having students draw a graph of a population based on a sample to promote their reasoning about the shape of the population. This implies that experience drawing graphs might have an influence on students' reasoning about the shape of a distribution. Thus, there is a need to understand more about the graphs students draw to predict the shape of a distribution. To better understand students' drawing of distributions, this study investigates the following research question: *What mistakes do 6th graders make when asked to draw a shape for an unknown population based on a sample?*

This work is part of a larger study investigating middle school students' informal inferential reasoning. Four 6th graders of varying mathematics achievement levels participated in the study. A paper-pencil test was administered, followed by an interview to gain a deeper understanding of students' thinking in answering the questions. The test includes two problems, along with two sub-questions each. Each problem required participating students to draw a shape for the population based on a given sample. The results illustrate the misconceptions that surfaced in their graphs of unknown populations based off of small samples. Implications for analyzing and learning from students' thinking in drawing shapes will be presented.

THE LINEAR LOGISTIC TEST MODEL AND MODELING CONCEPTUAL UNDERSTANDING IN MATHEMATICS ASSESSMENT

MacDonald, G.
University of South Florida
gmacdona@mail.usf.edu

In the report, Adding it Up: Helping Children Learn Mathematics, the Mathematics Learning Committee from the National Research Council (Kilpatrick, Swafford, & Findell, 2001) suggested that student learning and performance could be enhanced if conceptual understanding was taught at the same time as procedural fluency. This major new direction placed a great emphasis on the idea of conceptual understanding as a main strand within mathematics education. Cognitive diagnostic assessment (CDA) is an important thrust in measurement designed to assess students' cognitive knowledge structures and processing skills in relation to item difficulty (Leighton & Gierl, 2007). There has been an increasing demand in education to develop assessments that map and measure the psychological processes involved in conceptual understanding. Fischer (1973) introduced a model, called the linear logistic test model (LLTM) that is capable of bridging cognitive processing models and psychometric models.

The purpose of this study is to provide some evidence to help determine if the LLTM functions well and is robust when the Q-matrix is properly specified, underspecified, balanced misspecified, and overspecified. A simulation study was conducted to explore the performance of the linear logistic test model (LLTM) when the relationships between items and cognitive components were misspecified. Marginal maximum likelihood and empirical Bayes were used in SAS to estimate parameters for cognitive components and item difficulty, as well as person ability, respectively. Factors manipulated in the simulation study included overall type of misspecification (under-, balanced-, and over-specification), percent misspecified (1%, 5%, 10%, and 15%), sample size (20, 40, 80, 160, 320, 640, and 1280), Q-matrix density (64% and 46%), skewness of ability distribution (-0.5, 0, and 0.5), and test length (20, 40, and 60 items). Statistical bias, RMSE, CI coverage, and CI width were computed for estimates across the set of replications.

As the Q-Matrix moved away from the truth, cognitive components and item difficulty estimates became progressively more biased (positive bias with under-specification, and negative bias for balanced- and over-specification). Results were interpreted for the design factors and recommendations for the application of LLTM in assessment studies were provided.

HOW CAN MATHEMATICS EDUCATORS FOSTER HIGH SCHOOL STUDENTS' RISK LITERACY?

Nenad Radakovic
University of Toronto
nenad.radakovic@utoronto.ca

The purpose of the study is to investigate high school students' understanding of risk with respect to the coordination between likelihood and impact. The objectives are: 1) to investigate students' informal knowledge of risk and their informal coordination between likelihood and impact; 2) to explore ways in which the formal instruction can foster the coordination between likelihood and impact. In this study, risk of an event is defined as the measure of both likelihood and impact (Pratt, et al., 2011). The study is a case study of teaching risk literacy in Ontario in a grade eleven enriched classroom during the probability and statistics unit (23 participants, 19 girls and 4 boys).

Based on the initial assessment, students were divided in five groups and given an activity in which they had to assess the safety of nuclear power plants using data including likelihood and impact. In the second part of the activity, students were asked to estimate an impact of an accident based on empirical data provided. The students were then asked to assess the risk of both nuclear and coal accident by combining the data on probability and impact. The coordination was initially presented to the students as the product of probability and impact. After this, the students were provided the set of coordinates with the probability on the vertical axis and the impact on the horizontal axis. The students were then asked to plot the values for the probability and impact for both nuclear power plants and coal power plants.

Three themes emerge from the research: informal knowledge about impact, the role of content knowledge, and the role of critical elements. There is evidence that students possess pre-existing informal (intuitive) knowledge of impact. From pedagogical viewpoint, this fact is encouraging since in many other domains (such as assessment of probability) there is strong evidence that individuals' intuitions are often erroneous. As it was seen from the intervention, this informal knowledge has a potential to be used in the instruction.

The initial assessment in both classrooms shows that students use different language to talk about impact (e.g., "massive" and "dangerous"). Through the introduction of quantitative data, the informal qualitative descriptions can be transformed into quantitative in order to make descriptions more formal and ready to use in the mathematical analysis. For example, the word "massive" can be transformed into a numerical value consistent with the statistics presented in the activity. Students' responses suggest that at least some of them have used their own personal knowledge about energy sources to answer the question. This is consistent with Pratt et al.'s (2011) view that the coordination between likelihood and impact has to be viewed in conjunction with students' personal beliefs and values. Data suggest that the coordination between likelihood and impact has to be taken into account together with critical elements. Students would benefit from being aware of the "worry questions" (Gal, 2005) such as the nature of the terms used in statistical inference as well as being aware of where data came from. For example, some students did question the meaning of "significant" in the statement that there were only three "significant" accidents. However, many students ignored the term and concentrated on the numerical information alone.

CAPTURING EARLY ELEMENTARY SCHOOL STUDENTS' INFORMAL INFERENTIAL REASONING THROUGH STORYTELLING

Dustin Owen Smith
Western Michigan University
dustin.o.smith@wmich.edu

The importance of developing statistical literacy in schools is advocated by numerous researchers (e.g. Shaughnessy, 2007; English, 2012; Pfannkuch, 2011, Makar & Rubin, 2009). One growing area of research on statistical learning centers on Informal Inferential Reasoning (IIR). Makar and Rubin (2009) describe IIR as having three components: expressing uncertainty, making and evaluating claims, and drawing explicitly from the data when making or evaluating claims. There is limited research about IIR at the early levels of elementary school but this type of informal reasoning can be a powerful precursor to formal statistical learning in the middle grades (English, 2012). This poster details the results of a study that focused on providing opportunities for young children to make informal inferences about data through an approach called Storytelling-Questioning. The goal of Storytelling-Questioning was to provide young students with fruitful opportunities to engage in IIR within the context of the normal classroom practice of listening to stories. Storytelling-Questioning consists of the researcher reading students a story, and asking strategic questions both planned and unplanned, that are grounded in the story's context and content, and built on the students' responses. This work represents a new use for stories (given its focus on IIR) and builds off recent interest in using storytelling in mathematics (e.g. van den Heuvel-Panhuizen, van den Boogaard, & Doig, 2009).

Four groups of three students (half from kindergarten and half from 2nd grade), participated in the Storytelling-Questioning episodes. The goal of this research was to answer the question, *What information about early elementary school students' Informal Inferential Reasoning does Storytelling-Questioning elicit?* The results of this research speak to the affordances of eliciting IIR through questioning during storytelling. The results demonstrate that Storytelling-Questioning approach provided ample opportunities for students to engage in IIR. Stories proved a natural avenue for students to make and evaluate predictions based on data in the story. Expressing uncertainty about a claim given that the sample data presented is on aspect of IIR. Stories provided a context in which students were able to acknowledge some elementary ideas of variability by expressing uncertainty. The story and the expressions of uncertainty tied closely together. The story seemed to facilitate students' recognition of the uncertain nature of predictions based on a sample. In addition to these results, this poster will also reflect the ways in which Storytelling-Questioning might be improved to become a more efficient method of engaging young students in this crucial type of statistical reasoning.

A FRAMEWORK FOR STUDYING SECONDARY MATHEMATICS TEACHERS' AFFECT TOWARDS STATISTICS

Christina Zumbrun
Trine University
zumbrunc@trine.edu

Secondary mathematics teachers' affect (emotions, attitudes, and beliefs) towards statistics is an important construct in light of the increasing importance of statistics in the school curriculum (McLeod, 1992; Shaughnessy, 2007). A characterization of this population's affect regarding statistics requires careful consideration of relevant factors such as teachers' knowledge, experience, identity, views of statistics and mathematics, and conceptions related to the teaching and learning of mathematics and statistics. The proposed framework for studying secondary mathematics teachers' affect towards statistics is part of a study whose fundamental purpose is to analyze and describe secondary mathematics teachers' emotions, attitudes, and beliefs towards statistics. The framework for the study establishes the research domain as the *affect system*, which is primarily comprised of emotions, attitudes, and beliefs towards statistics. The designation *affect system* has been adopted for the study since this population of teachers' emotions, attitudes, and beliefs are heavily influenced by knowledge, experience, identity, conceptions, and curriculum. Therefore, *affect system* refers to the complete organization of interworking parts that define secondary mathematics teachers' emotions, attitudes, and beliefs towards statistics. The larger framework of the proposed *affect system* establishes three general categories: emotions, attitudes, and beliefs. The three general categories are then divided into smaller categories. For instance, emotions are set apart from attitudes and beliefs by a strong relationship with context (mathematical and statistical); in light of this, local affect versus global affect will be explored. Teachers' feelings associated with mathematical intimacy and integrity within a statistical context will also be studied as an aspect of emotion. Attitudes will be distinguished from emotions by their categorization as automatized emotions that have become more stable over time (Phillip, 2007). Attitudes are conceptualized through teacher identity, including identities pertaining to self, mathematics, teaching mathematics, statistics, learning statistics, teaching statistics, and social contexts. While attitudes and beliefs are separate constructs (McLeod, 1992; Phillip, 2007), they are necessarily connected. The conception of teacher identity described as part of attitude impacts teacher knowledge and experience, which are elements of beliefs in the proposed framework. Within the construct of beliefs, knowledge and experience impact conceptions, which potentially influence teacher practice. Through their practice, teachers develop and respond to beliefs about the curriculum related to mathematics and statistics. This strengthens the proposed connection between teaching practice and conceptions.

STUDENTS' CONCEPT IMAGES OF AVERAGE RATE OF CHANGE

Allison Dorko
Oregon State University
dorkoa@onid.orst.edu

Eric Weber
Oregon State University
Eric.Weber@oregonstate.edu

In this paper, we describe students' concept images of average and average rate of change and the similarities and differences between those concept images. We do so by describing the students' ways of thinking and ways of understanding average and average rate of change, and how the students' meanings for average influenced their conceptions of average and instantaneous rates of change. We describe the importance of everyday meanings for average in students' conceptions of rate, and propose how instruction might be tailored to address this link. We conclude by discussing implications of this work for teaching average and instantaneous rates of change in single and multivariable calculus, and suggest important directions for future research.

Keywords: Advanced Mathematical Thinking, Cognition, Cognition, Learning Trajectories (or Progressions)

Introduction

The purpose of this paper is to explain how students leverage their understanding of average in their conception of average rate of change in differential and multivariable calculus and the implications of that leveraging for ideas that rely on a concept of average. Rate of change is foundational to calculus because it allows a student to represent how fast a quantity changes with respect to one or more other quantities. While average rate of change has a specific mathematical meaning in calculus, the word *average* may have lexical ambiguity because of its use in statistics and everyday language (Barwell, 2005). We hypothesized that students' understanding of average created confusion as they learned about average rate of change in calculus, and that they developed meanings for average rate of change that relied on an everyday understanding of the word average. We sought to characterize what students' concept images for average rate of change by focusing on their ways of thinking about average and their subsequent ways of thinking about average and instantaneous rate of change. We use *ways of thinking* as Harel and Koichu (2010) do to mean "a cognitive characteristic of a person's ways of understanding associated with a particular mental act" (Harel & Koichu, 2010, p. 117). In this paper, we describe the theoretical underpinnings of the study, identify how our assumptions about student thinking drove the study's design, illustrate our methodology and coding, and present a framework that characterizes students' concept images of average and average rate of change. We argue that specifically addressing the different uses of average in mathematics, statistics, and everyday language is crucial to students developing a coherent understanding of average and instantaneous rate of change in calculus and propose ideas for helping students develop the conceptions of average and instantaneous rate of change that we intend.

Theoretical Framework

In this study, we focused on representing students' understanding and thinking, which by their nature are models that are shaped by our inferences based on students' actions and words. This study relied on the assumption that ways of thinking and ways of understanding (Harel &

Koichu, 2010) reside and develop at the level of the individual and reveal themselves in the decisions and actions students undertake.

Given our assumptions about learning and thinking, we used Vinner's (1983) definition of *concept images* as an orienting framework because students' understandings of average were largely imagistic in nature. We drew on Vinner's (1983) definition of *concept image* as the set of properties associated with a concept together with the all the mental pictures the student has ever associated with the concept. Vinner (1983) differentiates between the concept image and the concept definition (the verbal definition typically used to introduce a concept) and proposes that while handling a concept requires both image and definition, "in thinking, almost always the concept image will be evoked" (p.293). That is, while engaging in mathematical thinking, students tend to use their mental pictures of a concept rather than a symbolic or verbal definition.

We analyzed students' concept images for average and average rate of change. We looked for and asked specifically about similarities in how *average* was used in find-the-mean computational problems and in questions about two- and three-variable functions' average rates of change. We looked for students' *ways of understanding* both average and average rate of change and their *ways of thinking* about these two topics. We make the same distinction between *ways of understanding* and *ways of thinking* that Harel and Koichu (2010) do. That is, a *way of understanding* is the product of a mental act – a single moment as a student grapples with a mathematical situation, while a *way of thinking* "a cognitive characteristic of a person's ways of understanding associated with a particular mental act" (Harel & Koichu, 2010, p. 117). By 'characteristic,' Harel and Koichu mean a distinguishing trait. A *way of thinking* is a pattern of ways of understanding.

The result of analyzing students' concept images under the framework of *ways of understanding* and *ways of thinking* are descriptions of how students think about average and average rate of change, expressed imagistically as they are in students' minds.

Literature Review

Understanding rate of change is foundational to ways of thinking about ideas in calculus, yet many students possess difficulties reasoning about rate (Carlson et al., 2001; Rasmussen, 2000; Thompson & Silverman, 2008). Students' difficulties understanding rate of change include problems interpreting the derivative on a graph (Asiala et al., 1997) and focusing on cosmetic features of a graph (Ellis, 2009). Thompson (1994) found that the difficulties students displayed in understanding the fundamental theorem arose from impoverished concepts of rate of change and incoherent images of functional covariation. Thompson described a coherent way of thinking about average rate of change of a quantity as, "if a quantity were to grow in measure at a constant rate of change with respect to a uniformly changing quantity, then we would end up with the same amount of change in the dependent quantity as actually occurred"PAGE # ?. However, we observed that this way of understanding was difficult for students to achieve.

We hypothesized this difficulty with average rate of change could be attributed to meanings students associate with the word *average*. Students' meanings for words used in technical domains are connected to past experiences with the word (Lemke, 1990). *Average* is used both in everyday language and in mathematics and thus may have lexical ambiguity, or multiple meanings (Barwell, 2005). Meanings statistics students hold for *average* include "definitions that were not indicative of the center and…responses that were not obviously connected to the idea of average as a measure of center or what is typical" (Kaplan et al., 2009, p.11). Given these meanings for average and our hypotheses about students' use of average, we investigated

calculus students' meanings for average in the context of compute-the-mean tasks. We then had students complete average rate of change tasks to see if their meanings for average affected their understanding of average rate of change.

Method

Subjects and Setting

We recruited sixteen multivariable calculus students from a pool of volunteers from six sections of multivariable calculus. We chose this course because it was the students' first exposure to functions of more than one variable in mathematics. This allowed us to observe the students' initial fits and starts with systems with more than one quantity, and to adjust our subsequent questions to more clearly understand their thinking. Each student participated in a pre and post interview. The pre and post interviews questions were designed to gain insight into the students' ways of thinking about function and rate of change. The pre-interview questions were open-ended and focused on single-variable functions and rates. The post-interview questions were also open-ended and consisted of questions about both single and multivariable rates of change.

Analytical Method

Data analysis was multi-phased. We used the pre-interviews to characterize ways of thinking about and understanding function and rate of change. We identified common behaviors and responses across interviews using grounded theory (Corbin & Strauss, 2008) with a particular focus on students' concept images for average rate of change and instantaneous rate of change. Our analyses from the pre-interviews suggested that students relied on colloquial definitions of average in their representations of average rate of change, and that those definitions were prevalent in both two and three dimensions. We designed the post-interviews to gain insight into students' images for average, average rate of change, and their thoughts about how those uses of average were related. We identified and transcribed important passages that gave insight into students' concept images for average in its use in statistics and calculus. We identified a set of concept images for both average and average rate of change using open and axial coding (Figures 1 and 2).

Category	**Criteria**
Normal, typical, mediocre, common	Student uses the word 'normal,' 'mediocre,' 'typical,' or 'common' to describe 'average.'
Mean	Student uses the word 'mean' to describe 'average' or as a synonym for 'average'
Median, middle, center, balance point	Student uses the words 'median,' 'middle,' 'center,' or 'balance point' or talks about the average as being the middle or center of the data
Overall summary, representative value, value used to compare, estimate, expected value	Students talk about the average as a number that presents an overall summary of the data; a number that is representative of all the data; the average as an estimate/approximation or expected value for a new data point; or talk about using the average to compare data
Mode, most common number	Student uses the word 'mode' as synonymous for 'average' or talks about average as the most

	common number

Figure 1: Students' Concept Images for Average

Category	Criteria
Arithmetic mean of slopes	Student talks about summing slopes and dividing by number of slopes summed whether it is a finite or infinite number of slopes is irrelevant to the student.
Expected or most common slope	Student uses the word 'most common', 'expected', 'typical' to describe average rate of change. The student expects the average rate of change provides information about 'all' of the slopes.
Constant rate of change	Student describes average rate of change as the constant rate of change required to produce the same change in the function over the original interval of input.
Smoothing out of all the slopes	Student describes the average rate of change as the all of the slopes smoothed out. Student describes decreasing the 'choppiness' of the slopes.

Figure 2: Students' Concept Images for Average Rate of Change

Results

The following results are representative of our findings for the sixteen students. We highlight three students' responses that represent the major categories of thinking and understanding we identified. We found that students carry their meanings for average into their thinking about average rate of change. We will demonstrate this with excerpts from student responses to the tasks shown in Figure 3. The interviews included two additional compute-the-mean tasks similar to question 1 and two additional conceptual rate of change problems similar to questions 2 and 3.

Questions
(1) The data given below represent the masses of six fishing lures. What would the average mass of the lures mean?
(2) Suppose we define a function *f*, so that $f(x)=e^{-\cos(2^x)}$. Discuss the *process* you would use to determine the average rate of change of the function with respect to *x* over the interval [2.0, 2.2]. (3) Suppose we define a function f, so that $f(x,y)=e^{-\cos(xy)}$. Discuss the *process* you would use to determine the average rate of change of the function. What information do you need to know to complete this process?

Figure 3: Representative Interview Tasks

Responses across these tasks demonstrate the use of concept images for average in the concept images for average rate of change. For instance, Brian's concept image for average is one of 'smoothing out,' a phrase he used explicitly when talking about average rates of change (Response to 2). We also infer that Brian's use of average rate of change being a constant rate as related to the idea of smoothing out; that is, the constant rate is a smoothed-out number made from finding the mean of instantaneous rates (Response to 3). Jordan's concept image for average included the property that an average is a 'typical value' (Response to 1) and she correspondingly thought about average rate of change as a typical slope (Response to 2). Jane's concept image for average included the property of an average being 'common' (Response to 1) and she thought average rate of change as the most common value (Responses to 2 and 3).

Brian: [Response to 1] I see the average as kind of like adding everything up into a big ball, and then smoothing it out into equivalent pieces.

[Response to 2] I see the average rate of change like a constant rate of change. Like, how fast the function would need to change to produce the same change in y over the same change in x, but at a constant rate. You take the change in y over the change in x, that kind of smooths it out to determine it for you.

[Response to 3] Now, well, this is harder but I still know I am finding a constant rate of change. However, to pick a constant rate, you have to specify a direction in space, or there would be infinite average rates of change. So, you still have a change in the function on top, but divided by a change one variable or the other. It tells you a constant rate of change.

Jordan: [Response to 1] Well, I sum the masses, then divide by how many there are, which tells me what their mass was mostly, or typically.

[Response to 2] Well, I am finding the slope between two points here Right, so I find the change in y over the change in x. That just tells me a typical slope.

[Response to 3] Again, I probably am finding a slope, an average slope, so I need a change in something over a change in something else. Probably a combination of z, x and y? Again, it would just tell me a typical slope.

Jane:[Response to 1] Well, it would be the most common mass of all of them, kind of giving me information about the seventh lure.

[Response to 2] The average rate of change tells me the most commonly occurring rate of change of all the rates of change, infinite of them in the interval. I find the change in y over change in x, and it tells me that, the most common value.

[Response to 3] Sure, I'm still finding an average rate, so I need something to divide into something else, probably change in z over a change in a combo of x and y. Gets me to the same point, the most commonly occurring rate of change. Like summing up all of the rates of change, and dividing by how many there are in the interval.

Discussion

Students' Concept Images

A concept image includes the properties of the concept, any mental pictures a student has ever associated with the concept, and a concept definition. Vinner (1983) writes that a concept

definition is “a description of our concept image [and is] either taught to us or made up by us when we are asked to explain the concepts to somebody” (p.294). By ‘made up,’ Vinner means that students construct definitions as a result of their experiences with the concept.

We asked students to define ‘average’ and ‘average rate of change’ and the compare the meaning of the two, in addition to the questions in Figure 3. Many students expressed difficulty defining average (“everyone knows what average means”), and as a result we think their attempted definitions make good snapshots of their concept images. The majority of students’ concept images contained properties from everyday language and mathematics. For example, Jordan talked about an average mass as a typical mass and an average rate of change as a typical rate of change.

Mathematically, average may refer to mean, median, or mode (Triola, 2006) and students’ explanations reflected this ambiguity. Jane’s use of ‘most common’ and Jordan’s use of ‘what it is mostly’ are reflective of mode-as-average. Other students (excerpts not included) talked about average as a middle value or a balance point, reflecting average-as-median. While students described median and mode in their concept images for average, all students’ calculations for average mass were arithmetic means.

Students’ concept images for average rate of change reflected their concept images for average as a most common, typical, middle, or smoothed out value. For instance, Jordan talked about average as a most common value and talked about average rate of change as “the most commonly occurring rate of change of all the rates of change, infinite of them in the interval.” Brian talked about average as a smoothed-out value and described average rate of change as “You take the change in y over the change in x, that kind of smooths it out to determine it for you. I find the change in y over change in x, and it tells me that, the most common value.” While students frequently referred to computing average rate of change as taking the change in one variable divided by the change in another (e.g., Brian, Jordan, and Jane’s responses to 3), this seemed to be a rote procedure. That is, students did not seem to have an image of x,y and z as quantities or an image of a quantity changing with respect to another quantity at a constant rate.

We also identified a disconnect between the way students thought about average rate of change and their procedures: that is, they tended to think about it as a ‘smoothing out,’ a median, or a mode, but the procedure of change in one variable over change in another is more reflective of average-as-mean. We concluded that students were unsure when the different meanings for average were appropriate for a situation.

Ways of Thinking and Understanding

Harel and Koichu (2010) differentiate *way of understanding* as an in-the-moment process a student uses to construct meaning and *way of thinking* as a characteristic way of understanding. We looked at students’ ways of understanding average and average rate of change in computational problems, then looked for similarities in ways of understanding that would constitute ways of thinking. We found that students’ ways of thinking about average rate of change mirror their ways of thinking about average.

Students’ ways of understanding average included properties like normal, typical, mediocre, common, arithmetic mean, median, middle, center, balance point, mode, most common number, smoothed-out value, representative value and expected value (Figure 1). Their ways of understanding average rate of change included arithmetic mean, expected value, most common rate of change, typical rate of change, rate of change representative of all rates of change, and a smoothed-out rate of change (Figure 2). The overlap in ways of understanding across context

indicate that students bring their way of understanding average to their way of understanding average rate of change. Moreover, these ways of understanding constitute ways of thinking for many students. We base this conclusion on the observation of patterns in students' ways of understanding across three compute-the-mean problems and four conceptual average rate of change problems.

We conclude that students' ways of thinking included a number of elements from ways of understanding an idea in different contexts. In the case of average rate of change, these ways of thinking seem to prevent students from thinking about average rate of change as a quantity changing at a constant rate with respect to another quantity.

Implications

Instantaneous Rate and Extensions

Our characterization of students' concept images for average and average rate of change has implications for how students think about instantaneous rate of change and for how they extend their way of thinking about rates of change to three dimensions. Many of the students who thought about average as an arithmetic mean determined that average rate of change was an arithmetic mean of a finite number of instantaneous rates of change. They could hold this conception in mind because they thought about an instantaneous rate as slope (a picture) without a measuring process attached to it. Thus, for these students an instantaneous rate was similar to the weight of a lure, and the average rate of change was an arithmetic average. This way of thinking ignores the limiting process in measuring a rate of change, and does not focus on measurement of quantities to determine how fast one is changing with respect to another. When the students attempted to determine how to interpret and measure rate of change in space, they relied on their image of instantaneous rate as a degree of slant of a line (without problematizing direction), and the average rate of change as an arithmetic mean of the degrees of slant. This way of thinking allowed the students to ignore the issue of direction in space and the limiting process that makes possible the computation of a derivative. These ways of thinking support a non-quantitative conception of rate of change for two reasons. First, the measurement of quantities is unimportant. Second, and partially because of the first, the limiting process is not necessary for the student. These issues confound the understandings we intend that students have, and likely constrain students from seeing rate as a quantification of how fast quantities are changing.

Recommendations for Instruction

We propose that students must understand that average rate of change is a comparison of *change* in *quantities,* and that statistical average is a quantity that characterizes a number of quantities. We propose that the distinction between the uses of average can be supported using quantitative and covariational reasoning. (Thompson, 1994, 2011) In both statistic and calculus, students' understanding of average relies on quantities and their measures and students often associate the two because each uses division. However, average rate of change requires that students measure changes in quantities (quantitative reasoning), and compare those quantities to determine how fast one is changing with respect to another (a constant rate, requiring covariational reasoning). We believe that students must understand that while average rate of change and average in statistics use similar calculations, the result of those calculations represents different quantities. While space permits us from detailing a quantitative and covariational approach to teaching rate of change here, we have ideas for particular learning trajectory-type tasks that teach rate of change from these two perspectives.

Future Directions

Our results suggest that students use their concept images for average to make sense of average rate of change. These concept images often lack the element that rate of change is a measurement of the change in one quantity with respect to the change in another quantity. This leaves students to impart different meanings to [f(b)-f(a)]/(b-a) and these meanings are based on their meanings for the word average. In other words, they apply concept images that are not appropriate for the situation. Moreover, not thinking about a rate of change as quantities changing results in students not seeing a need to make the change in one of those quantities approach zero: that is, there is no need in students' minds for a limiting process. We believe that students' development of the meanings instructors intend requires not just taking into account, but rather using productively, their concept images for topics related to new material. Having documented these concept images, the next step is to determine how instructors can use these to their productively in teaching calculus.

We hypothesize that a focus on quantitative and covariational reasoning may help students develop the intended meanings for average rate of change, the limiting process, and instantaneous rate of change. While the importance of quantitative and covariational reasoning has been highlighted in algebra and differential calculus, limited work has studied the role of these ways of thinking in multivariable calculus. Our work suggests that these ways of thinking are critical for upper-level calculus, and future work is needed to determine how to best foster these ways of thinking.

This study explores the communicative accommodation strategies employed by a bilingual tutor and an ELL student during the discussion of word problems involving secondary algebra and geometry concepts. Mathematics discussions are conceived as communicative events wherein ELL student comprehension is promoted through provision of simplified linguistic input. The reported findings reveal that ELL student accommodation entails multiple dimensions, taking multiple (non)verbal forms with varied degrees of orientation toward language versus ideas and relative focus on literalness versus metaphoricity.

Keywords: Equity and Diversity, Classroom Discourse, High School Education

There is growing interest among mathematics educators in helping English Language Learners (ELLs) overcome the complex linguistic demands of mathematics instruction and promote their participation in mathematical discussions as legitimate members of the classroom community. To help mathematics teachers attain this goal, educational researchers have identified a variety of strategies. Mostly anecdotal in nature, this literature falls short of providing mathematics educators with more sophisticated, theory-based understandings of how to effectively accommodate the communicative needs of ELL students. Teachers in the lower-grade levels have also incorporated a variety of means to communicate mathematics and science content to ELL students. Commonly found in practitioner journals, this literature identifies a wide variety of communicative strategies that elementary and middle-school teachers can adopt in their own classrooms. Few strategies are identified specifically for teacher adoption at the high-school level.

In the present inquiry, we set out to attend to the above limitations in the mathematics education literature by using accommodation theory, drawn from the field of communication, to explore communicative strategies employed by bilingual speakers to construct meaning during the discussion of word problems involving secondary algebra and geometry concepts. More specifically, we tackle the following research question: What accommodation strategies do a bilingual tutor and an ELL student adopt to overcome comprehension problems and communicate effectively during discussion of mathematics word problems? In the following section, we discuss our theoretical perspective.

Accommodation Theory

Drawing on theoretical and empirical work from the field of communication, we conceive of mathematics as a school subject whose communication requires mastery over a specific *register*, that is, a specialized subset or context-specific variety of language (Saville-Troike, 2003). Furthermore, mathematics word-problem discussions are viewed as dyadic communicative events, wherein a bilingual tutor (treated as a "native speaker" of the language of mathematics) facilitates the interpretation of complex written input by an ELL who is also a "non-native mathematics speaker" with limited proficiency in the mathematical register. To make communication possible and

overcome potential comprehension challenges, the tutor supports the novice learner by contextualizing input, making it more easily understandable or interpretable (Gibbons, 2003). Expert communicators interpersonally adapt (Burgoon, Stern, & Dillman, 1995) to their recipients' communicative abilities, leading toward a more accessible learning experience for ELL's (both in message understanding and reciprocation) (Hatch, 1983).

Scholarly efforts to analytically account for speakers' tendency to make speech adjustments such as accentual modifications in interpersonal encounters have been heavily influenced by *speech accommodation theory* which, according to Street & Giles (1982), posits that "people will attempt to converge linguistically toward the speech patterns believed to be characteristic of their recipients when they… desire a high level of communicational efficiency" (p. 213). When successful, such accommodation and mutually influential behavior results in the reduction or elimination of language barriers as well as proclivity toward *communicative convergence* or similarity in speakers' ways of talking (Ireland et al., 2011), typically being well received (i.e., positively evaluated) by listeners.

In the present study, we conceive of mathematics discussions as communicative events wherein a mathematics tutor strategically incorporates verbal and nonverbal accommodation. As Allen (2000) points out, "teachers who use the FL [Foreign Language] as the language of instruction typically make both verbal and nonverbal accommodations to facilitate learners' comprehension of the language" (p. 155). By combining accommodation talk and gestures, the tutor draws on the student's current understandings and experiences as resources (Moschkovich, 2002) for comprehension of the textual contents of mathematics word problems.

A variety of strategies have been identified to promote ELL students' mathematical literacy, knowledge, application, and skills. This literature points to multimodal instruction (the combined use of multiple modes of communication) as an effective means to accommodate ELL students. However, how such multimodality can be systematically designed and implemented by mathematics teachers is not completely clear. Further research is necessary in the area of multimodal mathematics instruction to clarify exactly how it can benefit ELL students and foster mathematics learning. As argued by Chval & Chavez (2012), teachers' use of multimodal strategies must be "purposeful… [and] target the development of language and mathematics for the ELLs in their classroom" which is not a task to be taken lightly; it is a task that "requires thoughtful conversations and planning" (p. 265).

Methodology

In order to explore the potential of multimodal dynamics in support of ELL mathematics learning, we conducted a microethnographic case study of tutor-student interactions. This particular inquiry adopted a qualitative research approach, a phenomenological underpinning, and aligned with socio-constructivist perspectives on human interaction (Robson, 2002). Patton (1990) states that case studies are used when "one needs to understand some special people, particular problems, or unique situation in great depth…" (p. 54). Our phenomenological orientation reflects our concern with participants' first-hand experience of a communicative phenomenon, namely accommodation. This case was explored through descriptive data systematically collected through open-ended research methods (video-recorded observations) and analyzed inductively to build a naturalistic account of a bilingual tutor's accommodation strategies when discussing mathematics word problems with an ELL student.

Our dataset was composed of ten hours of video-recordings of bilingual exchanges (Portuguese/English) between one of the authors (Alan Oliveira) and a female ELL student (Cassie) during one-on-one mathematics tutoring sessions. The curricular material was written exclusively in English, while the discussions were bilingual with Portuguese as the dominant language, the predominantly used linguistic code (Saville-Troike, 2003) in the oral mode of communication. As such, our video-recordings offer a unique opportunity to examine discourse strategies deployed by a

bilingual tutor to accommodate an ELL student's communicative needs and hence enable her to participate, by drawing on her bilingual capabilities, in mathematical word problem discussions involving secondary algebra and geometry concepts.

To examine accommodation strategies adopted by the mathematics tutor and ELL student to promote comprehension, we first transcribed the video-recordings of the tutoring sessions and then conducted a *microethnography,* a study of language-mediated social interaction in minute detail through an up-close and exhaustive examination of how people use language and other forms of communication to realize the social work of their daily lives (Erickson, 1996). Gee and Green (1998) define it as "a research language that describes the ways members of a social group construct the structures of daily life" (p. 132).

Our microethnographic analysis was conducted at the level of *episodes* or *key cultural scenes* (Erickson, 1996); short stretches of naturally occurring discursive interactions (tutor-student dialogues) with variable number of utterances. This microethnographic analysis initially revealed a recurrent, three-stage pattern in the bilingual problem-solving approach: aloud translation, mathematical transcription, and mathematical calculation. More specifically, the tutor and ELL student first translated each word problem aloud from English to Portuguese, then transcribed the word problem into an equation or diagram (drawn on a large whiteboard in front of the classroom), and lastly made their mathematical calculations both orally and in writing. Based on this initial finding, a written report was then produced describing and illustrating the tutor's main accommodation strategies in each of the three different stages of their bilingual problem-solving approach.

Multiple strategies were adopted during data collection and analysis to ensure validity and reliability. First, our approach to data collection was aligned with a tradition of educational research known as *action research* (Lewin, 1946). As the mathematics tutor facilitating the discussion, Alan was actively involved with the phenomenon being researched. This ensured familiarity and an insider perspective on the bilingual context of instruction. Second, *peer debriefing sessions* with external researchers (not directly involved with the tutoring sessions) were frequently held during data analysis, wherein key scenes were examined collectively, individual analyses shared, and interpretations discussed extensively. The emergent account was gradually adjusted to include any variation that surfaced from this reflective group interpretation. These sessions were frequently held to triangulate emerging interpretations of the data and guard against individual researcher biases (Robson, 2002).

Findings

We now describe and illustrate general patterns which occurred during the bilingual problem-solving. Attention is given sequentially to accommodation strategies adopted during three different phases: aloud translation, mathematical transcription, and mathematical calculation.

Aloud Translation

Accommodation in this initial phase of the bilingual problem-solving process took various forms, verbal and nonverbal. Its main aim was to fill gaps in the ELL student's vocabulary that became evident when she was unable to orally translate a particular word problem from the source language (English) to the target language (Portuguese). The two main accommodation strategies deployed to ensure student comprehension of the written content of linguistically complex word problems were *literal translation* (i.e., explicit word-for-word translation of unknown terms) and *borrowing* (taking words from a source language when no equivalent exists in a target) (Fawcett, 2003). One instance of borrowing occurred when Cassie encountered difficulties translating the words "nickels" and "dimes," two words for which there are no one-to-one equivalent translations in Portuguese which compromised her ability to demonstrate her knowledge of mathematical meaning.

Upon noticing Cassie's inability to demonstrate her knowledge of the mathematical meanings associated with the two English words "nickels" and "dimes," Alan interjected by posing a *confirmation check* (Long & Sato, 1983), a type of question whose main function is to check whether students have understood previous discourse. His query "You do know that each coin in the United States has a name, right?" is multifunctionally designed, in the sense that, it serves not only as a request for the student to explicitly confirm her comprehension, but also as a source of critical cultural knowledge for the student to comprehend the book writer's intended meanings (i.e., it is both a prompt and a hint). This cultural hint is then elaborated upon by Alan who proceeds to disclose the mathematical meanings behind each term used for informal refence to particular coins in English. Despite the unavailability of equivalent terms for "nickels" and "dimes" in Portugese, Cassie is then able to successfully perform her aloud translation of the problem through borrowing.

Nonverbal accommodation during aloud translation took the form of *deictic gestures* (McNeill, 1992). More specifically, Alan used his index finger to point to objects nearby and designate the contextual location of the referent of unknown words or expressions. This particular accommodation strategy was deployed when Cassie experienced difficulty translating the expression "minute and hour hands of a clock;" he reacted by pointing with his index finger to the clock in the back of the room. Cassie's difficulty stems from the fact that Portuguese speakers use the word "ponteiros" which literally translates into English as "pointers." However, rather than simply providing Cassie with a direct tranlation of the non-literal meaning of the word "hands," Alan encourages her to independently deduce its meaning from direct examination of a real clock in the immediate classroom context. His pointing serves as an *illustrator*, that is, a type of gesture designed to physically illustrate the meaning of accompaning speech (Burgoon, Buller, & Woodall, 1989). By witholding and delaying his provision of a direct translation ("A pointer is what he is talking about"), Alan encourages Cassie to actively and independently translate words based on the available information, context, and her own experience rather than being passively told its meaning in the target language.

Mathematical Transcription

Verbal accommodation in this second problem-solving stage took the form of *simplified rewording*. Because issues with translation had already been handled at this point, verbal accommodation typically took the form of restatement within the target language, as opposed to word transposition across languages. A good example of this form of accommodation took place during mathematical transcription of a problem which involved comparing line segments in a given ratio on the same line. Although Cassie had already been able to translate the word "respectively" into its Portuguese equivalent "respectivamente" without any problems, she had difficulties demonstrating that she had a clear understanding of the meaning of this term during mathematical transcription of the word problem into a geometrical diagram. This was evident during an exchange in which Cassie described how the diagram should be drawn.

By succesfully translating the word problem aloud,Cassie initially gives the impression that student comprehension has occurred and teacher accommodation is not needed. However, when Alan probes further by prompting Cassie to describe how to mathematically transcribe the word problem, it becomes apparent that she does not comprehend the meaning of the word "respectively" as used in the mathematical register. This lack of comprehension becomes particularly evident when Cassie fails to succesfully answer Alan's query "so, M and N respectively, so M is whose midpoint?" By re-articulating the word problem in everyday Portuguese terms, Alan provided Cassie with simplified input, thus accommodating the student's communicative needs not only in English but also in the mathematical register in her own native language.

Nonverbal accommodation during mathematical transcription took the form of *iconic gesticulation* (McNeill, 1992), that is, hand gestures that shared some sort of spatiotemporal correspondence (e.g., trajectory, direction) with abstract ideas or processes being representationally

communicated. This visual form of accommodation was deployed by Alan when he sought to help Cassie comprehend why the mathematical statement “the length of each side of a square (represented by the letter L) is 3 more than the length of each side of a regular pentagon (represented by the letter P)” was correctly transcribed as “L = P +3.”

Alan uses his arms and hands to iconically express mathematical equality in terms of vertical spatial relations (up/down). Through his arm movements equality is spatialized as a state wherein both his hands (each representing one side of a mathematical equation) are at equal heights. Achieving this state requires either lowering the higher hand (i.e., subtracting three units from one side of the square) or raising the lower hand (i.e., adding three units to one side of the pentagon). Alan’s iconic gesturing provides an image of mathematical equality, a conception with which Cassie seems to be struggling.

Mathematical Calculation

Verbal accommodation in this final phase also included deployment of simplified rewording within the target language. For example, while calculating the angles in a geometrical diagram Alan noticed that Cassie attempted to do her mathematical calculations through visual inspection despite the note “figure not drawn to scale.” Despite being able to translate the mathematical expression “not drawn to scale” aloud, Cassie’s subsequent actions (in this case mathematical calculation) reveals that she has not in fact comprehended the message, leading Alan to restate the mathematical register in simpler layterms she can more easily comprehend: “it’s just a little scheme, it’s not measured” and “it’s not measured, they did not measure it carefully.” A very similar instance was observed in a different problem with the mathematical word “adjacent,” which was first translated aloud by Cassie as “adjacente” (its Portuguese cognate) and later simplied by Alan (also in Portuguese) as “near, side-by-side” and “right by one’s side.” In both instances, student comprehension entailed literal translation as well as simplified rewording whithin the target language. Put differently, literal translation did not always suffice as a means to accommodate the ELL student’s communicative needs, especially when dealing with academic or mathematical words. Because this lexicon is not commonly found in everyday parlance, ELL students may occasionally hear it and yet not fully understand its specialized meaning within the mathematical register.

During mathematical calculation, there was also noticeable instances of combined verbal and nonverbal accommodation, usually in the form of *conceptual asides* – brief interruptions in the normal course of mathematical calculation to fill gaps in the student conceptual knowledge. One particularly interesting conceptual aside took place during discussion of a problem where the length of two of the sides of a triangle was provided. Upon noticing that Cassie lacked familiarity with the triangle inequality theorem, Alan interrupted the mathematical calculation to provide a conceptual aside. Rather than simply telling Cassie what this mathematical theorem formally states (i.e., that the sum of the lengths of two sides of a triangle must always be greater than the length of its third side) or the correct inequality for the given triangle, Alan engaged Cassie in a short discussion about a generic triangle drawn separately from their ongoing mathematical calculations. Not only is the triangle inequality theorem communicated in simple lay terms, but it is also made visually accessible through metaphorical spatialization, thus accommodating Cassie’s communicative needs and ensuring her comprehension.

Discussion

The reported findings reveal that teacher accommodation of ELL students entails multiple dimensions. In addition to taking varied (non)verbal forms (the previously known dimension Verbal–Visual), accommodation can also be analytically placed along two additional continua (Linguistic–Epistemic and Literal–Metaphorical), depending upon their degree of orientation toward language versus ideas and the relative focus on literalness versus metaphoricity, respectively. These two additional dimensions are discussed below.

Linguistic and Epistemic Orientation

Our findings revealed that tutor accommodation during bilingual problem solving had varied degrees of linguistic and epistemic (conceptual) orientation. These varied degrees were evident in the fact that the tutor's accommodation strategies were sometimes more focused on promoting ELL student comprehension of linguistic meanings (the textual contents of word problems) than on mathematical meanings (mathematical concepts or ideas ecompassed in the word problem or required for its resolution). At other moments, the primary focus was on mathematical meanings while linguistic meanings remained secondary. Linguistically-oriented accommodation was characterized by an English-Portuguese focal alignment, wherein the tutor took on the role of a foreign language educator who helped the ELL student comprehend a word problem by explicitly establishing semantic equivalence (House, 1997), that is, identifying equivalent words in the target language. This type of accommodation invariably entailed *code switching* (Saville-Troike, 2003), strategic interlinguistic changes from English to Portuguese, typically taking the form of "label quests" (Martin, 1999).

By contrast, epistemically-oriented accommodation strategies had a Portuguese-Mathematics focal alignment, typically entailing *register switching*, intralinguistic changes from an academic to a conversational register (Cummins, 2000) within the same language (Portuguese). By strategically rewording academic and nonliteral mathematical words, the tutor assumed the role of a mathematics teacher who sought to help a mathematics learner comprehend specialized mathematical meanings needed for accurate mathematical transcription and calculation. Accommodation strategies with such epistemic orientation were aimed at enhancing the ELL student's conceptual knowledge (as opposed to improving her English proficiency). It is clear from this literature and our findings that effective ELL accomodation needs to be more focused on language meaning than language form, and that attention to conceptual understanding, in either the ELL student's first or second language, is necessary for academic achievement.

Literal and Metaphorical Accommodation

Previous educational efforts aimed at accommodating ELL's communicative needs have been limited to student comprehension of literal input, for the most part overlooking the need for more metaphorical forms of accommodation. This tendency to focus accommodation of ELL students on the concrete is particularly evident in mathematics educators' frequent use of manipulatives (Fernandes, 2012), science educators' deployment of pictorial and replica models (Buck, Mast, Ehlers, & Franklin, 2005), and language educators' use of realia (real artifacts or cultural objects) (Ash, Tellez & Crain, 2009). However, as it pertains to mathematics instruction, such a trend is problematic in the sense that it is inconsistent with current scholarly work in the field of cognitive science which has highlighted the centrality of metaphoricity to mathematical thought and revealed the underlying metaphorical structure of basic mathematical ideas. The present shows how metaphorical accommodation in mathematics instruction can be effectively accomplished through strategic deployment of iconic gesticulation. More specifically, we found that iconic gestures served an important accommodation function during mathematical transcription and calculation, metaphorically structuring abstract mathematical concepts of algebraic equality and representing the triangle inequality thereom in nonliteral space. Such a finding is consistent with existing research showing that professional mathematicians use iconic gesturing to make metaphorical mathematical meanings more accesssible and comprehensible to others (McNeill 1992) and that non-native language learners can effectively employ gesticulation to overcome communicative difficulties by compensating and eliciting help in the course of multilingual exchanges (Gullberg, 2011).

Significance and Future Research

The main significance of the present study is that it introduces a theoretical framework for systematically examining ELL student's comprehension in mathematical discussion. The present

study increases the linguistic diversity of this research base by focusing on Portuguese. Our findings also have practical significance for classroom instructors of mathematics. In essence, the reported tutoring practices underscore how effective accommodation for ELL students during mathematical discussion requires continuous assessment of student comprehension. Such finding is consistent with the available literature which clearly shows that tutors, teachers, and peers successful in assisting ELLs are consistently attentive, noticing and adjusting to (mis)understanding as they go (Gerena, 2012). Rather than recurrently resorting to a single communicative strategy, the tutor deployed a variety of techniques as he continuosly assessed and adapted to the ELL student's ability to comprehend the contents of mathematical discussion.

The reported findings point to potentially productive direction for future research. Evidence exists that many mathematics teachers lack awareness of the central role of language in mathematics learning as well as the importance of making linguistic accommodation for ELL students (Fernandes, 2012). In a similar vein, Echevarria, Vogt and Short (2008) point out that few content teachers receive in-service training on how to effectively teach ELLs and very few pre-service teacher education programs include instruction on teaching this rapidly growing student population. Such a state of affairs suggests a need for teacher educators to facilitate professional development that can make mathematics teachers more aware of the multiple dimensions of linguistic accommodation and use these dimensions as guiding principles for systematically designing and implementing mathematics instruction that can effectively promote ELL student comprehension of mathematical principles and concepts in their classrooms.

The present study takes a first step in this direction by identifying several strategies that mathematics teachers can potentially combine for the purpose of accommodating students in larger classroom settings. Nonetheless, despite this valuable initial insight, further analytical consideration will need to be given to how the identified strategies can be effectively integrated by teachers to promote multilingual accommodation in regular mathematics classrooms.

CONSTRUCTING IDENTIFICATIONS WITH MATHEMATICS PEDAGOGIES, DIS/ABILITIES AND "OUR DOMINICAN SELVES"

Rachel Lambert
Loyola Marymount University
mathematizing4all@gmail.com

How do children develop identifications with mathematics over time, seeing themselves as agents in their math classrooms (or not)? This ethnographic and interview study followed nine Latino/a children with and without learning dis/abilities through two years of mathematics in a high-poverty urban school. The children participated in two distinct mathematical pedagogies (discussion-based and procedural-based) that differently constructed ability and dis/ability in mathematics. Individual children constructed unique and dynamic self-understandings as math learners over time, using the cultural resources of the multiple contexts in which they participated, including positioning through language use, ethnicity, gender, and dis/ability. Children made connections between equity and discussion-based mathematics, and between procedural mathematics and fixed conceptions of mathematical ability.

Keywords: Equity and Diversity, Curriculum, Affect, Emotion, Beliefs, and Attitudes, Gender

Purpose of the Study

As a classroom teacher and a teacher educator, I have met many children and adults who readily identify themselves as particular kinds of math learners, such as "I'm just bad at math" or "I'm not a math person." My work asks how such self-understandings around mathematics develop. How do they change? How do these self-understandings matter for learning over time? I am particularly concerned about these questions for children who have historically had less access to high level mathematics: Black and Latino children, children from low-income families, girls, and those with disabilities. This study is situated within a high-poverty urban school with Latino/a children in order to better understand the ways in which social positioning intersect with mathematics, understanding that Latino/as continue to be overrepresented in special education particularly in the categories of learning disabilities and behavioral disorders (Losen & Orfield, 2002; Artiles et al., 2010).

Theoretical Frameworks

This study assumes that self-understandings are created through participation in social worlds. Within "figured worlds" (Holland et al., 1998), participants create and recreate particular cultural practices and discourses (Nasir & Hand, 2006), with particular habits of making sense both of others and oneself. A single mathematics classroom has multiple figured worlds intersecting within it (Esmonde & Langer-Osuna, 2011), providing multiple sets of resources for understanding oneself as a math learner. This study focuses on processes of identification, providing analysis of the process through which children appropriated various discourses and practices around mathematics (Holland et al., 1998; Bakhtin; 1981).

All figured worlds position participants, particularly in terms of gender, race, class, ethnicity and dis/ability. While all of the children in this study were officially listed as Hispanic, they described themselves in terms that moved beyond limited categories: "I speak Spanish but also English"(Ana, Second Interview) and "I am from the Dominican Republic but I was born here"

(Ruby, Second Interview). Following feminist scholars such as Gloria Anzaldúa (1987), the purpose of my work is to understand people as complex and dynamic rather than static. I also approach disability with the same attention to complexity rather than categorization. Disability studies in education (DSE) recognizes that although individuals may have natural biological variation in how they learn (*neurodiversity)*, it is the social effects of difference that disable (Gabel, 2002; Reid & Valle, 2004). Disabilities depend on context for their form and meaning: an individual may be seen as learning-disabled in one mathematics classroom and not in others (McDermott et al., 2006).

Methodology and Data

As a white, non-disabled, middle class woman researching the experience of Latino/a children from low-income homes, I understand social positioning as not only a theoretical, but also a methodological issue. In order to understand the multiple figured worlds interacting in the classroom as an outsider, I needed a methodology that was sensitive to the complexity of experience. I also knew that I needed multiple interviews with children in order to understand processes of identification with mathematics over time.

Research Questions

1. In one middle school mathematics classroom, how do cultural practices construct and display particular kinds of mathematical ability and disability?
2. How do children, both labeled as learning disabled and not, construct and enact understandings of themselves as math learners?

Participants

Located in a large city, Central Academy Middle School predominantly enrolled Latinos (92%) with a poverty rate of 85%. Although this was a two-year study, this paper will focus on the seventh grade mathematics class. This inclusion class included 24 total students, 12 of which had an Individual Education Plan for learning disabilities. Students with IEPs in special education were placed into a single classroom at each grade level with two teachers, in this case a math and a special educator. Ms. Marquez, the math teacher, was Latina. She had nine years of experience teaching math at the secondary level. Ms. Alton, the special educator who joined the class halfway through, was African American. She was in her first year of teaching. Out of nine focus children, six were girls and three were boys. Six out of nine had IEPs while three did not. Two children with IEPs were also classified as English language learners. All of the children were identified as Latino/a.

Data Collection and Analysis

I made twenty-six visits to the ninety-minute seventh grade mathematics class. For each visit I wrote field notes and twelve classes were also video-recorded and transcribed. Using grounded theory (Glaser, Strauss & Strutzel, 1968), I developed claims about the cultural practices and positioning of the math classroom, and then tested those claims concurrently. To understand the mathematical practices, I separated the ninety-minute class periods into different activities, coding each segment for type of mathematical pedagogy. I carefully tracked children's learning of integers over time, using data from participant observation, analysis of video recordings, student work and a final assessment of computation.

I interviewed the nine focus children twice in their seventh grade year. The first interview was semi-structured, in pairs to increase discussion. The final interview was individual. I analyzed these interviews through narrative analysis (Riessman, 2007).

Results

Ms. Marquez's classroom followed a fairly consistent schedule. Children came in, sat in assigned seats, and quietly began to solve a Warm Up math problem. Ms. Marquez would then lead a discussion based on the problem. Ms. Marquez would then split the children into three groups. On most days in the fall, children rotated between these groups, sometimes working independently and at other times with a teacher.

Early in the fall, Ms. Marquez asked me if I had noticed the "two different sides" of her math class, what she called "critical-thinkingish" and "state-examish"(field notes, 9/28/10). I had noticed that most of the ninety-minute classes began with 30-45 minutes of "critical thinkingish" math, or discussion-based math, before shifting to "state examish" or procedural math. Each way of doing mathematics had its own set of discourses, practices and positioning. I understood each as a separate figured world.

The figured world of discussion-based mathematics emphasized the practices of problem-solving and discussion, particularly sharing multiple strategies and asking questions. During discussion of Warm Up problems in the fall, Ms. Marquez typically asked for multiple strategies, listening to the children's answers and representing their thinking. When children disagreed, she facilitated discussion, using strategies such as revoicing (O'Connor & Michaels, 1996). In the fall, children also occasionally worked in groups on open-ended problem solving which also emphasized multiple strategies. Ms. Marquez spoke with a questioning voice during these activities, placing accountability in the hands of the students (Engle & Conant, 2002).

The work in the second half of the class tended to be procedural mathematics. Children were given packets of work sheets in order to practice a new procedure or review an old one. In the figured world of procedural mathematics, valued practices were being able to solve a range of computational problems independently and quickly, ideally using only memory. The discourses of procedural mathematics were concerned with efficiency and speed. During procedural mathematics, Ms. Marquez emphasized following already determined procedures, placing accountability in the teacher.

Ms. Marquez always began a mathematical topic using discussion-based practices and gradually transitioned to procedural work. Work on integers began with extended discussion of multiple strategies to solve integer addition and subtraction problems, often modeled on the number line. One week later, these discussions were replaced with memorization of set rules for addition and subtraction of integers. Once the rule was established, children tended to use the rule because it had the most status. By the middle of the year, children told me the number line was a "crutch" and "for beginners"(Federico, First Interview).

Some children used the figured world of discussion-based mathematics to understand themselves as math learners. One boy, Luis, explained the difference between discussion-based math and procedural math: "problems that give you problems" versus "worksheets which are nothing"(Luis, First Interview). Luis preferred discussion-based math, enjoying this kind of work so much that he would sometimes hide open-ended problems under his worksheets, working on them secretly. His narratives about mathematics emphasized his persistence in problem solving and his creative solutions. More commonly, children used the figured world of procedural mathematics to understand themselves as math learners. A girl named Ana told me in an interview that she was the kind of learner who had to "practice and practice" until she "got it"(Ana, First Interview). Many children emphasized two kinds of math learners, those who "get it right quick" and those who "struggle"(Arturo, First Interview).

In the fall, children engaged in both kinds of mathematical practices. Out of thirty-four different class activities documented in the fall, twenty were procedural and fourteen were

discussion-based. In the second half of the year, the balance shifted. From January until May, Ms. Marquez eliminated almost all discussion-based math, focusing instead on preparing for the test. Out of thirty coded activities from January to June, twenty-eight were procedural and two were discussion-based.

This shift in pedagogies caused some children to appear more disabled, and others less so. In the fall, Ms. Marquez saw Luis as an innovative problem-solver, while she questioned Ana's ability to understand conceptual work. Luis became a concern for Ms. Marquez in the spring because he was not able to memorize rules. Ana, who identified with procedural mathematics, had the opposite trajectory in the class. In the spring, Ana was on the honor roll, no longer a concern as she was able to memorize procedures called for on the state exam. During discussion-based activity, Luis was deeply engaged. When activity was procedural, Luis was frequently disengaged. During the spring, as the class was focused on preparing for the state exam, Luis's special education teacher, Ms. Alton, repeatedly referred to Luis as "a behavior"(field note, 3/23/11), alluding to a special education designation that Luis did not have. Both Luis and Ana had a label of learning disability. Their differences as learners remind us that there is no one mathematical profile of a child with a learning disability. Almost all the children had some kind of shift in status as the math pedagogy changed, except for a small set of children who seemed able to do both kinds of mathematics.

These two figured worlds of mathematics, that of discussion-based and procedural mathematics, were not the only figured worlds circulating in the classroom. There was also the figured world of schooling, comprised of practices such as lining up, sitting still, and talking in particular ways in the classroom. There was also the figured world of friendships, which was characterized by practices of care work, such as working together with a friend on a math problem. A girl named Esa told me about three kinds of kids in the classroom: "*chistosos*, serious people, and outsiders"(Esa, First Interview). *Chistosos* made jokes in the class, but also tended to engage enthusiastically in procedural mathematics. Serious people were those in the class who took both the practices of schooling and the practices of friendship seriously. Outsiders were those who placed less importance on social relationships. Like the groupings of the high school students that Paul Willis (1977) found in his study of working class youth in English high school, these groups were engaged not only in participating in the practices of the school, but in creatively reworking those practices. The *chistosos*, for example, used hip-hop to express their quickness at procedural mathematics, remixing the figured worlds of the classroom.

Outside of the creative remixing of the *chistosos*, mathematics was separated from language, culture and children' experiences. Luis incorporated issues of social identities into his mathematical understandings, telling me for example that he imagined zero on a number line as the border between Mexico and the United States when he was adding and subtracting integers. In interviews, children repeatedly discussed being taught mathematics at home and in the Dominican Republic in the summers. Such experiences were not part of their experience in math class. Although most children and Ms. Marquez were bilingual, math was discussed only in English. Children told me that they felt this separation. When I asked a girl named Desi if she ever spoke Spanish in mathematics class, she told me no, that Spanish was for when they were "our Dominican selves" and not for "being serious in some subject"(Desi, Second Interview). The figured world of friendship was the only one in the classroom that was bilingual.

The final figured world I found in this classroom was that of dis/ability. Throughout the fall, grouping within this class was heterogeneous. In January, I noticed a new adult in the class, a soft-spoken teacher named Ms. Alton. After class Ms. Marquez told me that the new groups were

tracked, designed to keep all the children with IEPs together so that they could receive services from Ms. Alton (field notes, 1/4/11). One group was all children with IEPs, another group included no children with IEPs, and another group was a combination. The teachers never explained to the class the reasons behind these groupings. Some children took up the discourses of schooling to explain the grouping, telling me that the highest group was “independent” because they are “most trusted” by Ms. Marquez (Clementine, First Interview). Other children took up discourses of disability that I also heard from Ms. Alton; some children “learn differently” and “need different methods”(Federico, Second Interview; Ms. Alton, Teacher Interview).

Most of the focus children took up the discourses of ability and disability in procedural mathematics to understand how the groups were formed. A boy named Arturo told me about two types of learners: those who “get it right quick” and those who “struggle”(First Interview). If you did not know immediately how to solve a problem, you struggled. If you struggle, you “barely understand”(Albert, First Interview). As procedural math dominated, children increasingly used this binary of *get it fast* versus *struggle slow* to understand themselves and others. Comparing the first set of interviews with the second set of interviews, these binaries were increasingly used to explain both oneself as a learner, and to classify, organize and sort others.

Not all the children constructed their understanding of themselves as math learners from the figured world of procedural math. Two of my focus children consistently used the discourses and practices of discussion-based math to understand themselves as math learners. In his first interview Luis did not believe that there was a difference between different learners in his math class, even though “if I am thinking about it in one way, and another person thinking about it in another way, he might be smarter than me at that, but no body is better than nobody else” (Luis, First Interview). Luis kept a similar narrative across the year, insisting on equity in the math classroom. Competence is open for each new problem, a very different conception of competence than the increasingly fixed ideas of most of the children. Luis’s words are an example of a script I heard from multiple kids: “many ways, none is better”(Carmen, Second Interview). This quote comes from a girl named Carmen, describing to me how gender operated in the classroom. Carmen understood herself using the figured world of procedural mathematics, telling me one day she was “smart” at math (5/25/10) and the next “I hate math because I suck at it”(field notes, 10/12/10), each time because of how comfortable she felt with the procedures being used. But Carmen moves out of this binary when she discusses gender and ability and mathematics, using the discourses of discussion-based mathematics. While most children used the binaries of get it fast or struggle slow to understand themselves and others as math learners, when they reflected on situations involved gender or racial equity, they used a different discourse about mathematical competence.

I looked not only at the way in which children constructed self-understandings, but how those self-understandings evolved over time. Over the course of the year, I saw that some children were identifying more with mathematics, while others were distancing themselves. For those who continued to predominately author themselves as agents in mathematics, some used discourses from the figured world of procedural math. Federico used discourses of disability to author himself as simultaneously fast and slow. Others also authored themselves as agents in mathematics using discourses from discussion-based math. Luis, for example, even though he was positioned as unsuccessful in the spring, still authored himself as an agent in math, citing his own persistence and creativity.

About half the focus kids did not author themselves as agents in mathematics. Two of the girls, Rita and Ana, told narratives of de-identification with mathematics, telling me repeatedly and in multiple ways—I used to like math, now I don't. Both of these girls were on the honor roll in the spring, but rejected what they described as the stressful process of memorizing rules. A final trajectory was not of de-identification, but of never identifying with mathematics. These children, also both girls, told stories of perpetual struggle and resistance around mathematics, particularly focused on troubling relationships with teachers and family members around mathematics. My focus children were fairly evenly distributed between these four trajectories. While these patterns emerged, all the children constructed unique and dynamic mathematical selves, built from materials of multiple figured worlds.

Discussion

Several strands of educational research have recently focused on the ways in which children conceptualize their own ability in school subjects. Complex Instruction, developed by Elizabeth Cohen (1999) explicitly addresses these self-understandings, asking teachers to stress multiple abilities. The work of Carol Dweck (2000; 2007) on mindsets focuses on the critical importance of these self-understandings, affecting achievement. Developing flexible understandings of one's ability that hinge on effort rather than innate ability is a critical goal of educators.

First, my work shows that pedagogy mattered for these kinds of self-understandings. Second, the connection between equity and competence demonstrated that the children had narratives of equity that they brought into their narratives when gender or race was in play. They also brought forward powerful narratives from disability studies in education about being "labeled"(Desi, Second Interview) by the way teachers perceive their disabilities. Yet that same child, Desi, would shift back into static conceptions of ability and disability when discussing mathematics. I heard narratives of equity from Desi in all areas of her educational life except for in mathematics, suggesting both that mathematics has a particularly long road ahead of us in order to change the way children think of themselves as math learners, but also that we can build on powerful narratives of equity outside of mathematics.

Finally, and perhaps most important I worked on describing the process through which self-understandings develop. The kinds of self-understandings that I saw as fixed when I began this study, such as "a math person," were certainly not fixed. Attending closely to self-understandings over time, I saw kids define themselves in different ways at different times, based on the complex context of the classroom and their lives. I learned that children engage in multiple practices in math class, are positioned within these practices, and position themselves. Through their engagement in intersecting figured worlds: procedural and discussion-based mathematics, friendship, schooling and disability, the children worked and reworked their relationships, identities and positioning. The authoring of mathematical selves was always in process, making sense of these multiplicities. But possibilities were narrowed when the curriculum narrowed, when more children used the binary of get it fast or struggle slow to understand themselves.

I found that these self-understandings mattered both in their engagement, and in the choices they make about their mathematics education. Children used self-understandings to orient themselves towards mathematics work every day. There was a dynamic, dialectical relationship between self-understandings and mathematical activity for all the children.

Mathematical ability and disability were differently defined within different pedagogies in these classrooms, causing young people with disabilities to be seen as more or less disabled as

teaching practices changed. The cultural practices of schooling and sorting children, here the intersection of high-stakes testing, special education and tracking, not only reflected, but constructed certain ideas of ability and disability. When I began this study, I expected to see ability and disability change based on pedagogies, but I thought it might be a subtle difference, not the pronounced pedagogical shift that I found. This shift, coming as it does from the conflict between mathematical reform pedagogies and current high stakes testing reforms, is not limited in scope to this classroom, but widespread. Neoliberal policies which value multiple-choice test scores above all else will continue to create classrooms in which children that cannot memorize procedures and facts are disabled.

THE GROUPS OF STUDENTS PROBLEM: INSIGHTS ABOUT MULTIPLICATION AND IMPLIED ORDER IN COMBINATORIAL ENUMERATION

Elise Lockwood
Oregon State University
Elise314@gmail.com

Counting problems have applications in probability and computer science, and they provide rich contexts for problem solving. Such problems are accessible to students, but subtleties can arise that make them surprisingly difficult to solve. In this paper, students' work on the Groups of Students problem is presented, and an important issue related to multiplication (a fundamental aspect of counting) is discussed. Examples from two categories of students are presented – those who were able to make sense of a correct solution to the counting problem, and those who were not. Evidence is provided that many students failed to attend to the implied order in the multiplicative process, and a productive way of thinking that emerged for some students is also shared. Pedagogical implications and suggested avenues for further work are provided.

Keywords: Post-secondary Education, Advanced Mathematical Thinking, Probability

Introduction and Motivation

As one aspect of discrete mathematics, combinatorial enumeration (the study of counting problems) has received attention in both K-12 and undergraduate curricula, emerging as an important facet of problem solving and probability (e.g., CCSS, 2010; English, 2005). While counting problems are often simple to state and explore, they contain sophisticated mathematical ideas. In spite of their accessibility, there is evidence that students are often unsuccessful when solving counting problems (e.g., Eizenberg & Zaslavsky, 2004; Hadar & Hadass, 1981; Author, Date). Given that discrete and combinatorial topics are something with which mathematics and computer science students should have facility, there is a need for mathematics education researchers to look harder at students' work on counting problems and to attend to potential ways in which students may succeed on such tasks. In this paper, results from student work on one particular *Groups of Students* counting problem are reported. Through the exploration of student work on this problem, the research goal addressed in this paper is to present and discuss students' difficulty in recognizing a key issue related to multiplication – that multiplication implies a process with ordered stages. Some students never resolved this issue, but those who did used outcomes as a means of making sense of the issue. By focusing on one counting problem, we can go into significant mathematical detail, pulling apart some especially salient mathematical issues that might arise more broadly for students. The goal is to use the case of this particular counting problem to identify issues that might be more generalizable for students as they solve other counting problems. This work suggests that students' conceptual understanding of multiplication in counting may be limited, and that students' correct and incorrect assumptions about multiplication should be examined in greater detail.

Literature Review and Theoretical Perspective

There is ample evidence in the research literature that students struggle with correctly solving counting problems. For instance, Hadar & Hadass (1981) identify pitfalls that students face in solving counting problems, and Eizenberg and Zaslavsky (2004) report low success rates for undergraduates. Authors of combinatorics textbooks also underscore the difficulty of counting problems, as Martin (2001) calls the first chapter of his college-level textbook "Counting is Hard," and Tucker (2002) stresses that his counting chapter "is the most important and difficult chapter" in

his textbook on applied combinatorics. Several mathematics education researchers have tried to identify reasons for such struggles, examining strategies that might be productive for students (e.g., English, 1991), studying the effects of implicit combinatorial models (Batanero, Navarro-Pelayo, & Godino, 1997), and investigating students' verification of counting problems (Eizenberg & Zaslavsky, 2004). Halani (2012) looked beyond student difficulties in an attempt to identify ways of thinking that students employ in solving counting problems, and Author (Date) suggested that focusing on student-generated connections might be a productive way to understand how students conceptualize counting problems. In spite of such research, on the whole there is still much to learn about students' thinking related to counting, specific causes for student difficulties, and ways in which such difficulties might be allayed. In this paper, one potential factor of confusion related to multiplication in counting is highlighted.

Theoretically, this work is framed within a focus on mathematical issues of multiplication and order, and within Author's (Date) notion of a set-oriented perspective. Multiplication is undeniably foundational in counting problems. Informally, the multiplication principle is the notion that the total outcomes of a counting process is the product of the outcomes of independent stages of that process, and many refer to this as the "fundamental counting principle" (e.g., English, 2005; Sengadir, 2009). Tillema (2007) has focused on middle school students' multiplicative reasoning in the context of counting tasks, and his work suggests that multiplicative reasoning on such tasks is far from trivial. Students at a variety of levels often view multiplication as a simple task, and they tend to gloss over the details of why multiplication works on counting problems. However, while multiplication is often straightforward, situations can arise in which students encounter subtleties about multiplication in counting problems. In addition, issues of order are perennial in counting problems, and the question of whether or not outcomes should be ordered can determine which counting processes or formulas are appropriate. Several researchers have identified order as being a key element of students' counting (Batanero, et al., 1997; Mellinger, 2004), and the determination of whether or not order "matters" in a counting problem is not an insignificant task. Additionally, Author (Date) has argued for the importance of sets of outcomes as related to order. Author advocated a perspective that counting involves enumerating sets of outcomes, and that counting activity can be considered in light of structuring those outcomes. The findings below, and particularly the work of students who were successful at understanding the correct solution, are situated within this set-oriented perspective.

As the results and discussions show, the work described herein highlights a subtle aspect of multiplication – that multiplication can imply ordered stages in a counting process. This work emphasizes that this implied order in multiplication is perhaps not something to which students naturally attend. This paper presents student work on a task for which failure to attend to this important property of implied order in multiplication leads to problematic issues. The case is made that this aspect of students' multiplicative reasoning may deserve more explicit pedagogical attention and should be investigated further.

Methods

Participants. Twenty-two post-secondary students participated in individual, videotaped, 60-90 minute-long interviews. The students were junior, senior, and graduate mathematics students who had experience with fundamental combinatorial ideas such as binomial coefficients. The structure of these interviews was first to give students five counting problems to solve on their own. Then, students subsequently returned to these problems, during which time they were presented with alternative answers to evaluate (often these alternatives were reasonable but incorrect answers, developed in pilot work.) Typically, this resulted in students comparing two answers, both of which could seem reasonable, but one of which contained an error. This facilitated situations in which students evaluated incorrect but seemingly reasonable answers.

Tasks. The students each solved five problems, but in this paper the *Groups of Students* problem is emphasized. For this problem, both a correct answer and an incorrect answer are provided. While many correct and incorrect answers could be presented, two answers are given that are most relevant to subsequent discussion.

The Groups of Students Problem. The Groups of Students problem states, “In how many ways can you split a class of 20 into 4 groups of 5?” A correct answer to this problem is $\left[\binom{20}{4}\cdot\binom{15}{5}\cdot\binom{10}{5}\cdot\binom{5}{5}\right]/4!$. To arrive at this solution, five students are first chosen to be in a group, and there are $\binom{20}{5}$ ways to do this. Then, for each choice of the first five, five of the remaining students are chosen to be in another group, and there are $\binom{15}{5}$ ways to do this. Similarly, five more are chosen to be in a group, $\binom{10}{5}$, and then finally the last five to be in a group, $\binom{5}{5}$. These four terms are multiplied together because for each group chosen in a respective stage, there are a certain number of options available at each subsequent stage. However, it is noteworthy that this multiplication process assumes a first, second, third, and fourth group – the groups were developed in a particular order. Because of this, the product must divided by 4 factorial since the groups are not meant to be labeled or distinguished in any way. A typical incorrect answer is $\binom{20}{4}\cdot\binom{15}{5}\cdot\binom{10}{5}\cdot\binom{5}{5}$, which neglects the division by 4 factorial. Reasoning behind each of these answers are further detailed in the results section.

Data analysis. Initial data analysis involved transcription of the interviews. Then, the Groups of Students problem was targeted, and the author carefully analyzed and categorized students’ solutions to this problem. In an initial pass different solutions and strategies were characterized, and the implied order in multiplication was identified as mathematical theme of interest. Videos excerpt that related to multiplication were re-examined, and a narrative (Auerbach & Silverstein, 2003) about the students’ performances on the Groups of Students problem was constructed.

Results

The results are organized into two sections. First, overall numerical results are given, emphasizing that there was a low success rate on the problem. Second, to highlight particular mathematical issues that arose, work from two different students is presented, one who was ultimately *unable* to understand the correct answer, and one who was *able* to understand it.

Overall results. On the whole, students struggled with the Groups of Students problem. Only three of 22 students answered the question correctly on their first attempt (Table 1 provides a breakdown of students’ initial answers). Discussions during the interviews confirmed that the students had interpreted the problem as intended (as involving splitting the groups into four indistinguishable (not distinguishable) groups of five students).

Table 1: Frequencies of Initial Answers

Expression	Initial Answer	Correct/Incorrect	Frequency (%)
Expression (1)	$\left[\binom{20}{4}\cdot\binom{15}{5}\cdot\binom{10}{5}\cdot\binom{5}{5}\right]/4!$	Correct	2 (9%)

Expression (2)	$\frac{20!}{5!\cdot 5!\cdot 5!\cdot 5!\cdot 4!}$	Correct	1 (5%)
Expression (3)	$\binom{20}{5}\cdot\binom{15}{5}\cdot\binom{10}{5}\cdot\binom{5}{5}$	Incorrect	8 (36%)
Expression (4)	$\binom{20}{5}\cdot\binom{15}{5}\cdot\binom{10}{5}$	Incorrect	3 (14%)
Expression (5)	$\binom{20}{5}+\binom{15}{5}+\binom{10}{5}+\binom{5}{5}$	Incorrect	2 (9%)
	Other	Incorrect	6 (27%)

Student data. In this subsection, work of one representative student is presented from each of two categories of students (see Table 2; student work from categories in bold are presented in detail). First, work is presented of one of seven students who initially answered the problem incorrectly and was *unable* to make sense of why division by 4 factorial was necessary. The student's inability to recognize the implicit order in multiplication is emphasized, and reasons for this phenomenon are suggested. Second, work is presented of one of nine students who initially answered the problem incorrectly but was *able* to make sense of division by 4 factorial. The student's utilization of a specific outcome allowed him to recognize the need for the division by 4 factorial. The two students' work is contrasted. In the Discussion section, major themes from these findings are synthesized and implications and avenues for further study are proposed.

Table 2: Categorization of Students

Category description	Frequency (%)
Students answered the problem correctly initially	3 (14%)
Students answered the problem incorrectly initially, were presented with a correct solution, and were UNABLE to understand the correct solution	**7 (31%)**
Students answered the problem incorrectly initially, were presented with a correct solution, and were ABLE to understand the correct solution	**9 (41%)**
Students answered the problem incorrectly initially; did not revisit the problem	3 (14%)

Nic – Initially incorrect, unable to make sense of division by 4 factorial. Nic originally arrived at the incorrect Expression 3. In his work he had written down Gp 1, Gp 2, Gp 3, Gp 4 (see his work in Figure 1**),** although he did not reference them in his answer. In fact, his discussion revealed that while he wrote different group numbers, he interpreted the problem correctly (that the groups were to be indistinguishable), saying that the question was asking about a situation, "where you're just splitting them into the groups and then that's it." Given his proper interpretation of the problem, the fact that he wrote down group numbers is noteworthy. He stated that he did so simply to "keep an order" in his head, but he did not seem to realize that this work suggested that he was unintentionally treating the groups as distinguishable.

> *Interviewer:* Okay. Cool, the Group 1, Group 2, Group 3, Group 4, did that help you in that counting process, or why did you distinguish between Group 1, Group 2, Group 3, Group 4?
> *Nic:* All it really did was to, basically I have 20 choose 5, so that gives me a group, is basically what I was thinking of, so I need to make sure I subtract those kids off for the next possible

group… So it was basically just helping me keep an order on where I was at in the process, so, it was more keeping an order for me in my head.

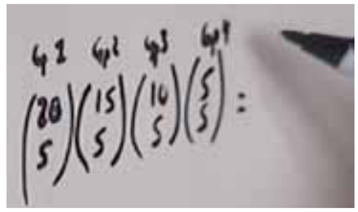

Figure 1: Nick's Group Labels Above Each Binomial Coefficient

When Nic revisited the problem and was given the correct Expression 1 to evaluate, he was unable to explain the division by 4 factorial. There was evidence that the unintended distinguishability of the groups seemed to be a key factor in his inability to reconcile the division by 4 factorial. In Nic's thinking, his process of writing down the labels for the groups was simply organizational, and he did not realize that by performing the multiplication, he was actually employing a counting process with implicitly ordered stages. The excerpt below provides evidence for why Nick might not have recognized that multiplication has implied ordered stages. He intimates that the binomial coefficient, the "choosing," already indicated that, "you're not permutating [sic]." This suggests that Nic felt the issue of order (and not making the groups distinguishable) was already handled in his answer to the problem.

Nic: In how many ways can you split a class of 20 into 4 groups of 5?...I think that [his initial answer, Expression 3] is still right. Because when you do this choosing, when you do this already takes into account that you're not permutating. This one [the alternative solution, Expression 1] you're doing it twice. So this [Expression 1] is probably undercounting I think.

There is further evidence that Nic intended for his labeling of the groups as helping him keep track of things, focus on groups and not students. However, he did not recognize that there was an implicit distinguishability in his answer through the multiplication. Additionally, he did not notice that by saying there was a Group 1, Group 2, Group 3, and Group 4, he was implying that there was a first, second, third, and fourth ordered stage to his process.

Interviewer: Okay, now in your solution you had written a Group 1, Group 2, Group 3, Group 4 above it. What was that?

Nic: Uh, that was just show that I was doing it by groups rather than students, that we have 4 different possibility – 4 different groups that the students could go into that wasn't anything for them to be – the groups weren't labeled or anything, that's just knowing that you have to split 20 things into 4 spots, rather than actual names.

Even after spending significant time on the problem, Nic was ultimately not able to understand or explain the correct Expression 3. Nic's work on the Groups of Students problem shows an instance of a student who initially answered the problem incorrectly, and who was unable to make sense of the division by 4 factorial, even when the correct answer was presented to him (he was one of seven such students). In seeing this struggle, what comes to light is the fact that there was confusion for Nic about whether his multiplication somehow already caused the groups to be distinguishable and ordered in some way. His inability to see this is addressed further in the Discussion section.

Owen – Initially incorrect, able to make sense of division by 4 factorial. Owen had initially generated Expression 4, and his explanation highlights the sequential order in which he came up with the answer. When asked why he did not write the final term of choosing 5 of 5 students, Owen said, "There's just one way to do that, there's only one. They're just sitting there in their group already."

Owen: Ah, interesting. 4 groups of 5. Well, this one I mean, it seems pretty easy to pick the first group, you know, I have 20 people, choose 5…Great. Well, this one I feel kind of friendly with,

'cause then whoever I chose, I have 15 people left, I just choose 5…I only have 10 people left, and I choose 5. There's 5 people left. That's how I'd count it. I don't know if that's right or not.

When Owen returned to the problem later in the interview, he was given Expression 1 to evaluate. Upon reading it, he said, "I don't understand why they would divide by 4 factorial I guess…I'm immediately confused by that." After taking some time to think about what might have been going on, Owen was eventually able to explain what had happened in the problem, and why he would indeed need to divide by 4 factorial. To do so, Owen appealed to a particular outcome, showing how the incorrect Expression 4 could lead to an overcount. Owen started to write an example, but not wanting to write out 20 objects, he instead considered splitting up 8 students into four groups of two. He wrote down ABCDEFGH, and he wrote the corresponding solution that he would have done with 8 students, $\binom{8}{2}\cdot\binom{6}{2}\cdot\binom{4}{2}\cdot\binom{2}{2}$. He then took different colored pens, and, as he explained the solution below, he underlined each binomial coefficient with a different color (pink, red, orange, and green, respectively; see Figure 2).

Owen: I'm going to order my selections, because I think of them as happening in some order. So it's like this first [draws a pink line under $\binom{8}{2}$], and I'm going to do this second [draws a red line under $\binom{6}{2}$], this third [draws an orange line under $\binom{4}{2}$], and this fourth [draws a green line under $\binom{2}{2}$], right

Figure 2: Owen's Color Coding of the Outcome

Then, as seen in the excerpt below, Owen recognized that when he chose the groups of students to be AB, CD, EF, and GH, he could have chosen them in some order; the colors represented a particular order in which he chose that division of the 8 people. As he talked about choosing a pair of students, he drew a color under that pair. He drew lines under AB, then CD, then EF, then GH in that first example, and he drew lines under AB, then EF, then GH, then CD in the second.

Owen: What if, when I first chose 2 students, I picked, I'm going to make it really obvious, A and B [draws a pink line under AB]… Cool, then I have 6 remaining. Then I pick C and D [draws a red line under CD]. Oh, what if I have 4 remaining? Oh I'm going to pick these 2 [draws an orange line under EF, then draws a green line under GH].

He then noted that he could pick the same division of 8 people (AB, CD, EF, GH) in another way, and he drew colors above the letters to represent picking the pairs in a different order. This time, he drew AB first, then EF, then GH, then CD.

Owen: Well, that's one way to count, pick 'em, right? Color, change the colors drawn above again, so…you can pick the pairs in different orders… To make it obvious I'll draw the colors. Look, I'm just drawing the same exact pairs, different colors up here…To symbolize that if I did

this, I could have picked him, this same pair twice, right, but second I could have picked CD or I could have picked EF…And then third I could have picked EF or GH…And last, CD or GH, the remaining pairs…Same exact pairs, counted twice here [Expression 4], counted only once here [Expression 1] because you're dividing out the ordering of the pairs.

Owen is an example of a student who initially got the problem incorrect, but who was ultimately able to make sense of the correct Expression 1 when it was presented to him. Owen's work on this problem is noteworthy because it shows how he identified a particular outcome (or an outcome in a smaller case) in order to address the overcounting issue and ultimately decide which expression was correct. His work suggests that he recognized that the multiplication was imposing order on his process, producing distinguishable groups. He cleverly used a color-coding scheme to indicate exactly how the same division of 8 students was actually counted more than once by the incorrect expression. His work here suggested that focusing an example in the set of outcomes of the smaller problem allowed him to complete the problem correctly.

Discussion and Conclusion

The above findings show examples from two groups of students who faced varying levels of success on the Groups of Students problem. As they struggled with making sense of the division by 4 factorial in Expression 1, evidence emerged about an important aspect of students' thinking about multiplication. In particular, the Groups of Students problem revealed that students did not always recognize that multiplication necessarily implies ordered stages. The ordered stages are difficult to detect in this particular problem because the problem counts fairly abstract objects, and because the problem solution includes binomial coefficients. For instance, Nic assumed that his initial solution took into account the fact that he wanted the groups to be indistinguishable, and he assumed that the multiplication of the binomial coefficients did not imply ordered stages. This was presumably partly because of the presence of binomial coefficients (which tend to signify order *not* mattering), causing him not to realize that, whether he intended to or not, the act of multiplying was bringing order into the problem. This contributed to his failure to realize that he was really incorporating order, and, thus, to answer the problem correctly, he needed to account for the groups being distinguishable by dividing by 4 factorial.

The Groups of Students problem brings to light significant issues regarding multiplication and order, both of which are absolutely fundamental aspects of counting. Students' poor success on this problem (both initially, and even after being given the correct answer) suggests that multiplication is not as well understood as might be expected. Thus this problem highlights an important issue involving multiplication and suggests that this implied order in multiplication is something that should receive more explicit attention among students who are learning to count. The findings also suggest a way to fix this issue, however. Owen's work, for instance, suggested that while he initially could not understand the division by 4 factorial, it was an appeal to a particular outcome that enabled him to make sense of why the division was necessary. Indeed, there were 9 students who initially got the problem wrong but were ultimately able to justify the division by 4 factorial. For all 9 of them, they used particular outcomes (in a manner similar to Owen) to come to understand the correct solution. The role of outcomes in identifying an overcount contributes to a growing body of evidence (Author, Date) that outcomes provide a productive perspective for counters to emphasize. Thus, more can be done in helping students articulate how the multiplication counting process actually generates outcomes, and by tying multiplication to outcomes productive and correct conceptions of multiplication can be strengthened, particularly in the context of counting. In examining students who were unsuccessful, problematic ways of thinking emerged that could be suggestive of broader issues as students count, especially pertaining to a lack of understanding of implied ordered stages in multiplication. In examining students who were successful, a particularly productive way of thinking arose, as students drew upon the set of outcomes to effectively reconcile and explain a key

mathematical issue. These students were able to articulate how the multiplication and the order were interacting in the incorrect Expression 3 to generate some outcomes more than once.

Pedagogically, students may benefit from engaging with problems like the Groups of Students problem, which raise subtle aspects of important counting concepts like multiplication and order. Multiplication cannot merely being seen as a trivial, taken-for-granted process, but rather teachers must strive to develop deep multiplicative reasoning in students, explicitly tying properties of multiplication to counting processes.

This paper describes the learning trajectory for Early Equations and Expressions (EELT), one of the 18 learning trajectories presented at www.TurnOnCCMath.net, developed to interpret the Common Core Standards for Mathematics based on research on student learning. The EELT is foundational for introducing concepts of early algebra and setting the foundations for the most advanced mathematical ideas in the later grades of schooling. The theoretical framework and research literature that the unpacking was based on are presented by giving examples from the descriptors of the standards.

Keywords: Expressions, Equations, Standards, Learning Trajectories

Learning Trajectories and the Common Core Standards for Mathematics: TurnOnCCMath.net

The Common Core State Standards for Mathematics (CCSS-M) (CCSSO, 2010) have been adopted by 45 states and the District of Columbia. Major goals include strengthening students' mathematical conceptual understanding, weaving eight key mathematical practices throughout mathematical instruction and learning, and bringing U.S. educational standards to par or better with education in countries whose preparation of students in mathematics is stronger than that of the U.S., based on international assessments (CCSSO, 2010). The CCSS-M represents a major effort to improve the coherence in learning expectations across states. The new standards include significant changes in depth, emphasis and timing of instruction in numerous topics. Some topics are introduced earlier, some later, than in previous standards from various states, and several with more intensive or expanded treatment (e.g. early number and operations; ratio and proportional reasoning; statistics and probability).

How then to translate the intent of the new standards into instructional practice, to interpret the CCSS-M in ways that strengthen students' conceptual development? Research on student learning by mathematics educators during the past 20 years or more has generated *learning trajectories* (LTs) as an organizing framework for student conceptual growth (Clements & Sarama, 2004; Confrey et al., 2009; Simon, 1995). Depicting student learning of major mathematical ideas over time, LTs describe student prior knowledge of particular ideas, and networks of instructional experiences that support students in transiting likely intermediate states of understanding on their way to robust domain goal understanding (Confrey et al., in press).

Learning trajectories can provide a framework for organizing the instructional core (Confrey & Maloney, 2011)—that spectrum of instruction, instructional practices, enacted curriculum, and classroom discourse and assessment that comprise the learning environment that children experience—to focus on the consistent development of student conceptual understanding over time.

[1] On October 22 of 2013, PME-NA committee was informed of a mistake in authorship. Therefore, the paper authorship herein differs from the version of this paper included in the PMENA 2013 Conference Proceedings that were posted on the conference website on Monday, October 21, 2013. The authors of this paper listed here are correct as of Thursday, October 24, 2013.

The CCSS-M calls for incorporation of "research-based learning progressions detailing what is known today about how students' mathematical knowledge, skill, and understanding develop over time" (CCSSO 2010, p. 4). Our research priorities are to bring to bear the research on student learning to support educators in interpreting the CCSS-M and support practical instructional implementation of the CCSS-M.

We have constructed 18 learning trajectories that cover all of the K-8 CCSS-M standards (http://www.turnonccmath.net) (Confrey et al., 2011; Confrey, 2012). A hexagon map of the CCSS-M was created as a visual model for navigating the connections among major topics and standards and illustrating learning trajectories within the standards. Each learning trajectory (LT) comprises descriptors that incorporate the Common Core Standards into text- and graphics-based descriptions of student movement from naïve to more sophisticated mathematical understanding. The descriptors identify (1) conceptual principles, (2) student strategies and representations or *inscriptions* along with misconceptions; (3) meaningful mathematical distinctions and multiple models; (4) coherent structure or schemes of reasoning as topics become more complex; finally, (5) bridging standards that are added to provide conceptual continuity for more fully articulated learning trajectories than could be provided in the compact CCSS-M. The iterative development of these learning trajectory descriptors, and their continual improvement and strengthening based on feedback and review, have been described previously (Confrey, 2012). In this paper, we describe in more detail the learning trajectory for Early Equations and Expressions (EELT).

Early Equations and Expressions Learning Trajectory

Algebra "encompasses the relationships among quantities, the use of symbols, the modeling of phenomena, and the mathematical study of change" (NCTM 2000, p. 37). By linking these topics to, and developing them simultaneously with, topics of early mathematics, the aim of early algebra in elementary schools is for students to establish the foundations for development of algebraic reasoning in middle and high school (Carraher et al. 2007). The main goal of algebra is for students to learn how to form generalizations by seeing the "general through the particular" and "the particular in the general" (Mason et al., 2005), to shift students' focus "from thinking about relations among particular numbers and measures toward thinking about relations among sets of numbers and measures, from computing numerical answers to describing and representing relations among variables." (Carraher et al., 2007, p. 266). For competency in algebraic reasoning, student learning must encompass and coordinate several different "big ideas" such as generalized arithmetic, functional thinking, the concept of equality, and the concept of a variable (Blanton & Kaput, 2011; Carraher et al., 2008; Carraher et al., 2007).

The goal of the EELT was to describe the development of students' reasoning about patterns and the early foundations of functional relationships (Section 1, "Exploring Patterns and Their Relationships"), equality and equations (Section 2, "Exploring and Solving Equations"), and expressions, including variables as quantities that vary (Section 3, "Working with Expressions"). These interrelated concepts span grades K through 7, concurrently during many of the grades, with standards from the Operations and Algebraic Thinking and the Expressions and Equations domains of the CCSS-M. Other topics important in the foundation of algebraic reasoning are covered in other TurnOnCommonCoreMath LTs: Inequalities and more advanced notions of functional thinking are emphasized in the Linear and Simultaneous Functions LT; operations including inverse operations, and properties are explored in detail in the Addition & Subtraction, and Division and Multiplication LTs, and ratio, rates, and proportional reasoning are developed in the Ratio and Proportion and Percents LT. Explicit connections among these and the EELT are made, where appropriate in each of these LTs. The EELT contains a total of 17 CCSS-M and 6 Bridging Standards, with their corresponding descriptors. The following sections describe the unpacking of the EELT as it was

developed and presented in www.TurnOnCCMath.net.

Section 1: Exploring Patterns and Their Relationships

Section 1 describes the development of student reasoning in identifying repeating and growing patterns, and the characterization of relationships between two patterns. The CCSS-M introduces arithmetic patterns in Grade 3 (Standard 3.OA.9), but does not explicitly treat geometric patterns, which are also a type of growing pattern. Repeating patterns can act as the basis for introducing growing patterns, because they are foundational for expressing initial generalizations of rules, functional relationships, proportional thinking, and number theory (Threlfall, 1999; Warren, 2005; Zazkis & Liljedahl, 2002). The CCSS-M introduces shape patterns in Grade 4 (Standard 4.OA.5), however, research has demonstrated that non-numeric patterns such as pictorial, verbal and symbolic should occur in earlier grades to help students recognize generalization in relationships that are "independent of the numbers or objects being operated on" (Warren, 2005, p. 759). Building on such insights, the learning trajectory therefore incorporates introduction of students first to non-numeric patterns (both repeating and growing) and then to numeric patterns (both repeating and arithmetic/geometric); we added four bridging standards to support these (Bridging Standards K.EQX.A, 1.EQX.A, 1.EQX.B and 2.EQX.A).

We also discerned a systematic scheme for pattern exploration (Figure 1), an example of *coherent structure* (element 4, above). For each type of pattern, student understanding is strengthened through first (a) identifying the terms and the core unit, (b) extending the pattern to subsequent terms, (c) identifying missing terms, (d) debugging mistakes, (e) recognizing common structure among patterns (i.e. the pattern 2, 4, 6, 8, … has the same structure as the pattern 86, 88, 90,…) and finally (f) creating new patterns from a given core unit and initial element.

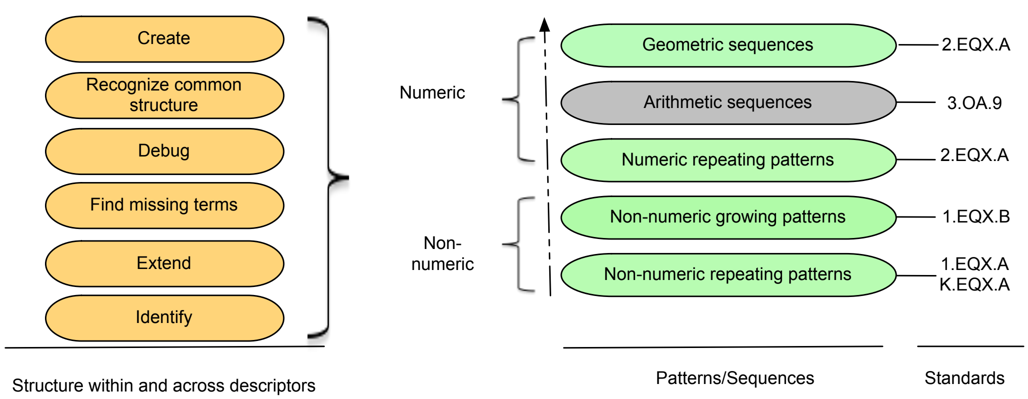

Figure 1: CCSS-M Standards in Grey and Bridging Standards in Green

A more sophisticated description of patterns, identifying a rule for a given pattern in standard 4.OA.5 (i.e. given the pattern 2, 7, 12, 17, … students identify the rule as "Add 5"), supports the second goal of this section, namely the identification and characterization of relationships between two patterns (Standard 5.OA.3). A correspondence description for two patterns expresses a rule that relates corresponding value pairs of two patterns. A foundation of the development of correspondence rules is a covariation relationship, which explains how the values of two patterns change simultaneously (Blanton & Kaput, 2011; Confrey & Smith, 1991, 1994, 1995). The distinction between covariation and correspondence relationships can be introduced through contextual problems, for example the following: "A roadrunner, being pursued by Wile E. Coyote, runs 3 meters every two seconds. Make a graph that describes the distance the roadrunner travels in relation to time. Predict the roadrunner's location after 5 seconds." The learning trajectories highlight

multiple representations: e.g. for characterizing functional relationships, the use of diagrams, tables, graphs, and dynagraphs (Figure 2).

Time (s, seconds)	**Distance m (meters)**
0	0
2	3
4	6
6	9
8	12
10	15

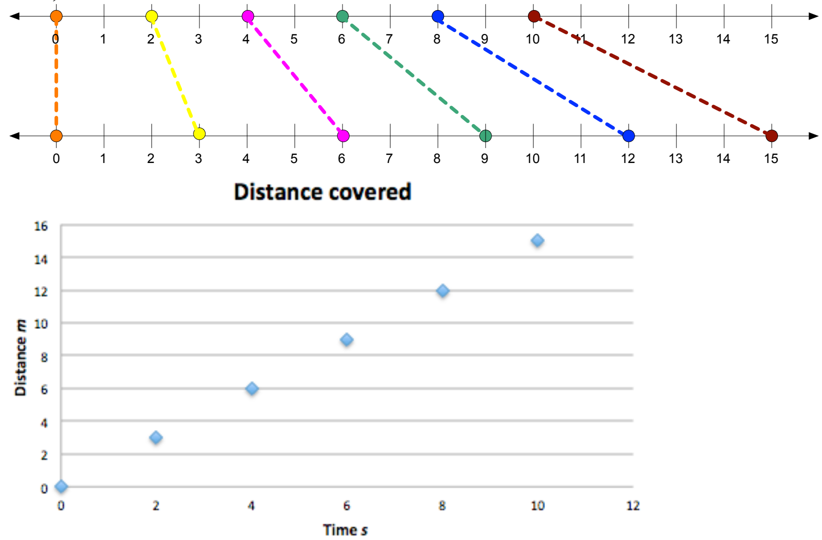

Figure 2: Table, Dynagraph and Graph as Representations

The two patterns in this example covary: values in the first column increase by 2 while values of the second column increase by 3. A correspondence description here delineates a rule that describes one of the sequences in terms of (dependent on) the values of the other: any value to distance covered by the roadrunner (m) is $^3/_2$ times the corresponding value of the time (s) in seconds. Students in 5th grade are not expected to write a symbolic equation for this type of relationship. However, they are expected to extend the patterns and identify the rule (correspondence). Studies have shown that students are capable of reasoning about covariation and correspondence relationships as early as first grade (Blanton, & Kaput, 2004; Martinez & Brizuela, 2006; Stephens et al., 2012). By 5th grade in the EELT, students have experience exploring both covariation and correspondence relationships and a variety of arithmetic and geometric sequences, all of which lay a strong foundation for the development of ratio and functions in middle school (Carraher & Schliemann, 2007; Zazkis & Liljedahl, 2002).

Section 2: Exploring and Solving Equations

The goals of Section 2 focus on a) understanding the concept of equality and solving equations and b) the concept of a variable as representing a single unknown. Equality is a pivotal concept with multiple meanings. It is key to development of a progressively sophisticated understanding of and flexibility with equations. It is developed from a way to make the equations "balance," to determining which equations are true or false, leading to the more sophisticated solving of equations (Carpenter, & Levi 2000; Carpenter et al., 2003; Van de Walle et al., 2013). The aim is for students to recognize that the equal sign signifies a claim that the quantities or expressions on either side of the equal sign represent the same value; this serves as a foundation for creating equivalent algebraic expressions at the higher levels of the learning trajectory.

The CCSS-M introduces the meaning of the equal sign in equations in Grade 1 (Standard 1.OA.7). Before formal introduction to the equal sign and writing equations, students learn to model the equality of (a) two additive parts (which can be joined) and their sum, and (b) equipartitioned parts (which can be reassembled) and their original collection or whole. To link students' prior understanding of joining and separating in counting (Samara & Clements, 2009; Nunes & Bryant, 1996; Fuson et al., 1983; Piaget, 1965) and equipartitioning and reassembly (Confrey et al., 2009) to

the concept of equality, we added a preceding bridging standard (1.EQX.C) that contains multiple well-known ways to concretely model equations, such as unifix cubes, counters, and drawings. Balance scales also serve as visual models for equations: children use different combinations of quantities to represent and achieve balance (equality) and to show equivalence between an original collection and all of the corresponding fair shares reassembled (Baroody & Ginsburg, 1983; Van de Walle et al., 2013). Balance diagrams (Figure 3) anticipate the balancing of equations in algebra (Herscovics & Linchevski, 1994). Another visual model for equations is the "bar model" (Figures 4a/b), in which children use different combinations of horizontal bars to establish claims of equal lengths or to show equivalence between a collection of items and the reassembly of equipartitioned fair shares (Fong Ng & Lee, 2009; Hoven, 2007). For example, students may recognize that a 12-inch paper strip shared among three people can be represented with 4-inch long strips per person, which can then be reassembled lengthwise to form the original 12-inch paper strip (Figure 4a). They may also demonstrate that the three fair shares of 4-inch strips all have the same length (Figure 4b). We conjecture that as students coordinate such models with the writing of equations, they reveal misconceptions about the role of the equal sign, such as using it as an operator symbol (Carpenter & Levi, 2000; Carpenter et al., 2003; Kieran, 1981). Teachers can then, in a timely way, instructionally address such a misconception.

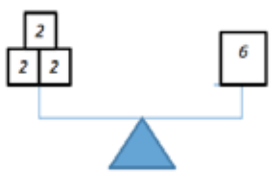

Figure 3: Balance Scale

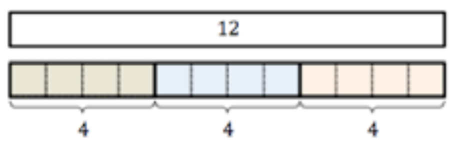

Figure 4a: Bar Model 1

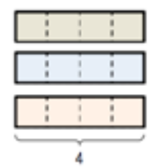

Figure 4b: Bar Model 2

Following the writing of equations, students begin to solve equations with single unknowns. They progress from addition and subtraction equations to division and multiplication equations relating three whole numbers (Standards 1.OA.8 and 3.OA.4 respectively), move to equations that involve four whole numbers (3.EQX.A, bridging standard added) and then to the more sophisticated solving of two-step word problems using all four operations in equations (Standard 3.OA.8). For the solving of all the types of equations above, the EELT includes four different strategies suggested by research (Carpenter, & Levi 2000; Carpenter et al., 1996): a) *substitution* of different values, including checking to see if the two sides of an equation have equal value; b) using *models* to illustrate equivalence, such as rearranging arrays (i.e. 6 x 2 is equal to 3 x □); c) applying inverse operation (as in "fact families"), such as rewriting 35 ÷ 7 = □ as 7 x □ = 35 to solve; and d) applying known properties (commutative property of addition and identity) to solve problems, such as recognizing that the equation 1 x □ = 35 ÷ 7 can be simply □ = 35 ÷ 7 through application of the identity property (1 x □ = □).

Section 3: Working with Expressions

Section 3 of the EELT has goal understandings of a) distinguishing between variable as representation of a single unknown value and variable as a quantity that varies, according to context, b) using variables in different contexts to represent quantities, and c) identifying and generating equivalent expressions at a more advanced level.

Students first encounter the *variable* as representing a single unknown value in equations (Section 2) but now broaden the concept to represent a quantity that varies, in exploring expressions (Standard 6.EE.2.a). Studies have shown that students of an early age can represent quantities that vary (Carraher et al., 2007; Marum et al., 2011). Again, multiple representations support

strengthening student understanding: variables should be represented in many forms including multiple letters, shapes, and symbols, in part to avoid the development of misconceptions and prototypes such as believing that letters are general referents (i.e. *h* stands for height of multiple people) (MacGregor & Stacey, 1997) and that different symbols can have the same value (Carpenter et al., 2003). Contextual problems such as the following, from Brizuela & Earnest (2008), support distinctions: "Raymond has some money. His grandmother offers him two deals: *Deal 1*: She will double his money. *Deal 2*: She will triple his money and then take away 7. Raymond wants to choose the best deal. What should he do? How would you figure out and *show him* what is the best to do? Is one deal *always* better? Show this on a piece of paper." Generating expressions for these problems, students recognize that a) a variable can represent a parameter whose value determines the characteristics or behavior of other quantities [i.e. if m is the value money above, then Deal 1 is $2\bullet m$ and Deal 2 is $(3\bullet m)$-7], b) while the value of a parameter can vary, its value is always fixed in the context of a specific problem, and c) the same variable used in expressions related by context must represent the identical value, but different variables may represent the same value or different values (Blanton & Knuth, 2009-2013). By exploring which deal is better to take, students distinguish between an equation or inequality being true for *all* values of x, and for *some* (or only one) values of x.

While exploring equivalent expressions, students typically identify two expressions as equivalent if, for any value substituted for the variable, the values of the two expressions are equal (Standard 6.EE.4). This implies that a single counterexample (a value for the variable that yields unequal values of the expressions) demonstrates the expressions' non-equivalence (Carpenter & Levi, 2000). Students express numerous common misconceptions and errors when simplifying expressions, but by substituting values for the variables before and after simplifying, and looking for counterexamples, they are able to strengthen their understanding and improve their accuracy. This experience is critical for generating equivalent expressions, bringing many of students' skills with operations, in a variety of contexts, together with their work in algebra, to explore and demonstrate the power of algebra as a generalized solution method (Standards 7.EE.1 and 7.EE.2), thereby advancing their algebraic reasoning and problem-solving abilities.

Implications and Discussion

The EELT builds on previous research on how students' thinking progresses within patterns and sequences, equations, and expressions, and is foundational for the development of their algebraic thinking. Aiming to show the progression of "big ideas" within the CCSS-M, the LT maintains the grade level of each mathematical idea as it is presented in the CCSS-M (for instance, not introducing the variable as a quantity that varies until 6th grade, despite research showing that this can be done earlier) while providing bridging standards to fill gaps in the CCSS-M for instructional continuity and a coherent structure (e.g. introducing repeating patterns and geometric sequences). Blanton and Knuth (2009-2013) have suggested five curricular learning progressions for algebra education: a) equality, expressions, equations and inequalities, b) functional thinking, c) variables, d) generalized arithmetic, and e) proportional reasoning. Ongoing research such as theirs will provide additional fundamental insight for revising the EELT and other learning trajectories of TurnOnCCMath.net. Interpretation and implementation of the CCSS-M using learning trajectories can spur strategic critical areas of further research into student learning of mathematics, and contribute to constructive critique of the CCSS-M, both of which will lay the groundwork for systematic revision of the CCSS-M in the coming years.

THE CONSTRUCTION OF TRIGONOMETRIC AND INVERSE TRIGONOMETRIC FUNCTIONS

Rafael Martínez-Planell

Angel Cruz Delgado
University of Puerto Rico at Mayaguez
angel.cruz14@upr.edu

This study uses APOS Theory to study students' construction of the sine and cosine functions and their inverses. The conjecture of the constructions students would need to do in order to attain a process conception of these functions is tested by using semi-structured interviews with a group of 11 undergraduate students. Analysis of the interviews suggests a small number of basic mental constructions that students would need to do, that account for observed difficulties, and that hence would need to be stressed during instruction.

Keywords: High School Education, Instructional Activities and Practices, Algebra and Algebraic Thinking

The trigonometric functions and their inverses are important enough in mathematics and its applications to warrant more attention than they have received in the mathematics education research literature. In this paper we use APOS Theory to discuss how students may construct the sine and cosine and their inverse functions. Our research questions are:

1. What basic mental constructions can be conjectured that students need to do in order to have a process conception of the sine and cosine functions and their inverses?
2. Which of the conjectured basic mental constructions students can be observed in students' work when they use these functions in problem solving activities?
3. Which of the conjectured basic mental constructions seem to be lacking when students use these functions in problem solving activities?

Background

While there is an increasing amount of publications in the mathematics education research literature that deal with trigonometry, due to space restrictions we will not include a review of that literature but rather only mention and refer to three articles.

Bagni (1997) observed in an example that a sizable number of students have trouble finding all solutions of $\sin x = 1/3$. Also, for some students the value of the trigonometric functions have no clear sense at real numbers other than the integer multiples of $\pi/6$, $\pi/4$, and $\pi/3$. He relates these observations to the effect of the didactical contract on students. Weber (2005) argued that an instructional path where trigonometric operations are understood as geometric processes to be both physically performed and reflected upon may result in deeper conceptual understanding of these operations as functions. In her doctoral thesis, Brown (2005) examined the transition from right triangle trigonometry to trigonometry in the coordinate plane, and from there to the graphical representation of sine and cosine. She found that many students had a fragmented or incomplete understanding of sine and cosine, with many not connecting the right triangle, unit circle, and graphical representations. While in her exploration and discussion she seems to favor starting with a ratio definition of trigonometric function and moving from there to the unit circle, we adopt a different approach, as the emphasis of our study falls heavily on the unit circle representation. This will enable us, among other things, to obtain information on students' notion of inverse trigonometric functions, a topic omitted by Brown. While we agree

with many of her observations and recommendations, our approach leads us to consider different issues and constructions in students' learning of trigonometry.

Theoretical Perspective

Action-Process-Object-Schema (APOS) theory (see for example, Dubinsky and McDonald, 2001), is a well known theory and hence we only give a brief description. An action is a transformation of a mathematical object by individuals, following explicit step by step instructions or using a memorized fact or procedure. An action is perceived as external by the individual. As an action is repeated and the individual reflects on the action it can be *interiorized* into a process. As a process, the transformation may be done mentally; it may be reversed and may be coordinated with other processes. The outcome of the process may be imagined without actually having to perform it. In contrast to an action, a process is perceived as internal. When a person reflects on actions applied to a particular process, the person may become aware of the process as a totality. In this case it is said that the process is *encapsulated* into an object. A mathematical schema is a coherent collection of actions, processes and objects, and other previously constructed schemas, which are synthesized to form mathematical structures utilized in problem situations (Baker, Cooley, & Trigueros, 2000). It is important to note that although it might be thought that in APOS theory there is a linear progression from action to process to object and then to having different actions, processes, and objects organized in schemas, this often appears more like a dialectical progression where there can be partial developments, passages and returns from one to another conception (Czarnocha, Dubinsky, Prabhu, & Vidakovic, 1999). What the theory states is that the way a student works with diverse mathematical tasks related to the concept is different depending on his or her conception.

The application of APOS theory to describe particular constructions by students requires researchers to develop a genetic decomposition – this is a conjecture of specific mental constructions students may make in understanding mathematical concepts and their relationships. Some clarifications are pertinent. The initial genetic decomposition is based on the researchers' knowledge of mathematics, teaching experience, history of the mathematical development of the concept, and any available data. A genetic decomposition for a concept is not unique, it is a model of how a concept may be constructed; different researchers can develop diverse genetic decompositions for a particular concept, but, once one is proposed, it needs to be supported by research data from students. Frequently, data may reveal mental constructions which students make that are different from the ones conjectured, as well as specific conjectured constructions that cause special difficulty for students. This may lead to the development of learning activities for students to help them make the necessary constructions and/or to a revision of the genetic decomposition to better reflect the constructions that students actually make. Eventually the cycle of data gathering, classroom activity implementation, and genetic decomposition revision, stabilizes in a genetic decomposition that serves both to describe the constructions that students actually make as well as to guide instruction.

While we will not include our complete initial genetic decomposition in this paper, we will outline some of the constructions, particularly some specific processes that form part of it.

The Process $t \uparrow P(t)$

One of the processes needed in the construction of sine, cosine and their inverse functions is the process of taking a given real number *t* (preferably not an integer multiple of $\pi/4$ or $\pi/6$, at the beginning) and locating the terminal point $P(t)$ of the unit circle that corresponds to *t*. Building this process requires repeating and reflecting upon actions such as those suggested by

Weber (2005), a version of which appears in Figure 1. A student able to imagine doing this without having to explicitly do it can be said to have the process denoted $t \to P(t)$.

Symmetries of the Circle as a Process

The student will also need to interiorize into a process the action of given a point $P(t)$, represented geometrically or as an ordered pair, finding the other three corresponding points $P(-t)$, $P(t+\pi)$, and $P(\pi - t)$ on the unit circle, in the respective representation, geometrically or as ordered pairs. Further actions that students need to interiorize include: given *t*, locate any point of the form $P(t+n2\pi)$, $P(-t+2n\pi)$, $P(t+\pi+2n\pi)$, $P(\pi-t+2n\pi)$ as well as $P(t+n\pi/2)$, for integer *n*, and find their coordinates, given those of $P(t)$. This process plays an important role in the reversal process used to define inverse trigonometric functions. We will refer to it as the "symmetry of the circle" process. Explicit use of these symmetries while solving trigonometric equations may be regarded as evidence that a student has interiorized these actions into a process.

Process of Projection

Now the sine and cosine functions may be defined by following the $t \to P(t)$ process with a process of projection onto the *y* axis (to define the sine function), or onto the *x* axis (to define the cosine function). We will refer to the concatenation of these two processes as the definitions of the basic trigonometric functions. A process conception requires being able to imagine this concatenation. What we are stressing is that the definitions of the sine and cosine functions require two separate steps: given a real number, assigning to it the coordinates of a point on the unit circle, and then following that process with a projection onto the appropriate axis.

While it is true that formally, anyone defining the trigonometric functions starting with a unit circle approach would at least implicitly use the above decomposition, we are underscoring here that there are three main ideas that would merit being stressed during instruction: the process of given a real number, assigning to it a point on the unit circle; using the symmetries of the circle; and that the definition of the sine and cosine functions follow a two step process (locating a point on the circle followed by a projection). In keeping with Bagni (1997) and Weber (2005), the above constructions need be done for real numbers, not only for integer multiples of $\pi/6$ and $\pi/4$. After having interiorized the process of definition of the sine and cosine functions, the process may be coordinated with the use of technology, allowing students to, among other things, compute values of the sine and cosine functions with the precision afforded by the technological artifact used.

Reversal of the Process of Projection

Now, the process of definition of the basic trigonometric functions will need to be reversed in order to define the inverse trigonometric functions. Note a process conception of the definition is needed in order to reverse it. Hence one needs a process of reversal of the appropriate projection. The process starts with a number which is either an *x* or *y* coordinate of a point on the unit circle, produces a geometric representation of the number as a point on the *x* or *y* axis, and then produces the geometric representation on the unit circle of the corresponding point or points having that *x* or *y* coordinate. The symbolic representation of those points as an ordered pair of real numbers could be obtained coordinating the points obtained from the projection reversal process with the equation of the unit circle, or, equivalently, with the Theorem of Pythagoras.

After reversing the projection, to obtain one or two points (as geometric entities) on the unit circle, the process $t \to P(t)$ needs to be reversed in order to obtain a number *t* determining one of the points. This reversal needs to be an interiorized mental process, and may be constructed

with activities analogous to the ones in Weber (2005), or equivalently, using the unit circle and pipe cleaner as suggested by Figure 1. This process reversal may be done with geometric arguments in the case of special values. Observe that memorizing tables of special values will only result in an action conception, not in the needed mental process. The action of obtaining one real number t corresponding to a given point $P(t)$ of the unit circle, will now need to be coordinated with the symmetry process to produce all real numbers t determining the corresponding points.

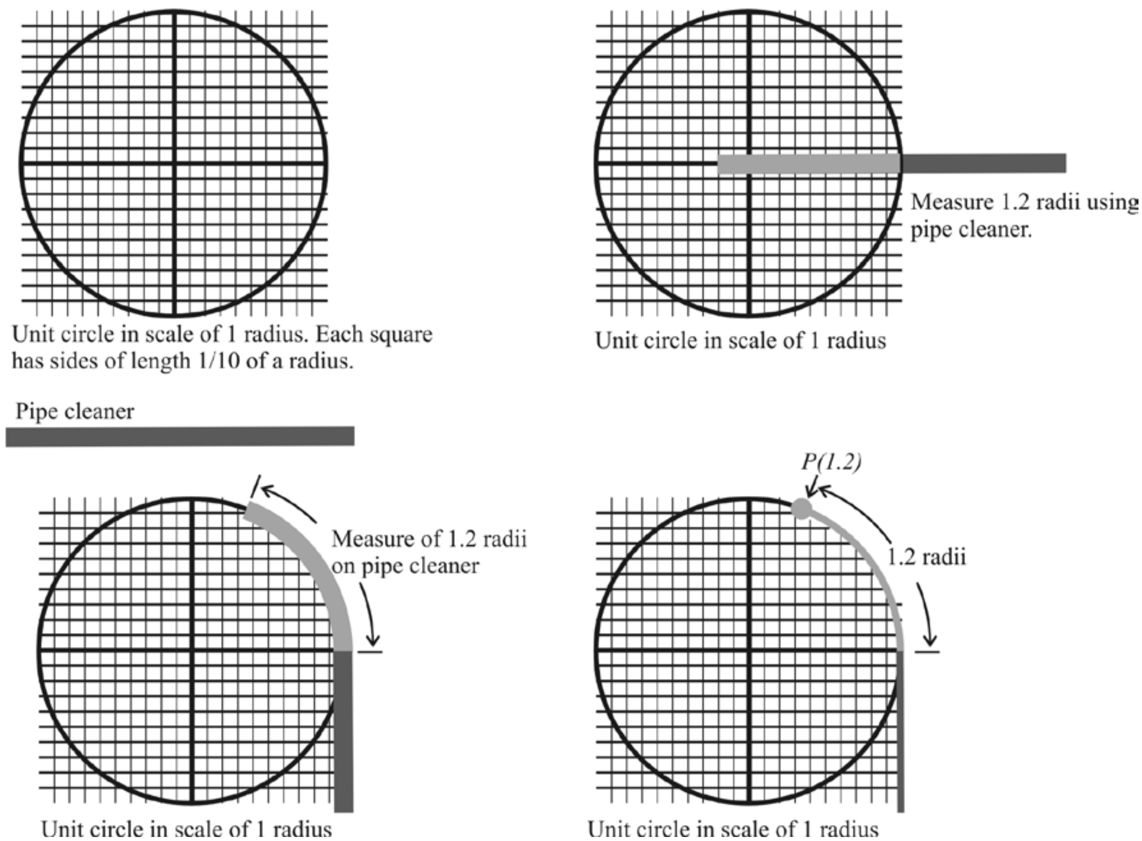

Figure 1: Using a Pipe Cleaner to Locate Point $P(1.2)$ on the Unit Circle.

The chain of actions that starts with a number (represented as an x or y coordinate), goes on to identify the point or points on the unit circle having that number as an x, or respectively y coordinate, and then identifies all the real numbers corresponding to the point or points on the unit circle, may be interiorized into a process that we call reversal of the definition. This process starts with a coordinate and produces the collection of all real numbers corresponding to the points on the unit circle (one, two, or none) having that coordinate. By its nature, this process does not define a function.

The Process of Range

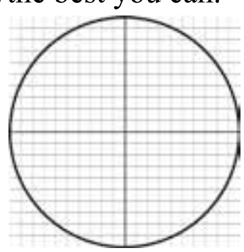
The action of coordinating the above definition reversal process with the function schema is needed in order to have the inverse trigonometric functions. In particular, the coordination of the process of reversing the definition with, what we will call, the process of Range (of the corresponding inverse trigonometric function), is interiorized into a process of inverse trigonometric function. As will be seen, an action conception of Range (having memorized the

range of the inverse sine and cosine) will not enable students to build a process conception of inverse trigonometric functions. We conjecture that building a process conception of Range requires explicit attention and will not follow from the mere statement of a formal definition. Students will need to interiorize actions that explore ways of restricting the domain of the sine and cosine functions so that the resulting function is one to one and the restricted domain is connected and as large as possible. These actions should include both, unit circle representation and the graphs of these functions. The process resulting from the interiorization of these actions would allow students to argue for the need and also the convenience of restricting the domains of sine and cosine as they normally are. Otherwise, students will be constrained to having an action conception of Range as a memorized fact. The coordination of the process of exploration of possible restrictions of the domains of sine and cosine with the concept of range of an inverse function is what we call the Range process (of an inverse trigonometric function). Once students have a process of inverse trigonometric functions (coordination of definition reversal and Range), it may be reinforced coordinating it with the use of technology through actions that explore and compare the mental constructions that have been made.

Method

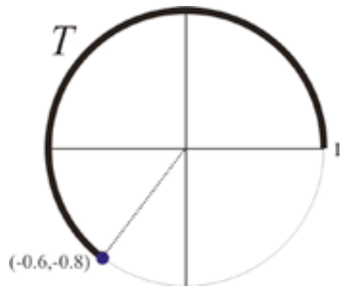
The study took place at a mid-size public university in Puerto Rico (approximately 14,000 students) with a large science and engineering component (at least 60% of the students). Semi-structured interviews were conducted with 11 students in order to test a preliminary genetic decomposition. Of the students interviewed, 3 were above average, 5 average, and 3 below average according to their professor. Students were chosen this way in order to be able to observe a wide range of different behaviors when engaged in mathematical tasks. All students were enrolled in the same section of a precalculus course, where they used a traditional textbook (Stewart, Redlin, and Watson, 2011) and received traditional instruction. The interviews were recorded and transcribed, and records of students' written responses were kept. The interviews were analyzed independently by the researchers, by comparing student constructions to those predicted by a preliminary genetic decomposition. They were then discussed, and differences were negotiated. Student performance on the interview questionnaire was graded and scores were kept. Seven of the 12 interview questions were pertinent to the present article:

1. Use the unit circle in the figure and the pipe cleaner [a string, as in Figure 1] to approximate the value of $\sin(1.2)$ the best you can.



2. Use the unit circle in the figure and the pipe cleaner to approximate the value of $\sin^{-1}(0.8)$ as best you can.
3. Given that $\sin\left(\frac{10\pi}{7}\right) = -0.974927912$. Find $\sin^{-1}(-0.974927912)$.
4. Draw on a unit circle *all* terminal points $P(t)$ corresponding to numbers *t* of the form $4t = \frac{\pi}{3} + 2n\pi$, *n* an integer, and that are between 0 and 2π.

5. Find all solutions of $\cos(t) = -\frac{1}{2}$ in $[0, 2\pi)$.
6. Find all solutions of $\sin(t) = -\frac{3}{5}$.
7. We start on point $(1, 0)$ on the unit circle and travel counterclockwise on the circle a distance T, as shown in the figure below, ending at point $(-0.6, -0.8)$. What is the value of T?



Results

The Process *t* ↑*P(t)*

Recall this is the process of assigning a point on the unit circle to any given real number. Of the interviewed students, 8 of 11 had difficulty assigning a point to a number.

When originally asked to estimate the value of sin(1.2) using the pipe cleaner and the unit circle, and after having shown Ricky how to use the pipe cleaner to measure arc-length on the unit circle (as in Figure 1):

Interviewer: Is there some way you can use the pipe cleaner to estimate $\sin(1.2)$?

Ricky: I don't think so, I don't know… It is finding 1 and 1.2 [he is referring to finding $P(1)$ and $P(1.2)$] and I'm finding it difficult … well, sine is y, … drawing a line towards y [referring to the y axis]

Later on, after a long intervention where the interviewer helped Ricky locate $P(1.2)$:

Ricky: So, sine of 1.2, what comes to mind is … when one says that sine is y … is drawing a line to the y axis and that would give me a value.

Note that Ricky has difficulty with the $t \to P(t)$ process (seems to have an action conception) but seems to be aware of the need to project.

Symmetries of the circle as a process

Six of the 11 interviewed students had difficulty using the symmetries of the circle. Maria, the student with the second best performance in the interview questionnaire (71%) is an example of a student not having interiorized the use of circle symmetries as a process. In Problem 7, after using a calculator to compute $\cos^{-1}(-0.6)$ she needs to find the corresponding point on the third quadrant:

Maria: Use this angle … to do something, the answer then is… add pi.

The Process of Projection

We saw the case of Ricky, who had not interiorized the $t \to P(t)$ process but seemed to recognize the need to follow this with a projection onto the y axis in the definition of the sine function. In the case of Diana, it is the other way around. Diana was the only student not showing any difficulty with either the $t \to P(t)$ process or the process of symmetries of the circle, and by far the student having the best all around performance on the interview

questionnaire (92%). Three instances where she failed to immediately obtain a correct response had to do with her failure to do the corresponding projection:

Diana: [In problem 1, after correctly using the pipe cleaner to locate $P(1.2)$ without any help] In this case, sine of 1.2 is equivalent to, the *y* value of a terminal point.

Interviewer: How would you estimate $\sin(1.2)$? You may use the pipe cleaner as you see fit.

Diana: I don't know if to apply $a^2 + b^2 = c^2$ … I don't know, nothing comes to mind …

Latter when doing Problem 7, Diana again fails to project onto an appropriate axis (in order to use either $\cos^{-1}(-0.6)$ or $\sin^{-1}(-0.8)$):

Diana: … What is the value of *T*? … one would need to find … the measure of the angle between pi and the terminal point and add to it … ay! It seems to be so easy!

Interviewer: What are you thinking?

Diana: I'm thinking in … it doesn't occur to me …. [She was eventually able to use right triangle trigonometry and the inverse tangent function to successfully complete the problem]

Reversal of the Process of Definition and Inverse Trigonometric Functions

All 11 students interviewed failed at one point or another, to apply an inverse trigonometric function. Indeed, of the 12 questions in the interview questionnaire, the four problems in which students achieved the lowest overall score were problems directly dealing with the inverse sine or inverse cosine functions (36% in Problem 2, 13.6% in Problem 3, 31.8% in Problem 6, and 30% in Problem 7). In the interviews we observed students who showed difficulty using an inverse trigonometric function due to different reasons: not having interiorized the $t \to P(t)$ process, or the projection process, or the circle symmetries, or the Range process.

For example, Gina seems to not have interiorized the projection into a process (in problem 2), hence she shows difficulties with its reversion:

Gina: Well I have that sine represents the *y*... [She goes on to measure 0.8 correctly on the pipe cleaner but locates $P(0.8)$ rather than a point with *y* coordinate equal to 0.8].

Gina is then directed to compute $\sin^{-1}(0.8)$ on the calculator but she still fails to relate this to the 0.8 on the *y* axis:

Gina: … the angle of 53 degrees would give the point $P(t)$.

Interviewer: I'd like to see that angle, where is it? [Referring to the unit circle in the figure used for problems 1 and 2.]

Gina: Well, it would be around here, I would draw an approximate radius, since I have nothing to measure it with [Even though a horizontal line crossing the *y* axis at 0.8 is part of the figure, she does not use it or refer to it].

Another common observation is that students may be able to do an action or process of reversing the definition when working in the context of special values, like Problem 5, and yet fail to use the process of reversing a definition in the more general context, as in Problem 6. Indeed, 6 students had problem 5, either partially or completely, correct and problem 6 completely incorrect. This suggests that the actions being interiorized by students should be carefully chosen to include the general context as well as the context of special values.

It is important and interesting to notice that none of the students used a drawing in trying to make sense of problems 5 and 6 (solving $\cos(t) = -1/2$ and $\sin(t) = -3/5$). This stresses the need and importance of the actions that give explicit attention to the geometric representation of the unit circle when reversing the process of definition of sine and cosine.

Observed results sustain the need to help students develop the conjectured constructions.

Summary

In order to construct a sine or cosine function, students need a process ($t \to P(t)$), where they start with a real number and assign to it a point on the unit circle, and they need to follow that process with a projection onto the appropriate axis. Hence, we argue that instruction would need to emphasize that the definitions of these functions follow a two-step process and it would also need to emphasize that the definition applies to any real number, not only special values. It was found that the two steps in this construction, the process ($t \to P(t)$) and the projection, are two independent processes that account for many student mistakes in problem solving situations.

We also observe that the construction of an inverse trigonometric function requires essentially, reversing a definition. Reversal of the definition process, consists of reversing the projection by starting with an x or y coordinate of a point on the unit circle and ending with one or two points on the unit circle, followed by reversing the process $t \to P(t)$ and coordinating with the symmetries of the unit circle to obtain all real numbers determining a point on the unit circle having the given x or y coordinate. In particular, this suggests that instruction would need to emphasize activities that lead students to interiorize actions exploring the symmetries of the circle. It was also conjectured that an inverse trigonometric function results from the coordination of the definition reversal process with the appropriate Range process. It was found that student' difficulties, particularly in problems dealing with inverse trigonometric functions resulted from lacking some of the aforementioned processes. It could also be deduced that instruction would need to aim at having students build a process of Range for the inverse trigonometric functions, relating unit circle and graphical arguments of why the sine and cosine functions are restricted they way they are when defining inverse trigonometric functions. It was observed that not having this process, students are left with a memorized fact, hence an action conception of Range, making it difficult to recall and use the range of an inverse trigonometric function in problem situations. It was clear that the notion of an inverse trigonometric function is a complex construction that accounts for many student mistakes in problem solving situations.

Much work still needs to be done: developing activities to help students do the conjectured constructions, class testing, performing a second round of interviews including students' use of graphical and numerical methods in problem solving, and refining the genetic decomposition accordingly. Nevertheless, the conjectured process constructions seem useful in describing student behavior in problem solving, in organizing research, and in helping guide instruction.

DEVELOPING PROCESSES FOR LEARNING HIGH SCHOOL MATHEMATICS

P. Janelle McFeetors
University of Alberta
janelle@mcfeetors.com

High school mathematics students often complete homework and study for unit tests without support to consider how these actions could contribute to their mathematical learning. Learning to learn mathematics invites students to bring into view how they learn mathematics. The constructivist grounded theory study reported in this presentation describes how grade 12 students inquired into the systemically defined and externally imposed learning strategies that they perceived as static and superficial. The Framework for Developing Processes for Learning Mathematics *illuminates the complexity of becoming aware, incorporating suggestions, verbalizing possibilities, and (re)forming intentions to shape personal processes for learning. Viewed as dynamic and authentic, the processes for learning mathematics students developed shaped them as learners who made sense of mathematical ideas.*

Keywords: High School Education, Learning Theory, Metacognition

Mathematics education reforms have emphasized students' personal development of mathematical ideas (National Council of Teachers of Mathematics, 2000; Western and Northern Canadian Protocol, 2008). Absent from these reforms and from experiences in many high school mathematics classrooms is explicit discourse about the processes of learning – both identifying the strategies students use to learn (e.g., homework, taking notes, test preparation, study groups) and then how to individually adapt those strategies. While study how-to books abound (e.g., Coles, White, & Brown, 2003; Ooten & Moore, 2010; Peltz, 2007), the publications are didactic in their approach and divorced from the particular contexts of learning mathematics, rather than working from individual students' current intentions and processes for learning mathematics.

Within mathematics education, research using the psychological construct of metacognition (Brown, 1978; Flavell, 1976) has supported improvement in students' mathematical thinking (e.g., Hamilton, Lesh, Lester, & Yoon, 207; Schoenfeld, 1987). This research report extends the work of these cognitively-based studies to address the complexity of learning which view mathematics students as persons in the process of becoming. Research in mathematics education has identified successful students as those who understood their personal learning processes (Dahl, 2004; Smith, 1999), and this study extends this recognition to explore students' *development toward* becoming capable mathematical learners.

Purpose of the Study

The empirical research being presented in this research report is part of a larger study that addressed the question: *What is the nature of students' learning when they engage in conversations to shape their personal processes of learning high school mathematics?* The purpose of the study was to understand how high school students learn to learn mathematics. Results of the larger study demonstrate that students were able to see themselves as capable learners of mathematics because of a learning-based orientation in the world that simultaneously grew as they developed approaches to independently learning academic mathematics. This research report will focus on one facet of my theorizing about students' experiences of learning to learn mathematics in order to closely examine how students shifted from the use of

systemically-imposed learning strategies to personally-developed processes of learning. Novak and Gowin (1984) help tease out the distinction between “learning and knowing. They are not the same. Learning is personal and idiosyncratic; knowing is public and shared.” (p. 5) In taking up this notion of learning, I am proposing an alternate perspective on students’ engagement in high school mathematics classes, namely the possibility for inviting students to shape processes for learning mathematics in ways that are personally dynamic and authentic.

Mode of Inquiry

Constructivist grounded theory [CGT] (Bryant & Charmaz, 2007; Charmaz, 2006, 2009) returns to the symbolic interactionist root of grounded theory while looking through a constructivist lens as an interpretive process for inquiring into dynamic phenomena. Within this postmodern orientation, theory is constructed by a researcher on a provisional basis and contingent to the context. There is an “emphasis on processes, making the study of action central” (Charmaz, 2006, p. 9), recognizing that shifts in people’s actions and experiences signify growth and changes within the people and their interactions. The researcher, seen as a subjective knower, is immersed in the research setting while co-constructing qualitative data with participants. As data is analyzed abductively, the researcher moves from rich empirical data through levels of abstraction toward developing a mid-range interpretive theory. Processes like coding, memoing, categorizing, theoretical sampling, saturation, and sorting are offered as “systematic, yet flexible guidelines for collecting and analyzing qualitative data … rather than formulaic rules” (Charmaz, 2006, p. 2). The reflexivity of the researcher results in explicating the theorizing as both process and product enabling other researchers to apply and extend the work.

The focus of this research, students’ experiences of learning to learn mathematics, is supported by CGT’s framing to notice and interpret the growth of individuals. Grounding interpretation in students’ experiences, rather than applying extant theoretical frameworks, supports the uniqueness of the study in attending to the development of mathematical learners. Theoretically, constructivism is the predominant epistemological orientation to the teaching and learning of mathematics (Bishop, 1985; Davis, Maher & Noddings, 1990), often used in conjunction with symbolic interactionism for mathematics education research (Cobb & Bauersfeld, 1995; Sierpinska, 1998; Voigt, 1994). The use of CGT responds to the growing importance in theorizing to make progress within the field of mathematics education (Hiebert, 1998; Proulx, 2010).

Research Context and Participants

The study was situated in an academically-focused suburban school in a city in Western Canada. Thirteen grade 12 students who were taking a pure mathematics course volunteered to participate in the study. Their pure mathematics courses were offered in a didactic format where the teacher lectured, students copied out worked solutions to examples, and then worked through similar questions independently as homework. The students were enrolled concurrently in a course, *Mathematics Learning Skills*, that provided support for their mathematical learning. In the class, students worked on homework and requested help from the teacher. Within the *Learning Skills* course, I assisted the teacher in coaching students to improve their approaches to learning mathematics while simultaneously collecting data. The teacher also participated in the study to provide contextual information and offer her perspective on emerging analysis.

Data Collection

Data collection occurred over four months. After observing each class, I wrote detailed field notes of students’ (inter)actions in the class and descriptions of daily informal conversations with the teacher. Students took part in bi-weekly interactive journal writings (Mason & McFeetors,

2002). They responded to prompts about the progress of their learning strategies and I replied in order to interact with their ideas, modeling thinking about learning and fostering a relationship with each student. Students were placed into one of three small groups with a focus on developing a learning strategy as a group (transitioning from notes to homework, developing big ideas from completed homework, and studying for unit tests by creating summary sheets). Each small group met for three to five sessions of approximately 30 minutes each. The students also participated individually in two informal interviews as a retrospective look at their progress in shaping their learning strategies. Each interview was approximately 30 minutes and occurred halfway through the study and at the end. While the interactions were intended as multiple sources of data, they also afforded students the opportunities to develop processes of learning to support their mathematical learning and to notice improvements in learning. Providing these opportunities was framed by Dewey's (1938/1997) notion of experience which is characterized by continuity and interaction and where activity is transformed into experience through the reflective act.

Data Analysis

Using line-by-line coding and the constant comparative method (Glaser & Strauss, 1967), data analysis involved the development of codes for students use of learning strategies across all forms of data. The codes, such as "do questions" and "see the process", remained close to the students' words and were refined through several passes through the data. The codes were stored in a spreadsheet which enabled parsing codes to create initial categories. Names of categories, such as "becoming aware" and "incorporating suggestions", are descriptive of the students' actions and abstracted from the data to highlight the process-based nature of learning to learn mathematics. I constructed the *Framework for Developing Processes for Learning Mathematics* through the interpretive act of theorizing by exploring the relationships of the categories. The categories and framework will be described in the results section below.

Perspective

Rather than using an interpretive framework, I adopted Blumer's (1954) notion of sensitizing concepts to "merely suggest direction along which to look … providing clues and suggestions" (pp. 7-8). Drawing on Blumer's work as a symbolic interactionist responds to the misconception that grounded theory studies begin atheoretically. Rather, the sensitivities of the researcher – what the researcher is drawn to attend to because of her/his experiences of conducting research, scholarship in the field, and interests – are acknowledged, explored, and employed as a starting place in the collection and analysis of data. The purpose of a CGT research project is not to refine sensitizing concepts but to interpret the participants' experiences.

My sensitizing concepts developed out of two of my related research projects. In one project, high school students' success in non-academic mathematics was interpreted as an emerging of voice, where students came to say things about themselves as mathematical thinkers and learners with the intention of (re)forming their identity (McFeetors, 2003, 2006). In another project, students' trajectories of learning, through choices of high school mathematics and science course, indicated that students selected among mathematics courses in relation to their identity as learners, and their ways learning within courses was connected to who or what they perceived as sources of mathematical knowledge (Mason & McFeetors, 2007). The four sensitizing concepts are: intentions, voice, identity, and relationships with sources of knowledge. After each explanation, I provide examples of literature for those who desire a more thorough discussion.

Intentions are internal constructs which give meaning to actions. These thoughts and desires arise from attention to previous experiences and to the consequences of actions, often through

reflection. When students are intentional, they are acting with the intentions they have formed and hold, to move toward a particular aim. This aim, as an end-in-view, is fluid and the method of moving toward it contains ambiguity. Intentions point to what students want to do or achieve and a notion of how they might go about doing. So, intentions both mark an aim and a process. (See Bereiter & Scardamalia, 1989; Searle, 1983.) *Voice* points toward having space and confidence to say things and to do so, a reflective stance to make sense of experience through conversation, and being deeply implicated in actively shaping oneself. Voice is dynamic concept, one in which a student's voice is continually being refined through experience and through the voicing of the experience and growth of self. (See Baxter Magolda, 1992; Confrey, 1998.)

Identity is an understanding or sense of self. It is a dynamic processes, where the (re)forming of identity is continually undertaken through experiences and relating with others. While occasionally marked by large shifts, (re)forming identity is more often seen as shaping a way of being in the world and understanding that way of being. Shaping an identity is the ongoing negotiation of a student's relationship with mathematics, learning, schooling, others – identity is malleable and complex. (See Britzman, 1994; Sfard & Prusak, 2005.) *Relationships with sources of knowledge* – such as teachers, peers, and textbooks – point to students' beliefs about knowing and coming to know (epistemological stances) which are inextricably connected to the experiences of learning mathematics. The relationships could include dependence, independence, and interdependence and are often illustrated through examples of where authority in mathematical knowledge lay and through the choice of approaches to learning. (See Belenky, Clinchy, Goldberger, & Tarule, 1997; Chickering & Reisser, 1993.)

Results

In students' first journal, they listed the prescribed ways to learn mathematics, such as study, review, copy notes, work with others, and do homework. Learning strategies were ways students were told by their teachers to learning mathematics and were labels that did not probe the steps students would need to take to enact the learning strategies. The uniformity in naming learning strategies arose from the systemically defined characteristic of learning strategies, that school as a normative structure has systematized these procedures without consideration of these particular students. Teachers, as actors in the system, compelled students to use the learning strategies through their authoritative stance, resulting in externally imposed ways to learn content. Although the students desired to succeed in mathematics class and acknowledged that these learning strategies should support that success, they struggled to implement them to any effect. Vanessa illustrates this in her first journal when she writes "I tried reading my math notes when I get home. But I find that when I try to do the homework and understand the notes, I've already forgotten how and what to do by the end of the day."

The unquestioning implementation of learning strategies demonstrated the students' lack of intentions and personal investment in procedures espoused by the school system. Students perceived the learning strategies as being static and superficial. Teacher demands, especially for notes and homework, led students to use the strategy as prescribed even if they did not see it as supporting their learning – the strategy was static both in its implementation and lack of contribution to learning mathematics for understanding. The learning strategies contributed in a superficial form of learning (memorization of mathematical procedures), glossed over the challenges of learning, and viewed one way of learning as equally effective for all students. However, not only were the learning strategies static and superficial, but these characteristics positioned the students as static persons whose learning was also superficial. Through the use of simplistic learning strategies, students did not have opportunities to be changed by deep

engagement in a learning process and mathematics. They continually saw themselves as ineffective learners and prioritized the surface goal of high marks. Against this backdrop, the students and I began to explore the ways they were struggling to learn academic mathematics.

This exploration is better characterized as an inquiry into learning strategies. My interpretation of the students' engagement resulted in the *Framework for Developing Processes for Learning Mathematics*. The four facets of the framework provide an emerging picture of how students engaged in inquiring into learning strategies, moving toward the development of personal processes of learning mathematics. These forms of engagement in shaping ways of learning mathematics represent the categories constructed from and grounded in the students' data. Being enacted simultaneously and in an interrelated fashion, *becoming aware*, *incorporating suggestions*, *verbalizing possibilities*, and *(re)forming intentions* were the ways in which students shaped how they were learning mathematics through their *Learning Skills* class and the procedures for data collection for the study.

The students were *becoming aware* of the learning strategies, the limitations of those strategies, and the personal nature of their mathematical learning through their inquiry. Kylee, who had previously created a system of cue cards for learning terms in biology, noticed their limitation for mathematics through her second journal, "I realize how much of my time I waste making Q-cards (sic) before my test when I could instead be studying them," and found an opening to refine an existing process of learning. Shane's insight in our first interview, "I would focus on learning how these numbers work and now I guess how the numbers work is a concept in itself, but I never thought of it that way" signals a new awareness that his mathematical learning could fit his identity as a conceptual learner. The growth in students' awareness was situated in a space where their voices could be heard and valued, even in its tentative state.

As the students shaped ways of learning in the small group sessions, they were *incorporating suggestions* from their peers and from me. Kylee described my interactions with her as "you weren't telling me to do something or getting mad because I did that on a math test. You were just encouraging", as I offered alternatives and worked from students' current capabilities in learning mathematics. Drawing on both peers' and my support, Elise exemplifies the notion of incorporating suggestions by actively modifying suggestions (as opposed to compliantly implementing teachers' learning strategies). In her recording "big ideas" at the end of a homework assignment, Elise asserted that "what we wrote down here broke down what it actually meant … So, I understand what to do when I have a question" showing that she had adapted my suggestion of identifying one or two main concepts from a lesson which I had suggested. Elise also modified Danielle's approach of using sticky notes on summary sheets as "I kind of like the way she does it, but I think it works better for me the way I do it." While the students listened to the ideas of others, they recognized that they themselves were expert sources of knowledge about how they learned.

When students deliberated on how to modify ways of learning and put their ideas into words, they were *verbalizing possibilities* for ways to learn mathematics. Danielle demonstrated that sometimes these were internal conversations, where "I was just sitting on the bus, and I was thinking … how would I be able to separate my ideas and stuff." In my field notes I also recorded that "as Danielle handed in her fifth journal, she explained aloud how she would use different colors of sticky notes to represent different kinds of content such as definitions, formulas, and examples." After noticing that Danielle wrote "With [the] method I developed, my ideas are organized and laid out in a way that really helps me understand" in the journal itself, her oral utterance is an example of her first attempt to articulate for herself the details of a new

possibility for her process of learning at the end of a unit. As we worked together in a small group on this studying process, Danielle not only refined her explanations for the use of sticky notes as an organizational technique, but used them to demonstrate how she connected mathematical ideas across a unit of content. The verbalizing of possibilities occurred both orally and in writing through my conversations with students and demonstrated that students, like Danielle, could be sources of knowledge for how they learn and perceived their voices as being valued in the learning context.

Students were *(re)forming intentions* for particular ways of learning mathematics as they moved away from the unquestioning use of learning strategies. Grace realized a memorization-based approach to academic mathematics was not sufficient, and explained in our first interview how she refined two processes of learning with the intention of developing mathematical understanding. First, the students' talk in her study group shifted from "how you got the answers" to "we discuss why you're doing it" when completing homework questions. While this shift supported Grace's growing belief about mathematics as a process, the intention she had for her collaboration with peers evolved from comparing answers to mathematical discussion. Second, in authoring various forms of notes, Grace explained she added on side notes – that were "in my words … [s]o it's easier for me to understand" – to the teacher's notes she copied down. She formed the intention of putting mathematical ideas in her own words which impacted all her processes of learning mathematics. The students' intentions developed out of shaping the learning process and increased the complexity of the process of learning. As students became aware that learning processes could be adapted to fit who they were as learners, the intention was not only how the process would support their mathematical learning, but they also became intentional about learning to learn mathematics.

As students inquired into the learning strategies they were told to use to learn mathematics, they were developing processes for learning. Examples of these processes of learning (juxtaposed with strategies in parentheses) included creating summary sheets (study), making and using cue cards (review), authoring various forms of notes (copy notes), collaborating with peers (work with others), and learning from homework (do homework). Processes for learning mathematics are ways in which students make sense of mathematical content and are developed by students in response the particularities of each one. In contrast to learning strategies, processes for learning were perceived by the students as being dynamic and authentic. A process of learning was dynamic because the students continued to shape it and noticed their peers doing the same. Additionally, process for learning supported students' construction of mathematical understanding, were the discipline of mathematics was seen as malleable and the content was of their own making. There was authenticity in the processes for learning, not only because the students were aware of the effectiveness of the processes but because they authored the processes and could describe the development of the processes. The students experienced growth as mathematical learners, a dynamic process, and came to have a nascent authorial stance as they saw themselves as personally developing their processes for learning.

Discussion

The *Framework for Developing Processes for Learning Mathematics* represents the complexity of students' learning when they engage in an approach that opens up space for them to develop processes of learning. This extends beyond the limits of how-to literature on studying to contribute to a way of being with students that supports their learning to learn mathematics. By explicating four ways of engaging in learning to learn mathematics, I hope to invigorate research into metalearning in mathematics education in order to refine these constructs.

This study is an example of an alternative research design which could serve to broaden approaches to inquiring into students' mathematical learning. Researchers may find the methods of data collection, which students found to be legitimate processes in learning to learn, useful in their research with high school students. Additionally, researchers may find CGT to be a methodological approach to research in mathematics education which holds much promise for theorizing informed by the experiences of students and teachers in schools.

Research continues to illustrate the important role of covariational and quantitative reasoning in the context of function and graphing. The same body of literature has emphasized that students and teachers often construct meanings for function and graphing that do not foreground these reasoning processes. In order to gain deeper insights into such meanings, we conducted clinical interviews with ten pre-service secondary teachers. In the present work, we illustrate the construct of shape thinking in relation to their graphing activity during the clinical interviews. We draw particular attention to the implications of shape thinking, including constraints generated by meanings rooted in such thinking, when confronted with non-canonical situations.

Keywords: Teacher Education-Preservice, High School Education, Algebraic Thinking

Students' function meanings remains a critical area of research in mathematics education (Oehrtman, Carlson, & Thompson, 2008), with a growing body of literature characterizing the role of covariational and quantitative reasoning in supporting students' function concept (Carlson, Jacobs, Coe, Larsen, & Hsu, 2002; Castillo-Garsow, 2012; Ellis, 2007; Moore, 2012; Thompson, 1994, 2011; Weber, 2012). For instance, Castillo-Garsow (2012) identified that the manner in which students' conceive quantities and how they change in tandem has serious implications for their images of exponential growth. Likewise, Moore (2012) and Weber (2012) illustrated the importance of students' attention to dynamic relationships between quantities in the context of trigonometric functions and two-variable functions, respectively.

Although it is apparent that quantitative and covariational reasoning are important for students' function concept, students' mathematical experiences typically lack a fundamental focus on such reasoning (Oehrtman et al., 2008; Smith III & Thompson, 2008; Thompson, in press). In turn, these students construct function meanings devoid of imagery that involves varying quantities' values. As cases in point, Thompson (1994), Goldenberg and colleagues (1992), and Weber (2012) documented that students have a tendency to conceive graphs as pictorial objects with various global properties that are not grounded in quantitative reasoning. Weber and Thompson termed such ways of thinking as *shape thinking* (Weber, 2012).

We extend the shape thinking construct by exploring pre-service secondary mathematics teachers' (PSTs') activity during clinical interviews (Goldin, 2000) designed to offer insights into their meanings, particularly in the context of graphing. Based on several classroom events that suggested PSTs engage in shape thinking, we designed interview tasks such that shape thinkers might face perturbations in their meanings. By generating such situations, we characterize shape thinkers' meanings, including constraints shape thinkers face when confronted with situations that are not supportive of shape thinking. Against the backdrop of our results, we discuss several implications of shape thinking and provide conjectures about the nature of students' mathematical experiences that contribute to shape thinking.

Theoretical Framing

When one speaks of meanings, he or she is speaking of a pervasive, yet complex and often ill-defined term (Thompson, in press). Thus, it is necessary that we provide a brief description of our use of the term *meaning*. Drawing on the works of several individuals who concerned themselves with epistemology

(e.g., John Dewey, Ernst von Glasersfeld, and Jean Piaget), we consider meanings to be constructions unique to an individual that organize her experiences. As Thompson (in press) described, and drawing on Piaget's description of understanding and meaning, the act of constructing meaning entails assimilation; to construct a meaning is to construct a scheme through repeated reasoning that enables one to organize her experiences.

Due to the assimilatory nature of meanings, meanings influence how an individual makes sense of her future experiences. But, we caution that claiming meanings are assimilatory does not imply that meanings are static cognitive structures to be applied as is. Rather, meanings become more and more stable through an individual repeatedly reconstructing these meanings to make sense of her experiences (Thompson, in press). Meanings remain viable as long as they continue to enable an individual to organize her experiences in a way that is internally consistent. In the case that a particular meaning and experience leads to a perturbation, an accommodation or reorganization is then necessary to reconcile this perturbation.

Graphing, Shape Thinking, and Quantitative Reasoning

Stemming from a study exploring calculus students' meanings for two-variable functions, Weber (2012) characterized shape thinking as, "an association the student makes with a function's graph. For example, a student might associate a function's graph with a particular shape with physical properties while another student might associate a function's graph with a representation of quantities' values" (p. 17). In the present work, we use the phrase *shape thinking* to refer to this first aspect in which an individual's meaning for a graph is inferred directly from the pictorial image and perceptual properties of the physical shape. In contrast to this form of reasoning, Weber deemed activity rooted in reasoning about covarying quantities as *expert shape thinking*. For clarity reasons and to avoid implying that shape think is necessarily developmental, we do not use the phrase shape thinking to refer to the act of conceiving a graph as an emergent representation of how two quantities vary in tandem.

To provide contrasting examples of shape thinking and reasoning about covarying quantities, consider a student tasked with determining the formula for the graph in Figure 1.

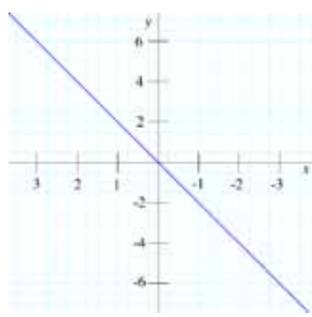

Figure 1: A Graph of $y = 2x$

When providing a formula for the above graph, a shape thinker may first associate the graph with a formula of the form $y = mx+b$ because she associates $y = mx+b$ as defining a line. From there, she may conclude that $m = -1$ by reasoning that m represents the tilt of the line and the line is downward sloping at a 45 degree angle with the horizontal axis. Lastly, she concludes that $b = 0$ because the graph passes through the origin. In such a solution (e.g., $y = -x$), the students' activity foregrounds previously defined properties that are tied to perceptual attributes of the shape (e.g., straightness and tilt).

To provide a contrast to the above solution, another student may approach the problem by identifying that for each point captured by the curve, the y-value is two times as large as the x-value, leading the student to conclude that $y = 2x$. As another example, the student may determine that the curve captures

paired values such that for any change in x, the change in y is two times as large, and since the initial value (e.g., when $x = 0$) for y is 0, then $y = 2x$. Whereas a shape thinker focuses on more global and pre-defined properties of the graph, essentially conceiving the graph "all at once" to determine the associated formula, these latter two solutions are generative in that the graph and its associated formula are conceived in terms of a dynamic relationship between quantities' values; the latter students' activities foreground a dynamic projection of points onto two axes to represent the quantities' values.

We agree with Weber's (2012) stance that shape thinking is not entirely bad. Shape thinking can support an individual in quickly inferring different representations and properties of a relationship conveyed by a graph (e.g., a line in the Cartesian coordinate system conveys a relationship that is also represented by $y = mx+b$). But, a problem arises when shape thinking is in the absence of underlying meanings tied to inferences about quantities that vary in tandem (Goldenberg et al., 1992; Oehrtman et al., 2008; Thompson, 1994; Weber, 2012).

Methodology

In order to better understand the nature and implications of shape thinking, we conducted semi-structured clinical interviews (Goldin, 2000) with ten undergraduate PSTs at a large university in the southeastern United States. We chose the PSTs on a voluntary basis. Each interview lasted approximately 90 minutes and all participants were given the same set of interview tasks. The PSTs were in their third undergraduate year, had already completed a minimum of two semesters of calculus plus two courses past the calculus sequence, and were currently enrolled in a functions and modeling course for PSTs. The course formed their first content course in the pre-service secondary mathematics teacher education program. We videotaped, transcribed, and then analyzed the interviews using conceptual analysis techniques (Steffe & Thompson, 2000) with a goal of characterizing the ways of thinking and meanings that supported their activity on the tasks.

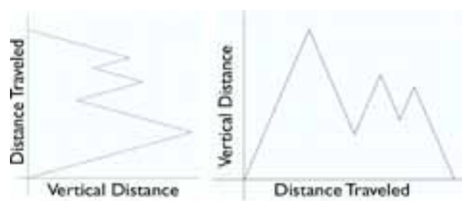

Figure 2: Debating Graphs

The choice of PSTs for this investigation was influenced by a variety of factors. First, our focus on shape thinking arose out of a classroom event during a previous year in the functions and modeling course. This event consisted of a debate that ensued as a group of PSTs argued whether two graphs with different orientations represented the same relationship (Figure 2). For some, the orientation of the axes and visual features of the graphs were significant components of their thinking leading them to maintain that the two graphs did not represent the same relationship; to these PSTs, the two graphs were visually different and thus had to represent different relationships. Based on this event, we anticipated that a subset of the following semester's PST cohort would rely upon shape thinking. Further, we chose to work with PSTs because their meanings matter in that they influence their teaching practices and their future students' learning (Simon, 2006; Thompson, in press). We hoped to better understand their meanings and subsequently improve teacher preparation based upon our understandings of their meanings. For instance, better understanding shape thinkers' meanings may provide insights into how to perturb their meanings and generate learning opportunities.

Task Design Example

When characterizing meanings, it's important that the researcher identify constraints in an individual's ways of operating, as these constraints aid the researcher in building more viable models of students' mathematics (Steffe & Thompson, 2000). In order to gain deeper insights into PSTs' meanings, we designed numerous tasks such that a shape thinker might encounter such constraints. As shape thinking is rooted in reasoning about pictorial objects in and of themselves, meanings rooted in shape thinking require that the situation conform to conventions upon which such meanings were abstracted. Thus, in our design of the tasks, we designed several non-canonical situations in order to better understand shape thinking by identifying how deep-rooted shape thinking may be, characterizing constraints engendered by shape thinking, and uncovering other meanings that that the PSTs used to reconcile problematic situations.

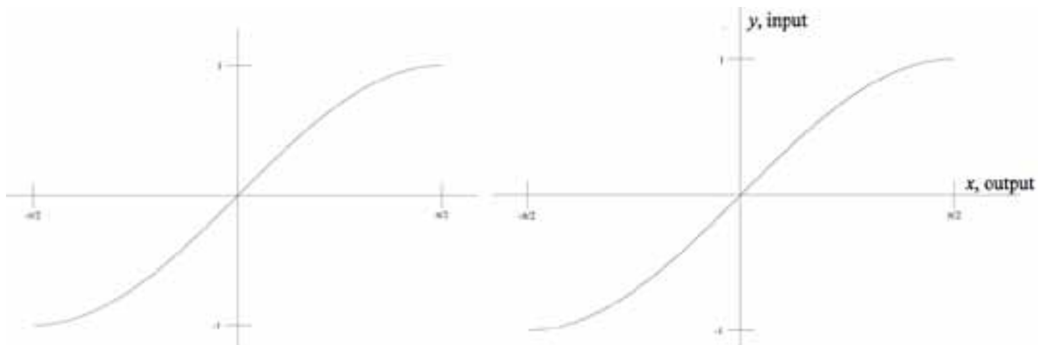

Figure 3: A Task to Investigate Shape Thinking

To illustrate one such task, consider the two graphs in Figure 3. The task proceeds: (i) first a PST determines a graph of the inverse sine function when given a graph of the sine function; (ii) the PST is then asked to comment on a graph (Figure 3, left) and prompt claiming that a student produced such a graph as an answer to part (i); (iii) lastly, the PST is presented with and asked to comment on a modified version (Figure 3, right) of the previous graph and a student explanation. The narrative provided with (iii) is, "*Well, because we are graphing the inverse of the sine function, we just think about x as the output and y as the input*. When giving this explanation, the student added the following labels to their graph. (*Student quote in italics*)."

We designed parts (ii)-(iii) to provide information about the PSTs' meanings in the context of a situation that was non-canonical (e.g., considering axes as simultaneously representing input and output quantities of two functions). To a shape thinker, a function's name and a particular pictorial object are inherently connected. For this reason, we conjectured that the solutions in parts (ii)-(iii) might be problematic to a shape thinker because each presents one curve as conveying *two* functions, $y = \sin(x)$ and $x = \arcsin(y)$ for $-\pi/2 \leq x \leq \pi/2$.

Results

As conjectured, the task described in the prior section revealed a number of instances that were suggestive of shape thinking. As a first example, consider Beth's (names are pseudonyms) response when determining a graph of the inverse sine function for part (i) of the task.

Beth: I should know this. Umm…I mean…(*pauses for 30 seconds and writes* $y = \sin(x)$).

Int: So how are you thinking about finding the inverse of that? Or the graph of the inverse?

Beth: (*Writes* $\sin^{-1} y = x$). So I mean, obviously it's just (*writes* $\sin^{-1} x = y$) which doesn't help at all. (*Laughs*). Umm, but, I'm thinking that it's either going to be something like…actually I'm kind of embarrassed because I really should know this.

In this exchange, Beth first attempted to recall a shape from memory (e.g., "I should know this"), an approach that was not successful. Beth then symbolically manipulated $y = \sin(x)$ into $\sin^{-1} x = y$, but obtaining this formula was not satisfying to Beth because her difficulty still lied within attempting to remember the shape of the graph (e.g., "I really should know this"). Following the above exchange, Beth made a few conjectures regarding the shape of the inverse sine graph, but as the discussion continued it became apparent that these conjectures were attempts to recall the graph from memory. Beth explained that she could not confidently determine an answer. We then progressed to parts (ii) and (iii) of the task to see how Beth would make sense of a posed solution to the problem.

Int: So a student came to you with that graph (*Figure 3, left*) claiming that it was a graph of the inverse sine function. What would you say to that? Could that be true?

Beth: Could that be true? Umm…(*thinks silently for 15 seconds*)…mmm, no. No.

Int: Why are you thinking no?

Beth: …I'm thinking this just kind of looks like…sine graph – like the plain sine graph. (*Laughs*). Which is going to be different. So, no…

(*Interviewer later gives Beth part (iii), Figure 3, right*).

Beth: I mean I guess what I'm like thinking about, like struggling with thinking is that like, like I don't know if, or if...an inverse function...like the graph of an inverse function, like, can't be the same as the original graph. Or can it? Like, I wouldn't think that it could. But maybe there's something I don't know. (*Sighs*).

Beth's responses and uncertainty in parts (ii) and (iii) are viable when viewed through the lens of shape thinking. Given this perspective, two different functions cannot be represented by the same graph because otherwise they would be the same function; a shape or curve has only one associated function name as a label. Thus, even though Beth was willing to admit there may have been something she did not know, she was unable to determine a way in which a student might conceive the graph as both the sine function and sine inverse function.

While Beth's perturbations appear to stem from her belief that different functions must have different shapes, another PST experienced conflict for apparently different reasons when responding to part (iii).

Megan: Oh, Um, Um. We just can't do that (*in response to Figure 3, right*).

Int: OK, say a little bit more.

Megan: (*Laughs*). It's not, that's not, his definition is not necessarily wrong. But you can't just label it like that. Um, why? Why can't you do that? I don't know, I feel like he's missing the whole concept of a graph…Like, I know you can call whatever axis you know if you are doing time and weight or volume whatever…But not necessarily with the sine graph. Like the sine graph's like a…it's a graph that everyone knows about…They are just missing the concept of graphing.

Whereas we did not identify an instance in which Beth focused on input and output quantities, Megan identified that the posed graph involved denoting the axes in various ways relative to input and output quantities. Megan seemed willing to accept reversing the roles of the input and output for some quantities such as time and weight, but not in the case of the given graph. We believe that her comment, "it's a graph everyone knows about" indicates that for the given graph, the input and output axes are fixed because that particular curve is designated as the sine function. Hence, changing the roles of the axes in the provided graph produces a conflict.

We see that both Megan and Beth experienced unique perturbations when faced with a non-standard approach to graphing the inverse sine function. Yet, underlying both perturbations is a similar phenomenon that rests in their uniquely associating the given curve with the sine function. Due to the nature of this association, the given curve could not also be considered as the inverse sine function, even in the case that a PST (e.g., Megan) acknowledged the possibility of considering different axes for the input and output quantities. In each case, because the curve was "known" by a particular label, it was not possible to be given another label.

Another form of shape thinking we observed was instances in which the PSTs' reasoning was focused on the global properties of a curve in ways that were not attentive to emergent quantitative

relationships. For example, Beth was presented with the following hypothetical student's graph of $y = 3x$ (note the non-standard orientation of the x and y axes in Figure 4).

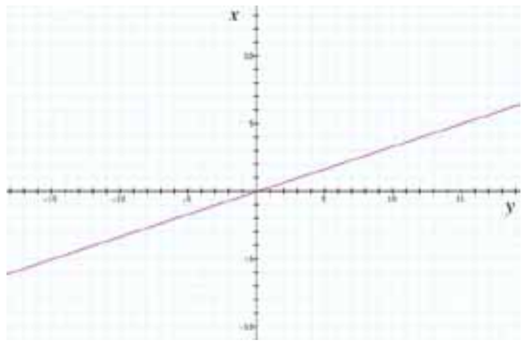

Figure 4: A Hypothetical Student's Non-standard Graph of $y = 3x$

> *Int:* How would you respond to the student or how might the student be thinking about this?
> *Beth:* Umm…like this (*spinning paper 90 degrees counterclockwise*). (*Laughs*). Like, because if you turn it this way then this (*traces left to right along the x-axis which is now in the horizontal position*) and this (*traces top to bottom along the y-axis*) and it would be still not right though (*spinning paper back to original orientation*).
> *Int:* And how would you respond to this student if they said, "Well here's how I'm thinking?"
> *Beth:* I guess…I mean the only way I can think of it is like this (*spinning paper 90 degrees counterclockwise*) and it's still wrong because this (*a line which is now sloping downward left to right*) is negative slope. So I would just, I would just explain to them, like the difference between the x- and y-axes and umm …show them like the difference between positive and negative slopes also. Because that's something that, like, when I was in middle school we, like, learned kind of like a trick to remember positive, negative, no slope, and zero (*making hand motions to indicate each*). Like where the slopes were. And it's stuck with me until now so it's important to know which direction they're going…

Beth's actions convey several instances of shape thinking. First, Beth's insistence that the line has a negative slope after rotating the paper 90 degrees counterclockwise to orient the x-axis horizontally and her reference to remembering slope-curve orientation pairs provides evidence that her meanings for slope are connected to a particular shape (e.g., a line sloping downward left to right implies negative slope). Beth's repeated moves to reorient the graph and her later rejection of the hypothetical student's solution is also evidence of her reliance on shape thinking. Beth's rotating of the graph was an attempt to achieve a conventional axes orientation, which would enable judging the solution against her image of the proper graph. Because Beth was unable to achieve an orientation compatible with her image of the appropriate graph, she maintained that the graph was "wrong" and described that she was not sure what the student did.

Although shape thinking was a common way of reasoning for many of the PSTs throughout the interviews, a few of the participants utilized other ways of reasoning to make sense of the given situations. For instance, in contrast to Beth's interpretations of the non-standard graph of $y = 3x$, another PST, Jacob, did not rely upon shape thinking. He instead made sense of the hypothetical student's work by conceiving the graph in terms of a quantitative relationship. After taking a few moments to inspect the graph (Figure 4, axes unlabeled), Jacob decided to consider a few of the paired values. This led him to conclude that the student was "plugging in" values on the y-axis (e.g., consider x from the formula as along the typical y axis). After seeing the student's work with the vertical axis being labeled as x, Jacob accepted the student's work as correctly conveying the relationship $y = 3x$. Although this type of

quantitative reasoning was rarely observed during the interviews, we include it as a contrast to the other results in order to highlight the implications of relying upon shape thinking as one makes sense of graphs.

Discussion and Concluding Remarks

Over the course of the interviews, the PSTs predominantly engaged in shape thinking, which is unsurprising given the body of literature documenting meanings of this nature (e.g., Thompson, 1994, in press; Weber, 2012). What was unforeseen was how the PSTs' meanings influenced their activity on problems that problematized shape thinking. The conflictions the PSTs faced during the interview tasks provide insights into the possible genesis of shape thinking. Instances of shape thinking became apparent when the given interview tasks broke common practices or conventions in school mathematics (e.g., axes orientation). As such, the PSTs' struggles can be partly framed as a consequence of constructing meanings inherently tied to these conventions and encountering interview tasks that did not conform to the conventions from which shape thinking was abstracted. The PSTs' propensity to engage in shape thinking highlights that such thinking had become an integral part of these PSTs mathematical meanings (e.g., meanings for the sine function, for inverse, and for slope). It follows that they likely had repeated experiences in which to (re)construct these meanings as viable. In other words, by repeatedly encountering situations that conformed to particular conventions, they abstracted meanings that were inherently tied to these conventions. For example, Beth's slope meanings were tied to shapes reliant on a particular axes orientation that is pervasive in mathematics.

Obviously mathematical conventions are critical supports to mathematical activity. But, a problem arises when meanings are tied to these conventions in ways that restrict one's ability to reconcile situations that are internally consistent but do not follow such conventions. For instance, the graph in Figure 4 is a quantitatively correct representation. Yet, several PSTs were not able to provide a viable explanation for the student's proposed graph because their meanings required that the graph be in a more conventional orientation. Such an outcome speaks to a possible drawback of mathematical conventions in the context of student learning; by repeatedly experiencing situations that conform to particular conventions, these conventions can become constraining aspects of student meaning. Then, as these students later become teachers, the conventions constrain how they may operate with their students and interpret student work.

Glasersfeld (1995) stated, "Actions, concepts, and conceptual operations are viable if they fit the purposive or descriptive contexts in which we use them" (pg. 14). The prevalence and deep-rooted nature of shape thinking among the PSTs in the study implies that their meanings had consistently been "purposive and descriptive" during their previous mathematical experiences. By breaking from common graphing conventions, the tasks in this study created situations in which shape thinking did not provide a viable solution. This problematized the PSTs' meanings, which would have generated teaching and learning moments in the classroom or another setting (e.g., a teaching experiment). Further research should explore how such tasks could be used to support students' development of meanings that entail reasoning with quantitative relationships. Additionally, further research is necessary to characterize possible implications of particular conventions in K-12 mathematics in the context of student learning.

MATHEMATICS STUDENTS TRANSITIONING INTO THE WORKFORCE: INFLUENCES ON CAREER CHOICE

Katrina Piatek-Jimenez
Central Michigan University
k.p.j@cmich.edu

Currently, there is a shortage of Americans entering STEM careers. Furthermore, women remain underrepresented in these fields. In this paper I discuss the career decisions of three undergraduate women mathematics majors who, during their undergraduate years, expressed an interest in obtaining a career in mathematics but lacked substantial knowledge of potential careers. I explore how these women transitioned from college into the workforce and how their career decisions were based, in part, on aspects of their identities and on environmental opportunities. The implications of this work provide knowledge to the field of how to retain certain individuals in the field of mathematics.

Keywords: Gender, Post-Secondary Education, Affect, Emotion, Beliefs, and Attitudes

Currently, there is a shortage of Americans entering STEM (Science, Technology, Engineering, and Mathematics) careers in the United States (National Academy of Sciences, 2010; Huang & Cohen, 2012). Although there does not appear to be a consistent definition amongst national organizations of what is classified as a STEM career, an unspoken definition appears to be any career that requires the knowledge of a Bachelor's degree in a STEM field (excluding careers in K-12 teaching). The shortage of those entering STEM careers is not necessarily due to a lack of talent, but rather is based on the reality that Americans, for various reasons, simply are not choosing to enter these fields. Furthermore, national statistics demonstrate that women remain underrepresented in mathematics and science fields (BLS, 2011). Given the national need for more individuals to enter these disciplines, the underrepresentation of women in these fields should be of widespread concern.

There are many critical junctions within individuals' lives when they make decisions that influence their future career opportunities. Prior research demonstrates that women choose to leave the STEM career pipeline at disproportional rates at every junction along this trajectory. Girls as early as eighth grade demonstrate less interest in obtaining a future career in mathematics or science than their male peers (Riegle-Crumb, Moore, & Ramos-Wada, 2011). Women are less likely than men to declare a college major in a STEM field and are more likely than men to switch their major away from a STEM field prior to graduation (Seymour & Hewitt, 1997). What is unique to mathematics, however, is that women choose to major in mathematics at the same rate as men (NCES, 2010), but are less likely to enter graduate school in mathematics and are more likely to choose to leave graduate programs in mathematics prior to completing the degree than men (Cleary, Maxwell, and Rose, 2010; Herzig, 2004).

There are a multitude of factors that influence women's decisions to leave the mathematics and science fields. Some of the most common mentioned in the literature are the absence of role models, STEM curricula and pedagogy, women's attitudes and beliefs about the fields, cultural pressure, and a 'chilly climate' (Blickenstaff, 2005). Furthermore, it has been argued that not necessarily the same factors affect all areas of science equally and the factors may differ for science and mathematics careers (Riegle-Crumb, Moore, & Ramos-Wada, 2011). Therefore, it is important to study women in mathematics separately from those in other STEM fields.

In my work, I analyze what factors influence undergraduate women mathematics majors' academic and career decisions. In this paper, my analysis surrounds the career decisions made by women who, during their undergraduate careers, expressed an interest in obtaining a career in mathematics but lacked substantial knowledge of potential careers. This paper discusses how these women transitioned from college into the workforce and highlights the role that aspects of their identities and environmental opportunities played within their career decisions.

These women's experiences and career decisions are worthy of a focused analysis because these individuals desired a career in mathematics and had the proper education to obtain one, but lacked knowledge of potential careers. Learning about what led to their career decisions provides knowledge to the field of how to retain certain individuals in the field of mathematics.

Theoretical Framework

Many scholars have explored social and cultural reasons for the shortage of women in STEM careers (Blickenstaff, 2005; Hanna, 2003; Spelke, 2005; Wallon, 2005). One perspective is that of the "glass ceiling", suggesting that women are not given the same opportunities as men to succeed in the STEM fields through means of discrimination. That is to say that external barriers prevent women from being successful in these fields. Another perspective is that the shortage of women in these fields is a result of choices made by women. In other words, women are making the decision themselves not to pursue STEM careers. This perspective gives agency to women and views them in control of their own life decisions (Damarin, 2000).

In my work, I follow this latter perspective, focusing on the educational and career choices made by women. This perspective does not ignore external barriers or cultural norms. Rather, it views women as having the choice of how to allow these factors to influence their beliefs and decisions.

When considering what influences an individual's choice of career, research demonstrates that the situation is complex. Eccles and her colleagues (2011, 1994) have developed a framework on achievement-related choices that takes into account the role gender plays within these decisions. In this framework, educational and vocational choices are most directly related to the individual's expectations for success in a field and the subjective task value (STV) that they attach to a field. STV is described as having four major components: 1) utility in facilitating one's goals or external rewards, 2) enjoyment, 3) ability to manifest one's identities and core values, and 4) the cost of engaging in the activity (Eccles, 2011).

In this framework, an individual's beliefs are based on a complex interplay of multiple factors, such as cultural norms, personal experiences, input by significant people in their lives, gender-role beliefs, and perceived ability, all of which are affected by one's gender. It is this framework that has informed my analysis of the choices made by the women in my study.

Methods

The study described in this paper is a part of a larger longitudinal study analyzing the experiences and career selection of women mathematics majors. As part of the larger study, I conducted a series of three 90-minute interviews with 12 undergraduate women mathematics majors at two different universities in the Midwestern United States to learn what motivated these women to major in mathematics and to learn about their future career goals. I employed the interview technique known as in-depth, phenomenologically-based interviewing and followed the Three-Interview Series protocol as described by Seidman (1998). The interviews were conducted during the student's junior or senior year of college and generally took place over the span of one month. Then, three to five years after the initial interviews, I conducted a

one-hour follow-up telephone interview with eight of the original 12 participants, to learn what influenced their career decisions since graduating from college. For this paper, I will focus on a subset of three of these participants as described below.

All 12 of the original participants were U.S. citizens, had Caucasian heritage, grew up in the Midwestern United States, and attended college immediately following high school. Of the original 12 participants, half were planning to become middle or high school mathematics teachers. The remaining six participants had consciously made the decision not to have a career in teaching. Of these six, three had specific career goals that they were working towards. The other three participants, however, did not have any specific career plans, in part because they did not know what careers were available to them in the field of mathematics. It is these three participants who are the focus of this paper.

All interviews were audio-recorded and transcribed. The four interviews for each of the participants (three while they were students and one 3-5 years later) were critically analyzed and coded inductively with regards to these women's desired career qualities and what influenced their actual career paths. For each participant, common themes were noted between the participant's first set of interviews and the follow-up interview three to five years later, emphasizing validity within the data. Profiles were then created for each of the participants in order to accurately represent each woman's account (Seidman, 1998). The profiles were then analyzed for common themes arising between the women's experiences.

Findings

The three participants I focus on in this paper have earned bachelor's degrees in mathematics. They all chose this major because they had strong mathematical identities and because they enjoy the field of mathematics (Piatek-Jimenez, 2013). Despite their choice of major, however, while they were undergraduates they were unaware of what careers they could obtain with a degree in mathematics. In fact, all three of them specifically stated that the biggest obstacle to entering a career in mathematics is not knowing what their options are. In this section I provide details of how each participant transitioned into the workforce. In the following section, I analyze the commonalities found amongst these participants' experiences and decisions with regards to Eccles' (2011, 1994) framework.

Kelly

While an undergraduate, Kelly was unaware of potential careers available to her upon graduation with a major in mathematics. People frequently told her that mathematics is a good field to enter because of the many career options available, but when pressed, no one seemed to know what these options were. In an attempt to learn more about potential careers, Kelly spent a day job-shadowing a banker and attended a talk by a mathematician at the National Security Agency, but determined that neither career was a good fit for her.

When considering what qualities she wanted in a career, Kelly mentioned that she did not want a desk job. She considers herself to be a social and active person and wanted a job with human interaction and physical activity. She claimed, "Working at a desk is 'ugh'; I like to get up and move around."

Because of her Spanish minor, Kelly initially planned to study abroad during her senior year of college, however her plans changed when she learned how expensive studying abroad would be. Instead, Kelly opted to graduate a semester early and travel abroad once she graduated:

> Part of the reason why I decided to go abroad was because I wanted to study abroad, but I didn't want to pay all the money to study abroad. So, I thought a good goal was for me to graduate early and then use that extra semester to go abroad for four months or for six

> months... The first country I went was Russia... My purpose was to pick a Spanish speaking country, but I just, Russia sounded like a little bit more fun. So, but then I did end up going to a Spanish speaking country after that... [In] Russia and South Korea I taught English, and then, in the Dominican Republic I worked as an event coordinator at a resort.

Even though Kelly initially planned to live abroad for only four to six months, these short-term plans lasted two and a half years. For each position, Kelly was hired for a fixed amount of time and after each contract expired she would return to the U.S. for approximately one month before leaving again for the next country. “I could have stayed in each of those places, but I just, I wanted a new experience, something different.” When asked if she had considered math-related positions, too, Kelly responded:

> The type of position that I wanted was the short-term position, and the math positions were all relocating there for four or five years, and that was something that I wasn’t willing to do. So, I was just going for the short-term positions.

Most recently, Kelly obtained a job in her home state as a middle school Spanish teacher. Although she had been looking for another job abroad, she had not yet found one that was a good fit for her. She then learned through her father that there was a position opening mid-year for a Spanish teacher in her hometown. Given the need of the school district, they hired her without a teaching credential. Since Kelly did not have another position abroad lined up yet, she decided to take advantage of this opportunity that arose.

Although Kelly had initially determined that she did not want to become a teacher, now that she is in the classroom, she is happy with this decision for the short-term:

> I’m enjoying my job for the most part and everything like that, but I don’t know if that’s something that I could really do for long-term... I’m going to be focusing on teaching at least for the next five, ten, years or so... I’ve just kind of fallen into [teaching] and it seems to be working out well, so yeah, I might as well pursue it a little bit and see what happens.

Although Kelly is currently a middle school Spanish teacher, she has begun an online program to earn a teaching credential in mathematics, with the hope of eventually finding a position teaching mathematics. She explains this decision by saying, “Even though Spanish seems to be where things are taking me now, math has always had a soft spot for me in my heart. I just, I think it’s fantastic!”

Mandy

Despite her decision to major in mathematics, Mandy did not know what she wanted to do once she graduated. Mandy even felt embarrassed when people would ask her what she was going to do with her degree because she would have to tell them that she did not know. She simply knew that she did not want to have a career doing pure mathematics. “I just like applying math to things. I don’t want to do pure math… I want to apply my math skills to something bigger than math. So, to another field [such as] biology maybe.”

Upon graduation, because Mandy did not know what career path to pursue, she decided to go to graduate school. “I think part of it was I didn’t know what my options were for finding a job.” She ended up applying to two very different graduate programs. One of the programs was in applied mathematics while the other was in information communication sciences. Mandy learned about the latter program through a colloquium talk given at her university. In making her decision of which program to attend, Mandy claimed, “It almost came down to a coin flip between [the two programs]. I got assistantships at both of them, but I just felt like I needed a change of pace from math and I wanted something with more communication tied in.” In the end, Mandy decided to do the Master’s program in information communication sciences. Even

though she was not certain whether this program would be a good fit for her, knowing it was only an 11-month program, she figured, “I can do anything for a year.”

Throughout graduate school, the director of the program took it upon himself to mentor Mandy. The same professor also assisted Mandy in obtaining multiple job interviews, one of which lead to her current position. Mandy has found a job as an IT consultant at a consulting company in a large city. The majority of this company’s clients are in the healthcare sector. Mandy described her current work as follows:

> I’m helping with a wireless appointment, and now we are doing one in a new hospital here. So the access points are installed and we walk around with a survey tool tweaking the coverage areas and making sure that the radio frequencies are at the power levels to make sure that it’s at the right level without being too high. So, I really like that cause it’s like a puzzle.

Mandy claims that while she may not be using specific content that she learned as an undergraduate, she is using many of the skills she obtained as a mathematics major, “the problem-solving, the thinking, the analyzing, all those skills I gained learning to write proofs.”

Mandy really enjoys her job because she likes doing “technical” work. She also enjoys that she is out in the field each day. “I *love* that I don’t sit at one desk all day. I like that it changes it up.” The only concern that Mandy has about her current job is that she travels approximately half the time, and if in the future she gets married or has children, Mandy does not want to continue traveling so extensively. She does state, however, that she would still want to have a job in a “technical field.”

Nicole

Like the other participants, Nicole did not know what careers were available to her upon graduation. Her father was a high school mathematics teacher, but Nicole did not want to enter the field of teaching because she desired “a more glamorous job.” She knew, however, that she wanted to stay within the field of mathematics.

During her senior year, Nicole saw an advertisement on Facebook for “Math for America.” Through this program, she would be able to earn a Master’s degree from Columbia University Teacher’s College with all expenses paid and then teach in New York City’s public schools for four years after completing her degree. Despite the fact that Nicole had originally decided not to enter the profession of teaching, given that she was close to graduation and did not know what other options she had, she chose to apply to this program.

At the time, Nicole clearly stated that she did not envision herself remaining as a teacher for a long period of time. She simply saw this as a short-term opportunity and not as something that would lead to a future career. The fact that it was a short-term program specifically appealed to her because she felt it would give her time to discern a long-term career goal.

Upon completing her Masters degree, Nicole learned that the “Math for America” program would continue to pay for her to take a college class each semester for the next four years while she taught in the New York public schools. She decided to take advantage of this opportunity and began a PhD program in mathematics education:

> Because I was getting, like I could get those classes for *free* I kind of thought, “Well, I could do this PhD and that would be cool” I guess. But I mean that’s really kind of; if it hadn’t of been for that, I probably wouldn’t have started it.

Since that time, Nicole has been taking two courses a semester and is currently on track to complete her PhD over the span of four years.

Upon completing her PhD in mathematics education, Nicole is still unsure of what career path she will take. "I don't really know what I can, what I'm going to do with it." One option she is considering is a teaching job at a university, but she clearly states that she would only be interested in a position teaching mathematics, rather than teaching education courses, demonstrating that she still wants a career with an emphasis on mathematics.

Reflecting on her decision to join "Math for America" after college, Nicole says that she does not know if she would make the same decision again:

> I don't know... I wouldn't say that I regret it… I'm not sure if I would be able to do anything differently if I could go back… I don't know that I'm that happy with what I'm doing right now… I guess I'm as unsure as I was three years ago… I kind of think I just really didn't know what I wanted to do. (sighs) That kind of started to get me to change my mind [about teaching].

Nicole admits that while she is not necessarily happy teaching, four years out of college she is no more knowledgeable about careers in mathematics than she was when she graduated. She also clearly states that the reason she chose to go into teaching was because she felt like it was her only option. She does admit though that one thing that was appealing to her about teaching was "I didn't really want to have an office kind of job."

Analysis

Although these three women transitioned into the workforce in very different ways, there are some common themes that permeate their stories. At the time of graduation, all three of these women remained interested in wanting careers in the field of mathematics. Because of their lack of awareness of careers that also fit other desirable job qualities (for example, not wanting a desk job), they chose short-term options instead of focusing on long-term plans. For Kelly and Nicole, their short-term jobs were in fields they knew they did not want to remain in for a long period of time, but that satisfied other short-term goals, such as traveling abroad or earning a Master's degree. These decisions appear to be the results of trying to postpone making long-term career plans. In Mandy's case, initially unsure whether her short-term plans (her Master's program) would lead to a long-term career, she chose an option that could potentially prepare her to have a career in a STEM field.

According to Eccles et al. Model of Achievement Related Choices (Eccles, 2011), the two sets of beliefs that most directly influence an individual's career choice are expectations for success and subjective task values. The first of these, expectations for success, influenced these women's choice of major (Piatek-Jimenez, 2013), but did not appear to influence their career decisions. This might be, in part, because these women were entering short-term careers. Since their jobs were not intended to be long-term, their expectations for success was less influential on their decisions.

On the other hand, the role of subjective task values appeared to be instrumental in their short-term career decisions. In particular, their decisions were based on a synthesis of the components of enjoyment and the ability to manifest one's identities and core values. These three women all identify as "math people", yet they also identify as social and active individuals. Their limited knowledge of mathematical careers, however, prevented them from being able to obtain a career in mathematics that satisfied all three of these aspects of their identity. As a result, they placed their identity of being social and active as a priority, at least for the short term.

Both Kelly and Nicole found jobs that allow them to be both social and active at work, yet they are not content with their current positions. They had both chosen short-term jobs hoping to later learn about mathematical careers that fit their desired career qualities. Despite being three

to four years beyond graduation, they are no closer to being knowledgeable about such careers. Therefore, they are still searching for their desired long-term career.

Mandy, on the other hand, entered a graduate program in information communication sciences, which has allowed her to obtain a career that is active, social, and "technical" in nature. Although she is no longer in a mathematical field, it appears that being in a different STEM field is satisfying this portion of her identity. Mandy is aware, however, that later in life if she gets married, her identity will change and that her current position may not fit the needs of those new aspects of her identity. Therefore, it appears that Mandy has successfully transitioned into the workforce by obtaining a career that satisfies her needs, at least until these needs change.

It is also interesting to note the role that environmental opportunities played in these women's present career paths. Each of these women are currently following a career trajectory that was proposed to them at a time when they were discerning their next educational or vocational decision. Given their limited knowledge of mathematical careers, any opportunity that arose became a consideration, even when this opportunity did not entirely satisfy their desired career qualities. It is also important to note that when these women needed to make concessions, they chose to follow a career path that more closely aligned with gender-role affirming aspects of their identities (Morgan, Isaac, & Sansone, 2001).

Furthermore, all three of these women expressed receiving support from their families in their career decisions; however, they also believed that their parents would have been supportive regardless of their actual career choice. This unwavering support, as well as having the financial means to explore short-term options, may have also influenced these women's career decisions.

Discussion

Previous studies have focused on specific reasons individuals have consciously chosen to leave the field of mathematics or other STEM disciplines (Herzig, 2004; Seymour & Hewitt, 1997). The results of my study suggest that some students leave the field of mathematics not specifically due to the desire to leave, but rather because of a lack of awareness of careers in the field. In order to retain more people in the field of mathematics, this population is important to study. These individuals should be among the easiest to maintain in the field, given their desire for a career in mathematics.

This lack of knowledge of mathematical careers exists amongst both male and female mathematics students (Adhikari et al., 1997; Piatek-Jimenez, 2008). Therefore, this is likely to be a reason that both men and women do not remain in the field of mathematics. Given the need to increase the mathematics workforce in the U.S., a national agenda to inform talented students about mathematics careers may be successful in retaining more students within these fields.

The dispersion of career information may assume a number of different forms. A handful of books have been published to assist students in learning about careers in mathematics (Burnett, 2002; Lambert & DeCotis, 2005; Sterrett, 2002). More one-on-one mentoring of mathematics students by university faculty may be useful. Companies and graduate programs may consider visiting universities to actively recruit potential candidates. Furthermore, mathematics departments might consider synthesizing these ideas by creating a capstone course, whose primary responsibility would be to assist students in the transition into the workforce by utilizing the books listed above and guest speakers to inform students of career options in mathematics.

Simply providing information of such careers may not be sufficient, however, if these careers do not encompass other qualities these individuals desire from a career. Given the role that gender plays on one's subjective task values (Eccles, 2011), men and women generally value different qualities within a career. For example, in general, women tend to have a stronger

preference for careers that involve social interaction, helping others, and flexible schedules (Eccles, 2011; Morgan, Isaac, & Sansone, 2001). Therefore, a variety of career opportunities that encompass these qualities need also be proposed.

Finally, when needing to choose between aspects of their identities, intentionally or not, the women in this study placed gender-role affirming qualities as a higher priority than qualities that challenge their gender-roles. More research needs to be done to learn if this is a wide-spread trend, and whether or not these decisions are also influenced by culture or social class.

STUDENTS WHO SWITCH OUT OF CALCULUS AND THE REASONS THEY LEAVE

Chris Rasmussen
San Diego State University
chris.rasmussen@sdsu.edu

Jessica Ellis
San Diego State University
ellis3@rohan.sdsu.edu

A substantial percentage of college students who enrol in Calculus I intending to take more calculus decide at the end of the semester not to continue with calculus. This represents a huge loss in terms of the need for more students to pursue a major in one of the science, technology, engineering and mathematics (STEM) disciplines. In this report we examine the characteristics of STEM intending students who begin their post secondary studies with Calculus I and either persist or switch out of the calculus sequence, and hence either remain or leave the STEM pipeline. The data used for this analysis comes from a unique, in depth national survey aimed at identifying characteristics of successful programs in college calculus.

Keywords: Post-Secondary Education, Instructional Activities and Practices, Assessment and Evaluation

Introduction

As detailed in the recent report in the USA from the President's Council of Advisors on Science and Technology (PCAST, 2012), there is tremendous need for more students with degrees in science, technology, engineering, and mathematics (STEM). For example, the PCAST report predicts that, over the next decade, approximately 1 million more STEM graduates above and beyond the current level of STEM graduate production will be needed in order to meet the demands of the national workplace. One strategy for meeting this need is to increase the retention of STEM majors. In fact, the PCAST report predicts that simply increasing the retention of STEM majors from 40% to 50% would go a long way to meeting this need.

As reported by Seymour (2006), students leave STEM majors primarily because of poor instruction in their mathematics and science courses, with calculus often cited as a primary reason. Therefore, in order to develop more successful retention strategies, the field is in need of a deeper understanding of what distinguishes those who continue with calculus from those who do not.

The purpose of this report is to examine the characteristics of STEM intending students who begin their post secondary studies with Calculus I and either persist or switch out of the calculus sequence, and hence either remain or leave the STEM pipeline. The data used for this analysis comes from a unique, in depth national survey aimed at identifying characteristics of successful programs in college calculus. In this report we answer the following three research questions: (1) What is the profile of students who choose not to continue with calculus? (2) What are the reasons that students give for switching out of calculus? (3) What characterizes the behavior of switchers and the behavior of their instructors?

Background

Researchers in Higher Education have extensively studied factors related to student retention at the post-secondary level, often focusing on the effects of student engagement and integration on persistence (e.g., Kuh et al., 2008; Tinto, 1975, 2004). According to Tinto's integration framework (1975), persistence occurs when students are socially and academically integrated in the institution. This integration occurs through a negotiation between the students' incoming

social and academic norms and the norms of the department and broader institution. From this perspective, student persistence is viewed as a function of the dynamic relationship between the student and other actors within the institutional environment, including the classroom environment.

Guided in part by this theoretical and empirical work in higher education, this paper reports on a five-year study of Calculus I instruction at colleges and universities in the United States. The first phase was a large-scale national survey of Calculus I instruction at two- and four-year colleges and universities. The survey was restricted to what is known as "mainstream" calculus, the calculus course that is designed to prepare students for the study of engineering or the physical sciences.

The second phase of the study consists of case studies examining Calculus I instruction at seventeen colleges and universities identified as having a notable measure of success with their Calculus I program. Success was defined in terms of both the percentage of students who had successfully completed the course and the percentage of students who maintained or increased their interest in continuing the study of mathematics beyond Calculus I, controlling for the varying academic strengths and interests of the entering students at different institutions.

Methods

The large-scale national survey of mainstream Calculus I instruction was conducted across a stratified random sample of two- and four-year undergraduate colleges and universities during the fall term of 2010. Preparation for the surveys included a literature review leading to a taxonomy of potential dependent and independent variables followed by constructing, pilot testing and refining the survey instruments (Lodico, Spaulding, & Voegtle, 2010; Szafran, 2012).

A total of six on-line surveys were constructed: one for the calculus coordinator; two for the calculus instructors of which one was administered immediately before the start of the course and the other immediately after it ended; and three for the students of which one was administered at the end of the second week of the course, one just before the end of the course, and the last one year later to those students who had volunteered their email addresses. In addition, instructors reported on the distribution of final grades and submitted a copy of the final exam. All surveys were completed online, and no incentives were given for completing the surveys. For the analysis reported here, only the three student surveys were used.

The survey was sent to a stratified random sample of mathematics departments following the selection criteria used by Conference Board of the Mathematical Sciences (CBMS) in their 2005 Study (Lutzer et al, 2007). Following the strategy of CBMS, we separated colleges and universities into four types, characterized by the highest mathematics degree that is offered: Associate's degree, Bachelor's degree, Master's degree, and Doctorate. Within each type of institution, we further divided the strata by the number of enrolled full time equivalent undergraduate students, creating from four to eight substrata. We sampled most heavily at the institutions with the largest enrolments. In all, we selected 521 colleges and universities: 18% of the Associate degree colleges, 13% of the Bachelor's degree colleges, 33% of the Master's degree universities, and 61% of the Doctoral universities. Of these, 222 participated: 64 Associate degree colleges (31% of those asked to participate), 59 Bachelor degree colleges (44%), 26 Master's degree universities (43%), and 73 Doctoral universities (61%).

There were 660 instructors and over 14,000 students who responded to at least one of the surveys. There is complete data (the first five surveys completed and linked with each other) for 3103 students enrolled with 309 instructors at 125 colleges or universities. However, in order to

answer our research questions we did not need to restrict ourselves to the completely linked data set. Instead, we needed either a student end of term survey or follow up survey.

Results

Depending on a student's initial intention to continue with calculus and whether they switched or persisted with their intention, we used multiple questions across surveys to classify students into four categories: Culminaters, Persisters, Switchers, and Converters. Culminaters are those students who began and ended the course not intending to take Calculus II. These students typically only need Calculus I for their major. Persisters were those students who initially intended to take more calculus and did not change this intention. Switchers, on the other hand, were those students that started Calculus I intending to take more calculus, but then by the end of the term (or one year later) changed their plans and opted not to continue with more calculus. Finally, Converters were those students who initially did not intend to take more calculus but by the end of term changed their mind and wanted to continue taking more calculus. Out of a total of 7260 students for which we could code in terms of one of the four categories, there were 1,789 Culminators, 4,710 Persisters, 671 Switchers, and 90 Converters.

Persisters and Switchers constitute the two main categories of STEM intending students. For STEM intending students in our sample, we found that 12.5% of them were classified as Switchers. In order to improve retention of STEM majors, we need to understand how Switchers and Persisters are similar and different. The following analysis focuses on comparing Persisters and Switchers.

To address our first research question, we compared Switchers and Persisters across a number of variables. In this report we provide results from gender, ethnicity, career path, and academic preparation. Data for each of these variables was collected on the start of the term survey.

Of the students who reported gender information, 41.5% (1317) of STEM intending students were female and 48.5% (1856) were male. In comparison to males, the percentage of female Switchers is significantly higher, indicating that women are more likely to leave a STEM major. Specifically, only 11% of 1856 males were identified as Switchers whereas 20% of the 1317 females were Switchers (χ^2 (df = 1, n = 3173) = 49.14, p < .001). Contrary to the observed differences among gender, there were no statistically significant differences by ethnicity (χ^2 (df = 7, n = 3169) = 3.210, p = 0.865).

We also analyzed differences by career path. Switcher rates differed significantly by career choice, with Engineers switching at very low rates (5.9%) and the biological sciences switching at much higher rates than average (24.8%). These results made us interested to know how this was related to differences in gender. As shown in Table 2, the switching behaviors within career choices varied significantly based on gender (χ^2 (df = 15, n = 3141) = 102.9, p < .001). For example, in the biological sciences almost 30% of females switched while only 17% of males did so. Similarly, in the fields of math, physical sciences and computer science women switched out at two to three times the rate of males in the same fields.

Table 1: Relation Between Career Choice and Gender

	Male		Female	
Career Choice	Persister	Switcher	Persister	Switcher
Biological Sciences	82.55%	17.45%	70.35%	29.65%
Life, Earth, and Environ. Sciences	81.33%	18.67%	82.40%	17.60%
Math and Physical Sciences	95.04%	4.96%	85.88%	14.12%
Engineering	94.45%	5.55%	93.11%	6.89%
Computer Science	88.39%	11.61%	77.27%	22.73%
Math or Science Teacher	86.84%	13.16%	82.98%	17.02%

We addressed academic preparation by examining coursework taken in secondary school, Advance Placement (AP) pass rates, SAT scores, self reported algebra skills, and end of term self assessment of preparation. We conjectured that Switchers were less well prepared than Persisters when they began their postsecondary study of Calculus I. In broad terms, this conjecture turned out not to be the case. There was no statistically significant difference between the percentages of Switchers compared to Persisters who took Calculus in high school (χ^2 (df = 1, n = 2676) = 2.12, p = .15). Similarly, the mean SAT score for Switchers (M = 642, SD = 86.97) was not significantly different than that for Persisters (M = 651, SD = 75.823), t(2710)= 2.233, p = .076. It was the case, however, that Persisters had significantly higher mean AP Calculus BC scores (but not AB scores) than Switchers. However, the number of students who took the BC exam and enrolled in Calculus I was relatively small.

To address our second research question (reasons why Switchers are choosing to not continue on in calculus), we looked at Switchers' and Persisters' responses to an end of the term survey question in which students could check off multiple reasons for not continuing with calculus. The most frequently given reason for not taking Calculus II was a changed major, with 38.9% of Switchers selecting this option. Because students were allowed to select multiple responses, we were interested to know the overlap between reasons. Specifically, we were interested in the other reasons Switchers who changed majors gave for not continuing on in calculus. As shown in Table 2, this analysis shows that of the Switchers who replied that they are not taking Calculus II because they changed their major, 31.4% also replied that their experience in Calculus I made them decide not to take Calculus II.

Table 2: Reasons Switchers Give for Not Taking Calculus II

Reason for not taking Calculus II	
My experience in Calculus I made me decide not to take Calculus II	31.4%
To do well in Calculus II, I would need to spend more time and effort than I can afford	28.7%
I have too many other courses I need to complete	27.6%

I do not believe I understand the ideas of Calculus I well enough to take Calculus II	18.8%
My grade in Calculus I was not good enough for me to continue to Calculus II	11.5%
I never Intended to take Calculus II	6.1%

This result is consistent with Seymour's (2006) finding that students frequently leave STEM majors because of their experience in their introductory courses, including Calculus I. This finding necessitates a better understanding about the nature of the Calculus I experience, which leads to our third research question.

For the third research question, we investigated several different variables to understand students' experiences in Calculus I, including student behavior in and out of class and student description of their Calculus I instruction. For example, students were asked to report how frequently they did each of the following activities during class, from never (1) to every class session (5): contributed to class discussions, were lost and unable to follow the lecture or discussion, asked questions, and simply copied whatever was written on the board. For each of these questions, we conducted an independent-samples t-test to compare responses for Switchers and Persisters. As can be seen in Table 3, there was a significant difference in the responses for the amount of time spent contributing to class discussions between Switchers and Persisters, time spent lost and unable to follow the lecture or discussion, and time spent simply copying whatever was written on the board, but there were not significant differences between Switchers and Persisters on time spent asking questions. These results indicate that Switchers report spending less time in class contributing to class discussion, more time lost and copying down what is written on the board, and the same amount of time asking questions as reported by the Persisters. Taking these together, Switchers report being *less engaged* than Persisters during class. This is despite the fact that their mathematical preparation was not significantly different from that of Persisters.

Table 3: Student Reports of in-class Behavior.

During Class:	**Persister**	**Switcher**
I contributed to class discussions.**+	2.69 (1.25)	2.47 (1.17)
I was lost and unable to follow the lecture or discussion.**	1.89 (0.99)	2.18 (1.02)
I simply copied whatever was written on the board.**	2.86 (1.36)	3.26 (1.32)
I asked questions.+	2.38 (1.12)	2.34 (1.07)

Note. * = $p \leq .05$, ** = $p \leq .001$, + indicates that Persister mean greater. Standard Deviations appear in parentheses below means.

In terms of out of class behavior, we found that similar to Persisters, about 70% of Switchers worked at a job for at most five hours per week. Moreover, the vast majority of Switchers spent about the same amount of time studying calculus as did Persisters. Moreover, a statistically significant greater percentage of Switchers reported visiting their instructor's office hours either weekly or monthly (56.2% versus 48.1%) and going to tutoring on a weekly basis (25.6% versus

15.2%) than Persisters. Thus, this data suggests that Switchers are making the effort to be successful. Compared to Persisters, they do not work more on an outside job, they are studying as much or more, and they are seeking academic help more so than Persisters. All of this, together with the reasons that Switchers give for not continuing on with Calculus, suggests that a closer look at what happens in the classroom is warranted.

To examine student reported classroom instruction, we conducted a factor analysis on the questions on the end of the term survey pertaining to instructor pedagogy. The 27 items of the student end of term survey were subjected to principal components analysis (PCA). Prior to performing PCA, the suitability of data for factor analysis was assessed and supported the factorability of the correlation matrix. Principal component analysis revealed the presence of four components with eigenvalues exceeding 1, though inspection of the scree plot revealed a clear break after the second component. The two-component solution explained a total of 46% of the variance, with Component 1 contributing 36% and Component 2 contributing 10%. There was a weak positive correlation between the two factors ($r = 0.250$). The results of the analysis are used to create new variables representing these components, hereafter referred to as "Good Teaching" and "Progressive Teaching."

"Good Teaching" included questions where students rated their instructor on the extent to which he or she listened carefully to their questions and comments, allowed time for them to understand difficult ideas, presented more than one method for solving problems, asked questions to determine if they understood what was being discussed, discussed applications of calculus, encouraged students to seek help during office hours, frequently prepared extra material, gave assignments that were challenging but doable, graded exams fairly, and gave exams that were a good assessment of what was learned. "Progressive Teaching" included questions where students rated their instructor on the extent to which he or she required them to explain their thinking on homework and exams, required students to work together, had students give presentations, held class discussions, put word problems in the homework and on the exams, put questions on the exams unlike those done in class, and returned assignments with helpful feedback and comments.

Based on the frequency distributions, we grouped these two variables into thirds, representing low, medium, and high levels of Good and Progressive Teaching. Table 4 shows how low and high levels of Good Teaching and low and high levels of Progressive Teaching relate to the percentage of students who were Switchers. The percentages in Table 4 should be compared to 14.8%, which is the switching percentage for the sample of students who responded to the instructor pedagogy questions on the end of term survey.

Table 4: Switching Rate for Low and High Levels of Good and Progressive Teaching

	Low Good Teaching	High Good Teaching
Low Progressive Teaching	18.8%	13.6%
High Progressive Teaching	14.0%	8.9%

As shown in Table 4, the type of instruction seems to make a significant in student retention (χ^2 (df = 2, n = 3294) = 10.124, p = .006). "Progressive" teaching, which includes instructional approaches that more actively engages students, is associated with lower switching rates. Indeed, a high level of progressive teaching coupled with high levels of good teaching reduces the switching rate from 18.8% to 8.9%. This finding is consistent with Tinto's integration framework

(1975), which connects persistence to students' social and academic integration; engaging students in class are at once integrating them into the academic community, both socially and academically. These findings indicate that Switchers reported having different classroom experiences than Persisters. Their instructors were less likely to actively engage them (working by themselves or with a classmate on problems, having a whole class discussion, asking students to explain their thinking, etc.), they were less likely to contribute to class discussion, and more frequently found themselves lost in class.

Ellis, Kelton and Rasmussen (2013) conducted a follow up analysis to determine if the above results are due to Switchers and Persisters being in different classes, or instead if these students are in the same class but having different instructional experiences. They found that student reports within a class are on average in agreement with instructor reports. In addition, they found that Switchers reported being less engaged than Persisters within the same classes, even when controlling for gender, major, socioeconomic status, and preparation.

Additional studies that include classroom observations are needed to further study the effect of instructional approach on student retention in a STEM major. Nonetheless, these findings are consistent with prior research summarized in the PCAST report and with the seminal work of Seymour and Hewitt (1997).

Conclusion

Up until now there has been little large-scale data collected on who elects to study Calculus I at a university. Additionally, little is known about the effect of Calculus I on student intention to pursue a career in mathematics, science, or engineering. Even information as basic as the US national success rate and the percentage of students in university Calculus I who successfully complete the course has not been reported. This large-scale national study is making a significant contribution to what we know about Calculus I (for example, see Bressoud, Carlson, Mesa, & Rasmussen, 2013).

Findings from this report illuminate the types of students who are switching out of STEM majors, as well as their experiences in Calculus I. It is clear that many of the students who intended to take Calculus II but did not were hard working and well prepared. When asked why they no longer intended to take Calculus II, Switchers reported not continuing with calculus because they changed their major, citing a negative experience in Calculus I and spending too much time and effort in Calculus I as the second and third most responses. When we look more deeply at their experience in Calculus I, Switchers and Persisters report different experiences. This suggests that instructional variables such as actively engaging students, having students explain their reasoning, etc. may make a difference in retaining STEM majors. While many may have conjectured that such a finding is the case, this is the first large scale, national study in calculus to provide data for this position.

RELATIONAL PROBLEM-BASED LEARNING: ADOLESCENT GIRLS' EXPERIENCES WITH AN INCLUSIVE PEDAGOGY FOR MATHEMATICS

Carmel Schettino
University at Albany-SUNY
carmel.schettino@gmail.com

Although the Gender Achievement Gap is closing in mathematics, the "interest gap" in pursuing STEM fields is not. One recommendation for encouraging young women to continue on in mathematical studies is to find instructional methods that allow them to feel more included in the learning process – fostering attitudes such as self-confidence, empowerment and agency. In this study, the journeys of five adolescent girls who were currently studying secondary mathematics with a pedagogical approach that sought to encourage such attitudes named Relational Problem-Based Learning (RPBL) were explored and analyzed to describe the relationship between the pedagogical approach and the girls' attitudes.

Keywords: Gender, Affect, Emotion, Beliefs, and Attitudes, Instructional Activities and Practices

In recent decades, mathematics educators have been called upon to not only change mathematics education to ensure accessibility for the diverse range of students in our culture but to allow for equitable learning environments, including changes specifically focused on underrepresented and underperforming students in our society due to gender, race/ethnicity, class or socio-economic status (SES) (Leder, 2003;McGraw, Lubienski, & Strutchens, 2006). Correspondingly, others have recognized the importance of alternative instructional methods for marginalized groups in the discipline of mathematics and ways in which they might best be served in the classroom (Gutstein, 2007; Ladson-Billings, 1995; Lubienski, 2007; Spielman, 2008). The overall goal here being to increase the number of total underrepresented students interested in continuing with future mathematical studies and increasing the diversity, both in people and ideas, in the field of mathematics, and STEM (Science, Technology, Engineering and Mathematics) fields in general – creating a better field for America and the future.

It is true that for the past decade, the achievement gap in mathematics education has been closing remarkably. Females have higher grades in math and science courses in secondary schools than males, scores between male and female students on the NAEP exams have grown closer than ever (although males are still slightly higher) and the number of women choosing certain mathematics and science undergraduate majors has increased annually (Hill, Corbett, & St. Rose, 2010). However, it has also become evident that men still outnumber women in STEM fields in graduate degrees and professional work in STEM fields. In their 2010 report, *Why So Few?,* one of the American Association of University Women researchers' conclusions is that girls' achievements and interest in mathematics are "shaped by the environments around them" (Hill, Corbett, & St. Rose, 2010). For girls especially, it seems the mathematics classroom environment has a great influence on their attitudes towards learning and it is greatly affected by the relationships and beliefs that are forged in those classrooms. Ideally, the instructional methods that are used would allow all students, regardless of gender, race/ethnicity or SES, the safe, secure space to build those relationships and beliefs that would make their learning experience optimal. Therefore, it should be a goal of mathematics educators to find instructional approaches that satisfy the relational needs of a diverse group of learners. However, given the

inequities that persist in STEM fields and the problems that exist in retaining women in STEM careers, it remains of crucial importance to examine girls' learning and paths to STEM fields of work and study.

In this qualitative study, I investigated the attitudes of adolescent girls who experienced one such instructional approach designed to satisfy these relational needs of many types of learners. Based on a fundamental theory of interhuman connection of learning, a problem-based learning classroom at the secondary level was found in which one sub-population of underrepresented students (adolescent girls) experienced mathematics in an alternate learning environment. Specifically, I desired to explore the five attitudes of enjoyment, self-confidence, value, empowerment and agency towards learning mathematics and the mathematics classroom. I addressed the following research question:

> What is the nature of the relationship between girls' attitudes towards mathematics and their learning of mathematics during and after experiencing it in an Relational Problem-Based Learning (RPBL) environment? How do they describe their experiences?

Theoretical Framework

To situate this study, and hence my own framework for mathematics education, I must put forth the following two premises as stated by Burton (2002):

- Learning in the mathematics classroom is social, not individual
- Coming to know mathematics depends upon active participation in the enterprises so valued in that community of mathematics practice that they are accepted within that community

Within this view, mathematics knowledge is understood to be constructed within the classroom community in which it exists and a learner "knows" mathematics based on the values that are prescribed within that community. Further, and in contrast to a more traditional view of learning mathematics, I situate mathematical learning, and learning in general, within the context of the greater relational approach to knowing – where "knowers are social beings-in-relation-to-others", and these relationships must be built on respect and care, not oppression and power (Thayer-Bacon, 2004). According to this view, education has a relational character and it is just that relationship between the teacher and the student, and even possibly the student and her classmates, that affords the community the opportunity for the interaction in education (Biesta, 2004). The task then is to craft a pedagogical framework for mathematics instruction that facilitates relational learning and construction of knowledge and it should incorporate the ideologies that enable as many students as possible the freedom to create those connections and relationships.

A Pedagogy of Feminist Relation

My theoretical framework , which includes relational trust (Bryk & Schneider, 2003; Raider-Roth, 2005), relational authority (Bingham, 2004), relational equity (Boaler,2008), voice and agency (Taylor & Robinson, 2009), has at its roots what was historically known as Feminist Mathematics Pedagogy, stemming from the gender difference movement of the '90's (Becker, 1995; Boaler, 1997; Burton, 1995; Solar, 1995; Willis, 1996). The intersections and overlaps of these constructs are not coincidental and therefore, I cannot ignore the feminist influence which initiated the concept of valuing learning from a humanistic standpoint and appreciating

individual differences and voices within the mathematics classroom. Solar (1995) posited an inclusive pedagogy based on a postmodern epistemology and identified concrete attributes that characterized the "four dialectical aspects" of feminist pedagogy : (a) passivity and active participation, (b) silence and speech, (c) omission and inclusion, and (d) powerlessness and empowerment. The framework is also corroborated by another model of a feminist mathematics classroom (Anderson, 2005) in which empowerment, agency, development of authority, valuing of intuition, and honoring of voices were key components. The characteristics described in both of these models are consistent with the main tenets of postmodern feminist epistemology that resists dichotomous thinking and focuses on subjective thought and multiple perspectives (Hesse-Biber & Leavy, 2007). Further, it is well known that most traditional pedagogies in mathematics include process-driven and rather objective perspectives of mathematics which create "environments in which most students surrender agency in order to follow predetermined routines" (Boaler & Greeno, 2000).

However, it is important to point out the focus on the humanistic and inclusive aspect of the feminist pedagogy and not the dichotomous "feminine" view on learning. At one point in educational theory this concept of "connectedness" was specifically formalized to support women's and girls' ways of knowing and learning, and specifically in mathematics education (Becker, 1995; Belenky, Clinchy, Goldberger, & Tarule, 1986). However, more recently opponents of gender difference theory in mathematics education promote an "unfixing" of the differences "to see mathematics as an opportunity to develop relations with others and re-make themselves" (Mendick, 2005b). Mendick goes on to say that

> By aligning separate-ness with masculinity and connected-ness with femininity, these approaches feed the oppositional binary patterning of our thinking and in the final analysis reiterate it (p 163).

Supporters of this more humanizing approach to the multiplicities of student relationships with mathematics agree that rethinking gender differences in a larger framework would benefit both boys and girls. It may be possible to do this if mathematical learning were viewed in less of an oppositional way (male vs. female, objective vs. subjective, etc.) and in more of a interhuman relational way – appreciating all of the various needs of connection including being "authentic" and "feeling seen" by the other (Raider-Roth, 2005). So although this framework has its roots in and draws support from Feminist Mathematics Pedagogy based on "women's ways of knowing" it is in not fully dependent on or continually presumptive of it.

Recent interest in fostering mathematical practice standards of perseverance and reasoning through problems has motivated many teachers to investigate the instructional method often referred to as Problem- or Project-Based Learning (PBL). Originating almost thirty years ago in medical schools, PBL has made its way into secondary school classrooms because of its ability to engage students in the multi-disciplinary skills that are needed; including communication, collaboration, reasoning & sense-making (Savery, 2006). In secondary mathematics, little research has been done to date regarding the development of the use of this pedagogy, however implementing PBL in the high school classroom can have many mathematical advantages for learners (Schettino, 2011/2012). The discourse and opportunities for open-ended questioning are just some of the many characteristics of this pedagogy that has many intersections with the feminist and relational pedagogies described above.

Methods

For the purpose of this study, I have defined RPBL as an approach to curriculum and pedagogy where student learning and content material are (co)-constructed by students and teachers through mostly contextually-based problems in a discussion-based classroom where student voice, experience, and prior knowledge are valued in a non-hierarchical environment utilizing a relational pedagogy. A narrative inquiry methodology was chosen for consistency with the theoretical framework and for a relational way of viewing the student's learning experience in both a personal and social way. Because of my intense and intimate relationship with the school, students that were potential participants and the teachers in the study, it was important for me to be as transparent as possible in my research methods and to triangulate the data. I had been involved with the curriculum writing of the PBL materials, training of the teachers and instruction at the school in which the study was being conducted. To maximize validity, I constructed methods of data collection that covered many different perspectives of the student experience. The five young female participants in the study diversely represented the population of girls that were registered in the course that year ranging in age from 14-17. Figure 1 below shows the overall plan of data collection over a six month period for all participants who were adolescent girls in the second term of a year-long integrated algebra and geometry course at Greystone Academy – an independent, single-sex boarding and day school in the northeast United States.

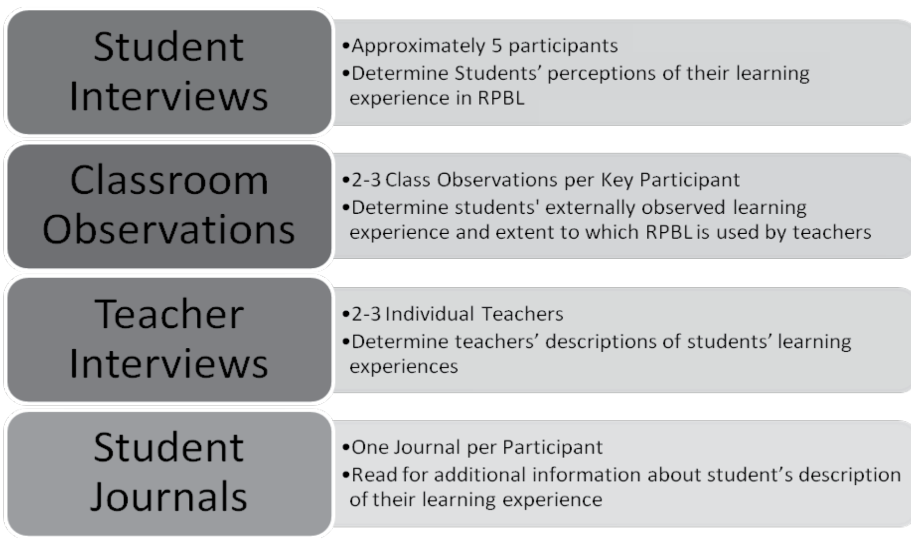

Figure 1: Summary of Purposes of Collected Data

Data Analysis: The Listening Guide

In keeping with the theoretical framework of education as a relational phenomena, I used the Listening Guide (Brown & Gilligan, 1991, 1992; Gilligan, Spencer, Weinberg, & Bertsch, 2003), a voice-centered, relational approach to narrative data analysis. With this method, a researcher employs multiple readings – or "listenings" - of interview transcripts, in each reading a different perspective of the participant's voice is identified and "listened for" (Doucet & Mauthner, 2008) because one's discourse has multiple layers. "I-Poem"s are "written" from first and second-person pronoun phrases from interview transcripts. One researcher stated that the "I-Poem" attends to an associative stream of consciousness carried by the first person voice running through a narrative, rather than being contained by the full structure of sentences" (Kiegelmann, 2009, p.77). In other words, the I-Poem allows you to see a secondary structure to the story that

is brought out by focusing on only the pronouns and how the participants is describing her experience through those voices alone. After creating and coding the I-Poems, they would start showing patterns of alternating voices, but in the third or fourth listenings, you could actually *hear* the voices in tension with each other. The themes of these poems and the poems themselves were member-checked with the participants for accuracy and meaning.

Results and Discussion

Listening to the stories of these five girls, speaking with their teachers (of whom I was one) and reading through their journals allowed me to get an intimate and full portrait of their complex experience not only within the classroom, but of their relationship with mathematics presently but from their past as well. Each girl had different experiences from their past, but it was clear, and probably not surprising, that those past experiences had ramifications on their attitudes at the present. Table 1 shows a summary of the students' varied characteristics and interests in mathematics, as well as their abilities.

Table 1: Student Participant Information

The Listening Guide allowed me to code each of the pieces of data for different aspects of their stories. Their I-Poems gave descriptions with their voices both from the first and second person standpoint giving perspectives on the five attitudes that helped complete the pictures that the plot listening outlined. Although in different ways, each girl attributed some positive change in their attitudes towards learning mathematics to some characteristic of the pedagogy of the RPBL environment.

For example, Sarah, Leona and Alanna had all had prior experiences where they had not been asked to inquire in mathematics. However, when exposed to that type of thinking, they did enjoy it, especially in a relational way. Leona's innate talents of communication and debate made her a natural for discussion and when she realized she could apply this to mathematics class, it became much more fun and comfortable. Once Sarah was encouraged to follow her natural sense of inquiry and extension questions, she enjoyed being valued for those skills. Alanna needed to know that her high intelligence was of use in a problem-based classroom by allowing her independence to work for the class instead of being a distraction in a direct-instruction classroom.

With respect to confidence, the only girl in the study who was of high mathematical ability was Alanna and she claimed to have strong self-confidence ("I was never not confident"), but

would also claim inconsistently her fear of some types of mathematics. So even in a girl with high ability, there was some residual feeling of uncertainty or cultural norm that she wasn't supposed to feel secure in her skills in mathematics. The other girls grew in their concept of self-confidence throughout the year to different places, but their sense of strength seemed to stem from their experiences relating to their peers in the classroom. The more the internal process of learning was made external by discussion, problem presentations, verbal questioning and answering by students, the more they were able to "see" that process unfolding and being constructed and feel more confidence that everyone was on the same page, or least that it was out in the open. Kacey's confidence, which was such an integral part of who she is, allowed her to make the most of the relational aspect of this course. She questioned freely, conjectured regularly and took risks openly in almost every class. It was extremely natural for her and she showed others how to "do mathematics" in many ways.

The girls' sense of empowerment seemed to change by viewing mathematics through a lens of multiple perspectives, valued inquiry and connection to prior knowledge. All girls expressed appreciation for the opportunities to look at problems from multiple solution methods that originated with student presentations. One of Alanna's I-Poems moved from the second person disassociative "you" voice towards the first person, showing more ownership for her learning in the class.

more opportunity for you to affect your own learning
you get another idea
you just do it
you see something
you notice things for yourself

I like to see it
I notice things for myself
I have a better grasp
I'm just learning
I'm just that person
I think
I think I'm that independent
I want to learn it for myself

Agency was viewed differently by many of the girls depending on how much agency they had come to this RPBL class with initially. All of the girls' views of the five attitudes that were triangulated with their teachers' comments, my classroom observations and their journal writings are summarized in table 2.

The RPBL Framework

From the stories these girls told I could draw conclusions about certain aspects of the RPBL that connected to each of their attitudes, as they mentioned them over and over. The tenets of RPBL pedagogy that coincided most often with the codings from the girls' stories were: 1) Connected Curriculum 2) Justification not Prescription 3) Ownership of Knowledge Production and 4) Shared Authority. It is imperative that the curriculum used be based on scaffolded problems that are decompartmentalized such that students can appreciate the connected nature of the mathematics they are learning. The instructor also needs to set a culture of a natural focus on "why" in solutions and foster inquiry with interesting questions that value curiosity and assess creativity. The whole classroom community and structure needs to encourage individual and

group ownership by the use of journals, student presentations, extension questions, teacher wait time, and other discourse moves. The purposeful dissolution of any authoritarian hierarchy with deliberate discourse moves to improve equity and send the message of valuing risk-taking and all ideas will created a sense of shared authority.

Table 2: Cross-Student Comparison of Five Attitudes in Learning

Student	*Relationship with Enjoyment*	*Concept of Self-Confidence*	*Vision of Value*	*Realization of Empowerment*	*Journey towards Agency*
Sarah	With support and praise, surprisingly enjoyable when allowed to follow her own inquiry	Still developing, mending the damage of comparison, competition and silence	Math is more of a tool for science, but problem solving is a life skill that is valuable	Realized strong voice of inquiry for extension questions, leadership skills and ability to take risks	Still dependent on teacher for validation, but strong increase in independence and interdependence in directing learning
Leona	Enjoyment comes from deeper understanding, reasoning – knowing the "why" and communicating	Improvement because the class played on her strengths of communication and relational skills	Math is 'something you must do', but the problem solving skills help in other disciplines	Strong newfound sense of her own voice in the classroom, but grappling with her power in her learning	Relational nature helped bring out her own agency in learning, appreciated multiple perspectives immensely
Isabelle	Views problem solving as fun, like doing a puzzle, enjoys relating others by helping and being helped	Sense of confidence not necessarily related to mathematics, but gave her an advantage in discussion and risk-taking	Sees the relevance of big picture problem solving or calculation skills, but does not see its necessity	Realized the possibility of the subjective nature of mathematics and how voicing her own ideas and/or listening to others added to the learning experience	Students can be more agentic because their understanding is "out in the open" - no one "keeping up appearances of understanding since they are constantly questioning
Alanna	Pride, satisfaction and fulfillment from accomplishing learning independently, in her way and above her expectations	Confidence in her ability remained constant, but concept of self as a student changed drastically (see empowerment and agency)	Mathematics is a worthwhile subject to study, but the class was always boring until RPBL	Being an independent learner doesn't mean working alone, it means collaborating with your peers and building knowledge together.	Seeing things with "her own eyes" is more meaningful than "being told" by a teacher, found appreciation for agency in her learning
Kacey	Enjoyment flourished even though her achievement did not	Initial strength did not wane and allowed for risk-taking and sustained inquiry	Mathematics value is in its "beauty" not necessarily in its everyday usefulness or applications	Grows from a individual and group sense of ownership of knowledge that is co-constructed, stems from connections made through the problems	Juggled balance between independence and interdependence in her learning – but the agency and direction in learning came from her and her peers.

Implications for Future Research

Because of the positive nature of the experiences of these girls in relation to mathematics and the mathematics classroom, it would be wise to do a larger scale study on these attitudes with respect to RPBL pre- and post- classroom intervention. Clearly, no intent of generalizability is implied from the narrative inquiry, only obtaining a rich description of their experiences in the hope of understanding it and their perspective of it better. However, should further research find that RPBL is an effective means by which girls' attitudes towards learning mathematics can be improved a great deal of professional development will be needed for teachers as well as curriculum work and support. All of which will need to be assessed for effectiveness and delivery within the classroom potentially for underrepresented groups of all students.

PARENT PERCEPTIONS OF MATHEMATICS LEARNING AT HOME AND IN SCHOOL

Margot Ely

Parents of forty-nine elementary school students who attend an alternative urban after school mathematics program speak out about impediments of and supports to the productive teaching of mathematics and their suggestions for what is needed to help promote such teaching at home and school. This qualitative research study acknowledges parent voices in finding a common ground to negotiate potential conflicts and areas of dissonance and agreement in order to further the dialogue about creating meaningful mathematics teaching and learning for urban children.

Keywords: Affect, Emotion, Beliefs, and Attitudes, Elementary School Education, Equity and Diversity, Instructional Activities and Practices

Purposes of the Study

Parents can make valuable contributions to the discussion of improving mathematics teaching and learning. In 2011-2013 this stance led us to document our participant parent's beliefs, attitudes and suggestions about meaningful math learning at home and in school. Those data, then, form the basis of the present paper.

Theoretical Framework

The literature stresses that parents' involvement and their beliefs about mathematics relate directly to how children learn mathematics in school [Eccles, 1993]. Examining home and school contexts and parent perspectives is seen as crucial for improving mathematics learning of students whose access and engagement is limited [Allexsaht-Snider & Hart, 2001]. Schools with high levels of parental and community involvement report increased student learning, attendance and self-directed behavior [National Institute on Out-of-School Time, 2000]. Family involvement in schools is therefore central to providing high quality education for all students. However, most parent involvement initiatives assert school values over those of parents [Civil, 2001; Tate, 2005, 2007]. The results of this study support that stance.

The In Addition After School Mathematics Project is situated in a public elementary school of a major metropolitan community. In 2011/13, we served forty-nine students in grades 3, 4, and 5 and their parents. The families are of low socio-economic status. Our definition of "parent" includes any prime caregiver such as grandmother or uncle. The In Addition students are always selected by random lottery. The sole criterion for acceptance rests on a commitment for children to attend two hours a day, three days a week, from September to May. Parents and their children attend two weekend retreats, one in October and one in May. We meet with parents once a month for math workshops at the children's school. The multiethnic group of children and their parents are of African American, Latino, Chinese, and European heritage. The first language of many parents is other than English. We provide translation services where needed.

Modes of Inquiry

This narrative research study analyzed written, interview, videotaped, and focus group data provided by parents and surrogate parents of the urban after school mathematics program. In this paper we maintain anonymity of people and places as part of trustworthiness in keeping our promises to them. Further, we use the term "parents" to subsume all primary caregiver adults who provided data. We sought to amalgamate what parents reported are impediments of and supports to productive teaching of mathematics, as well as suggestions for what is needed to promote such teaching at home and school.

Data for this study were collected via open-ended questionnaires, focus group sessions, field logs, and video-taped segments of In Addition classroom events. Audio taped focus group sessions and questionnaires centered about two questions: "What helps the learning of math at home? in School?" and "What hinders the learning of math at home? in School?"

Audio and video-taped sessions were transcribed. Questionnaire results were categorized. Transcripts were coded in a qualitative, analytical process [Wolcott, 1990] by studying the text, chunking it into meaningful categories and re-categorizing into over-arching themes.

Each of three members of the research team analyzed independently. The group met to compare, contrast and discuss emergent categories and insights as well as discrepancies. This resulted in overall agreement.

Results

Following is a selection of themes resulting from our analysis that seem particularly pertinent to this presentation. They strongly emphasize that:

1. At home it is best to teach children in the same way as teachers do in school.
2. We as parents must act as substitute teachers because there isn't enough time in school.
3. We feel pressure to know the math being taught and how to teach it.
4. What helps the learning of math at home is to apply the math to real life situations.
5. We try to use similar math learning strategies that worked for us in the In Addition parent workshops.
6. To us, teachers and teaching are seen as making the difference in how children learn math.
7. What harms math learning at home is homework and lack of supportive time, space, and materials.

Discussion

Parents voiced that they accepted the tasks of parents-as teachers as their responsibilities; tasks that most probably were defined by school personnel to them and to their children. It seems reasonable to assume that school personnel saw the "parents–as-teachers" function perfectly acceptable and necessary. Because of our experience in other schools and school districts as well as the literature [Cobb, 2002; Herrold & O'Donnell, 2008] we are of the mind that this transfer of responsibility may happen with great force in many schools and with many families in many places.

If this is a trend, then the implications are obvious: math in school is seen by many as a matter of making the way through the math textbook. If there is not sufficient production and or time in school, then math is a matter to be taken care of at home by the children and their parents. The message to parents would be that they need no special math skills or pedagogical talents to complete the work other than those they possess already. This conclusion is bolstered by our data wherein parents described that they receive no or limited direction and materials such as textbooks for use at home.

The pathos inherent in these findings is that our parents buy into them. And why shouldn't they? Most probably this pattern has been true as well for their education. In addition, they are not often invited to interact with school personnel to learn what math to teach and how to do that.

We believe parents can bridge the educational experiences of school and home and see it as imperative to incorporate parents' unique understandings into the ongoing dialogues about reform. Research also indicates that in order to enhance the educational experience of "disadvantaged" students and increase access, equity, and engagement for all students inclusion of parents in the education of their children is essential [Moles, 1993; US Department of Education, 1997]. However, our parent data results, 1, 2, and 3 (see above) are in agreement with the findings of [Eccles 1993]. In order for math reform efforts to move forward, much more attention must be paid to helping parents shift to a more problem solving vision of teaching and learning mathematics.

Our After School Math Project is based on a philosophy of how children best learn, honed over decades of professional involvement by the project founder, as original developer, and continuously shaped and reshaped by all the team members. Our philosophy echoes the recommendations of the National Research Council [National Research Council, 1989; National Research Council 2001], the National Institute on Out-of-School Time [National Institute on Out-of-School Time, 2000] and the National Council of Teachers of Mathematics [National Council of Teachers of Mathematics, 2000]. These leading organizations emphasize that it is essential to provide children with opportunities to be active participants in the development of their own mathematical understandings and to be instructed by teachers using strategies that begin with children rather than with themselves.

Our work with parents is guided by this philosophy. Our parents enter into In Addition activities with enthusiasm, interest, and deepened insights. Yet there is an irony in what we learned. With all of our efforts to work closely with parents about meaningful teaching and learning of mathematics, with all of their voiced understandings and joy, our study results; 1, 2, and 3, attest that the "old school" vision prevails when parents talk of how best to teach children at home. This seems quite reasonable. These parents deeply want their children to succeed, to "make it." And they have read their schools correctly. If teachers assign particular homework, these parents believe that it is their responsibility to take on the role of teacher no matter what is asked.

We are heartened by study results 4, 5, 6, and 7 which indicate that parents see the value of some broader, more child-centered views of mathematics teaching and learning. This illustrates the conundrum.

ONE HIGH SCHOOL STUDENT'S DEVELOPMENT OF MATHEMATICAL DISCOURSE ON TRANSLATION

Elçin Emre	Beste Güçler	Ziya Argün
Gazi University	University of Massacuhetts Dartmouth	Gazi University
elcinemre@gazi.edu.tr	bgucler@umassd.edu	ziya@gazi.edu.tr

The aim of this study is to explore one Turkish high school student's learning of the geometric concept of translation using a communicational approach. Our approach formulates learning as occurring through the changes in students' discourses as they interact with mathematical concepts. Our results confirm that the student's learning about translation was closely related to the changes in particular elements of his discourse. We conclude that the framework we used provides rich tools with which to examine stages of learning as well as the elements of discourse that play important roles in mathematical learning.

Keywords: High School Education, Learning Trajectories (or Progressions), Geometry and Geometrical and Spatial Thinking

Introduction

Transformation is one of the significant concepts in learning of geometry that allows students to develop broad concepts like congruence and similarity (Jones, 2002). There are many studies that focus on students' learning on transformational geometry from cognitive perspectives (e.g., Clements, Battista, & Sarama, 2001; Hollebrands, 2003). However, few studies have explored the issue through a socio-cultural approach. This study explores one Turkish high school student's learning of the geometric concept of translation using a communicational approach to cognition, which considers learning as the process of change in students' discourse (Sfard, 2001). This study is part of a larger research that explores students' development of discourse on transformational geometry. For space reasons, we only consider the concept of translation here and we address the following questions: How does a (10^{th} grade) student's discourse on the concept of translation develop? More specifically, how do the elements in his discourse change as he continues to participate in the discourse on translations?

Theoretical Background

In this paper, we use Sfard's (2008) communicational approach as a theoretical framework. According to this lens, thinking is a special form of communication and the individual who is thinking is considered to be self-communicating. Sfard (2008) explains communication as a dialogical endeavor; it can be intra-personal or interpersonal. Learning is about changing the ways we think and how we communicate what we think (Sfard, 2001). Learning here is conceptualized as change in one's discourse and students' thinking can be examined through their discourses (Sfard, 2001). According to Sfard (2008), discourse is a "special type of communication made distinct by its repertoire of admissible actions and the way these actions are paired with re-actions" (p.297). If the content of a discourse is mathematical, Sfard (2008) describes it as a mathematical discourse.

There are four elements of mathematical discourse: word use, routines, visual mediators and narratives (Sfard, 2008). *Word use* is one of the distinctive characteristics of discourse, the vocabulary that learners use. There are four phases in the development of word use: first one is *passive use*, where the learner is "not able use a [mathematical] word in her own speech" (Sfard,

2008, p.181). The other is *routine-driven use*. In this phase, a mathematical word is uttered to signify the learner's actions on the mathematical object. In *phrase-driven use*, "words become linked to constant phrases rather than with the whole routines" (Sfard, 2008, p.181). Last phase is *object-driven use*, where words signify mathematical objects. *Routines* are repetitive patterns in the actions of learners that are characteristic of the discourse. *Visual mediators* are visible objects that are operated through the communication process, like symbols, graphs, drawings, tables. *Narrative* is any sequence of any utterances indicating the relationships among mathematical objects.

The purpose of this study is to investigate one high school student's development of the concept of translation by using the four elements in his discourse.

Methodology

The study was conducted with one 10th grade student named Okan (a pseudonym) in a medium-sized, urban high school in Turkey. The data for this work was collected through three task-based interviews across six weeks to explore Okan's development of mathematical discourse particular to the geometric concept of translation. Okan was selected as a participant because he was observed in the classroom as an uninterested student but occasionally gave interesting answers to the teacher's questions. Although his grades were low in geometry, the informal interviews with the teacher suggested that his geometrical learning was enhanced throughout the discussions in the classroom. The researchers prepared three different task-based interviews about translations. Each interview lasted about 20 minutes and was video-taped. First interview was conducted before the teacher introduced the topic of translation in the class. Second interview was right after the translation class. The third one was conducted 25 days after the second interview.

Each interview consisted of four types of tasks on the concept of translation. Across the three interviews, each type of task was equivalent to those of the same type in terms of the nature of the translation problem presented and the skills the student needed to use when solving the problem. To ensure equivalence and the validity (Patton, 2001) of the tasks, five experts reviewed the tasks in terms of their parallelism and content. The interviews were conducted in Okan's native language and then translated from Turkish into English by the authors. Data were analyzed in terms of word use, visual mediators, routines and narratives (Sfard, 2008).

Results

We analyzed word use considering the context of the discourse in a qualitative way rather than a quantitative way. Throughout the interviews, passive word use about translation was not observed in Okan's discourse.

Interview I

During this interview, Okan's word use was mainly routine-driven. For example, when we asked him what it means to translate an object, he said that it "is the process of positioning the object from one location to another." In terms of visual mediators, Okan's focus was on the vectors and how he can split them into their corresponding *x* and *y*-components. However, his use of these mediators was not consistent. In fact, during the first interview, Okan had no consistent routine with which he translated mathematical objects. He used some strategies for the problems in a haphazard rather than repetitive way. Therefore we could not identify any routines in his discourse at this stage. Okan was also confused about which narrative to endorse regarding translation. Results indicate that, before the teacher introduced translation, Okan considered

translation as the process of repositioning the location of an object but did not have robust understanding of the concept.

Interview II

The second interview was conducted after the teacher introduced the topic of translation. In this interview Okan's word use was predominantly phrase-driven. For example, when we asked him what translation is, he said "translation is when the objects are moved towards particular directions within the coordinate system". There were also some object-driven utterances in his discourse. For example, he said that "Translation is a transformation that enables the placement of objects within the coordinate system".

There were four kinds of routines (three geometric and one algebraic) determined in Okan's second interview. Every time Okan translated a geometric shape and gave examples for translation, he used these two geometric routines (GR1 and GR2): GR1. Translating one vertice of a given geometric object along the components of the vectors visually and then using the property of translation (it preserves size and orientation) to draw the rest of the translated object. GR2. Translating each vertice of a given geometric object along the direction of the vector and carrying the vertices to its translated location and then connecting the vertices of the translated shape using the property of translation.

After Okan translated objects using GR1and GR2, the researchers asked Okan to find the coordinates of each translated vertice. Okan's responses to these questions elicited one geometric (GR3) and one algebraic (AR1) routine: GR3. Finding the coordinates of the vertices visually using the grids provided in the questions. AR1. After using GR3, Okan regularly wanted to double-check his answer algebraically by adding the coordinates of each vertice of the original shape with the corresponding coordinates of the vector.

Vectors were the primary visual mediators in Okan's discourse during the second interview. He considered vectors as objects that move the geometric shapes as indicated by one of his geometric routines (GR2). He also used vectors algebraically, treating them as ordered pairs as indicated by his algebraic routine (AR1). One of the endorsed narratives that Okan used in his words, routines and visual mediators was: "Translation is the placement of objects in the coordinate system".

When we compare Okan's discourse in this interview with his first interview, we see the following changes in the elements of his discourse: (a) His mainly routine-driven word use changed to being mainly phrase-driven, and (b) his haphazard solution strategies changed to consistent routines in his discourse. He became close to objectifying translation as a form of transformation that preserves the size and orientation of any given geometric object.

Interview III

The third interview was conducted 25 days after the second interview. In this interview, Okan's word use was mainly object-driven. When talking about translation, Okan frequently referred to the translated geometric objects as the end states of the translation process. There were also some phrase-driven utterances in his discourse. For example, while Okan was translating a geometric object, he said "When an object is translated, area, circumference, and the distance between the points [of the original shape] do not change".

In this interview, we identified one geometric routine in Okan's discourse. He used this routine in three of the tasks on which he worked. Throughout the tasks, his approach was generally based on geometric rather than algebraic routines. His geometric routine was GR1. In terms of visual mediators, Okan mainly operated with vectors geometrically rather than algebraically as indicated by his routine GR1. One of the most frequently endorsed narratives in

Okan's discourse was: "If the object is translated...the distances between the points [vertices of the original geometric object] do not change."

When we compare Okan's discourse in this interview with his second interview, we explored the following changes in the elements of his discourse: (a) His mainly phrase-driven word use changed to being mainly object-driven, (b) his four different types of routines (GR1, GR2, GR3 and AR1) were reduced and stabilized to one geometric routine (GR1), and (c) his phrase and object-driven utterances consistently treated translation as an object long after Okan's second interview. Accordingly, his endorsed narratives started resembling actual mathematical facts rather than idiosyncratic utterances he endorsed at the very beginning of his learning process.

Conclusion and Discussion

In this study, we explored Okan's learning of the geometric concept of translation, which was conceptualized as the change in his discourse (Sfard, 2008). Note that this framework does not only focus on students' use of language but also takes into account other elements in their discourse such as their actions and visual mediators. Our analysis of Okan's discourse revealed that these elements of discourse are in close relationship with each other as he shifted his routine-based discourse to an object-based one in the context of translations. The learning trajectory Okan went through in the course of the interviews resulted in changes in each element of discourse, indicating that students need to command all the elements of mathematical discourse in order to enhance their thinking (Güçler, 2013).

One critical aspect of mathematical learning is to change the talk about processes of mathematics to the objects of mathematics (Sfard, 2008). Okan's discourse reflected such development as his routine-driven word use gave way to phrase- and object-driven word use. For the concept of translation, this means a shift from considering translation as actions formed on geometrical objects to considering translation as a distinct mathematical object that belongs to a class of other mathematical concepts (i.e., transformations). A detailed analysis of student discourse helps identify the characteristics of students' trajectories and discourse regarding these important conceptual shifts in transformational geometry.

In this study, we examine engineering students' engagement with the common Student-Professor type problems using a web-based tool designed to develop a conceptual understanding of formulating valid mathematical models. We analyze one student's thinking on five tasks with this tool. Findings suggest that interacting dynamically with verbal, visual, symbolic, and numeric representational spaces of such problems allowed the student to better understand the relationship between coefficients and variables.

Keywords: Algebra and Algebraic Thinking, Modeling, Technology

Background

Consider the well-known problem: Write an equation to represent the following statement: 'There are six times as many students as professors at this university.' Many studies have examined the "student-professor problem" and issues surrounding it (see e.g., Clement, 1982; Cohen & Kanim, 2005). In spite of its seeming simplicity, this problem and its variations (henceforth called SP-type problems) have caused difficulty for students at all levels. The most common error is the *reversal error*; writing $P = 6S$ instead of $S = 6P$. This error has been studied repeatedly, yet its complexity continues to intrigue researchers (Cohen & Kanim, 2005). We have encountered this error while working with college engineering students. In this paper, we focus on the research question: in what ways can an interactive visualization tool help college students analyze and makes sense an SP-type problem? Because of the long history of student difficulties with SP-type problems, we believe this is a useful place to focus our attention.

Many researchers have attributed difficulty with SP-type problems to a "direct-translation" approach (Clement, 1982; Fisher, Borchert, & Bassok, 2010). With this strategy, one makes the sequence of algebraic symbols match the sequence of objects in a word problem. For example, given "There are six times as many students as professors," the reversal error is made by translating directly to 6 times S equals P. MacGregor and Stacey (1993), however, found that when phrasing questions so that a direct translation produces a correct response, students still tended to make the error. They attribute difficulties to an underlying cognitive model of mathematical relationships in which models are based on comparison rather than equality. Others have identified this phenomenon as using a "static comparison" strategy (Clement, 1982; Cohen & Kanim, 2005), where "$6S$ " and "P " are treated as six students and one professor respectively (instead of as the number of students and professors). The equal sign is seen here as representing correspondence rather than equality (Cohen & Kanim, 2005; Palm, 2008).

Two distinct behaviors have been seen in students who successfully solve simple word problems: An *operative approach* involves the use of a hypothetical operation that produces an equivalence relation (Palm, 2008). Fisher et al. (2010) found that writing a non-standard relationship by developing such equivalence relationships decreased the appearance of the reversal error significantly. The second pattern is what Clement (1982) called the *substitution pattern*, where students substitute numbers into the equation's variables and then engage in the operative approach.. In this study, we encourage students to engage in the patterns suggested above through the use of visualizations of the problem space that we create though our Room-Metaphor and Test-Case approaches (described below) in a computer environment. Yazdani (2008) also found that asking students to draw a picture, figure, table or graph

greatly improved students ability to grasp problems on which reversal errors had previously been made and found that visualizations helped students detect errors and see limitations in previously used strategies. In this study, we focus on a visualization of the mathematical expressions themselves in an effort to further enhance students' abilities to solve word problems without the reversal error.

Framework

Zazkis, Dubinsky, and Dautermann's (1996) Visualization/Analysis (V/A) model suggests that an integration and interplay of visual and analytic thinking is often needed for understanding mathematical concepts. The V/A model begins with an act of visualization, which can be the actual drawing of a picture or the expression of a mental image. This is followed by an act of analysis in which the person reasons about what was visualized. Then follows a second visualization step, enriched by the analysis, which then leads to a second act of analysis, etc. (Stylianou, 2002). As the learner develops a clearer understanding of a mathematical problem, the iterations increase in sophistication and enhance conceptual understanding (Zazkis et al., 1996; Stylianou, 2002). Stylianou (2002) expanded the framework to identify particular "analysis steps" which we have elected to use as codes (Table 1) in our data analysis to address ways in which visualization helps a learner understand SP-type problems.

Table 1: Data Codes

Code	Definition
IAC	Collect new info from a visualization to understand implications of prior actions;
MEI	Use new info gained to further explore the problem; Use patterns to refine visualization
SNG	Create a visualization to better understand the problem or next steps in problem solving
MSP	Pose questions (to one's self) to check understanding and verify correct procedures.

Methods

We interviewed engineering students as they solved SP-problems to identify possible designs for our tool, resulting in our development of two interventions to use in tandem. First, we developed an interface to prompt the use of test cases and provide instant feedback when they were not compatible with constructed equations. This strategy was included with the intention of encouraging students to adopt a substitution pattern of thinking (Clement, 1982). We also developed a second, pictorial approach called the "room metaphor" approach, which involves showing a variable as a room that holds some number of boxes. This room metaphor addresses the static comparison approach mentioned above and can help students build an understanding that a variable is not just an object, but also a "container" of objects. When an equation is entered and test cases are specified and "hovered" over with the mouse, black boxes appear in the "rooms" to show a variable has taken on a value. If values correctly satisfy the equation, black boxes will fill the blocks perfectly. For a mismatch between equation and test cases (e.g., $P = 6S$, $P = 1$ and $S = 6$), empty spaces appear as a visual cue to indicate an error (see Figure 1).

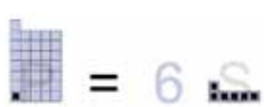

Figure 1: Feedback With Incorrect Equation And Correct Test-Case Values

To test the tool, we created five SP-type problems (see Table 2).

Table 2: Tasks Used in the Study

P1. A shoe store has four times as many pairs of leather boots as suede boots. Write an equation to represent this relationship.
P2. The gravity on the earth is six times greater than on the moon. Write an equation about this relationship.
P3. A country exports twelve times as much oil as coal. Write an equation for the relationship between the amount of oil and coal.
P4. The Yi Company produces chairs that have a seat piece and four leg pieces. Write an equation representing the relationship between the number of seats and legs.
P5. A landscape designer is designing a garden. He plans to insert six cherry trees for every ten holly trees. Write an equation using C and H to represent the above relationship.

Findings

We share our analysis of one case study, Nicole, a junior Industrial Engineering major. In P1 and P2 Nicole was able to create a correct model with little trouble. In both cases, there was evidence that she took time to think about the problem before coming up with the model. For example, she told the interviewer, "I had to figure out which side the six and one need to be on." On problem 3, however, Nicole encountered difficulty. Table 3, shows segmented transcript lines of this problem with accompanying data codes.

Table 3: Transcript Analysis of P3

Line	Transcript	Code
1	**N:** A country exports 12 times as much oil as coal. So coal equals oil	SNG
2	And if you have one coal, then you have 12 oil.(types $C = 12O$)	
3	If you have 12 coal, you have one oil (Types C=12, O=1 in test cases).	IAC
4	(Pause while she studies problem and hovers over test cases).	
5	If you have...you know you need more…. Twelve times as much oil as coal. So there is more oil than there is coal, so my equation is flipped?	MEI
6	(pauses) Yes! Ok, my equation is flipped.	SNG
	I: *Do you feel the picture helped you figure out there was something wrong here?*	
7	**N:** In this case it did help me since reading the problem, you need more oil than coal so when you see the boxes with variables, you know I wrote the equation wrong, because I was like, why do I have so many coals? (refers to picture).	IAC
8	I need more oils than I have coals.	MSP
	I: *If you had put the test case in first in this one instead of the equation, do you think it could have helped you avoid the mistake?*	
9	**N:** The test case might have helped me think about the equation, but it is a little confusing that the 12 goes...like in the equation it's 12 C, but when you do the test cases it's 12 under the O column.	MSP
		IAC
		MEI

In line 2, Nicole seems to have used a static comparison strategy where *C* stands for "coal," not amount of coal. She states that if you have 1 coal, you have 12 oil, but then in line three she uses the equation she has created rather than her previous thinking to put in the test cases *C*=12 and *O*=1. In line 4, something perturbs Nicole's thinking as she hovers over her test cases in the tool. She uses the visualization produced to understand the implications of her placement of the 12. In lines 7 and 8, she explains that the fact that there were more boxes attached to coal when she expected more under oil changed her thinking about the problem. Even though her test case and equation matched, the room metaphor helped her recognize an error in her thinking. Without this perturbation, Nicole admitted that she "probably would have just gone with her first answer."

In response to the interviewer's question in line 8, she identifies that it is counterintuitive to know that the test case value of *O* is 12, but that in the equation the 12 is attached to the *C*. This pattern that she now notices and reflects on in lines 9 represents a turning point in Nicole's thinking about these problems, making the MEI analysis a key step in her thinking.

In P4 and P5, Nicole repeatedly referred back to what she learned from her mistake in P3. In P4, she explains, "Well, for every one seat you need four legs. So since I messed this up in the last equation, I know that 4 goes with the *S*, and that equals *L*." From her discussion, it seems reasonable to assume that Nicole is not just creating the correct equation by blindly following a new procedure she developed in her work on P3, but can explain the relationship between S and L as an equivalence relationship rather than as a ratio or correspondence.

Conclusions

We feel the dynamic connection of numeric, verbal, and symbolic representations helped Nicole interact with the problem more efficiently. She used visualizations to collect useful information, allowing her to view the problem from different perspectives and further understand the need for a balanced relationship in the model. In general, when working with simple linear relationships, we need to help students move away from static comparison and direct translation habits and understand the equal sign as representing a balanced relationship. We feel this tool is one useful way of helping students reorganize their thinking on these problems.

BROADENING STEM OPPORTUNITIES THROUGH INFORMAL EDUCATION

Jacqueline Leonard
University of Wyoming

Geeta Verma
University of Colorado Denver
geeta.verma@ucdenver.edu

This report presents the results of an interdisciplinary math and science project entitled Dinosaurs, Denver and Climate Change. Children (aged 8-13) participated in multi-aged groups to learn math within the context of paleontology and climate change. Near peer mentors (NPMs) were assigned to work with small groups of students. The goals of the project were to increase STEM content knowledge among participants and to impact STEM attitudes among NPMs. STEM professionals in geology and soil science led field-based lessons relative to their disciplines. This paper reports on the results of the fall 2012 Saturday STEM program that focused on geology and paleontology.

Keywords: Informal Education, Affect, Emotion, Beliefs and Attitudes

Introduction

STEM occupations are projected to grow by 17% from 2008-2018, compared to 9.8 percent growth for non-STEM occupations, and STEM jobs are expected to grow three times as fast as non-STEM jobs (Langdon et al., 2011). While our economy depends on the talents and skills of STEM workers, only 3% of Blacks and Hispanics hold technical or STEM jobs (Baine, n.d.). We believe preparing students of color to fill STEM jobs in the U.S. is a priority. One barrier, however, is curricular support for student-directed, inquiry-based science rarely occurs in our nation's schools (DeJarnette, 2012).

To address this problem, we developed an out-of-school community-based program called Dinosaurs, Denver and Climate Change (D2C2). Our goals were twofold: (1) to impact the interdisciplinary content knowledge of math and science for children in grades three to eight; and (2) to influence the attitudes of near peer mentors (NPMs) toward STEM and STEM careers. The NPMs in this study were high school and college students (aged 16-22) who had strong interests in STEM or education.

Theoretical Framework

Place-based education emerged in rural Alaska in the 1980s (Howley et al., 2011) and operates under the assumption that education is not *place-less* but grounded *somewhere* in order for learning to take place (Aikenhead, Barton Calabrese, & Chinn, 2006). Likewise, place is not devoid of culture. Culture and place are intertwined because *place* incorporates all of the spaces in which we live and interact—locally and globally (Aikenhead et al., 2006; hooks, 2009; McInerney, Smyth & Down, 2011). *Belonging: A Culture of Place* captures this concept well as bell hooks reclaims *place* by returning to her birthplace in rural Kentucky after an academic career in New York. The places where children reside—urban, suburban or rural—create opportunities as well as challenges when it comes to learning outcomes and educational attainment (Morris & Monroe, 2009; Tate, 2008). We use the framework of place within a sociocultural context to examine and explore student learning in authentic settings where underrepresented minority students can develop literacies in STEM (Aikenhead et al., 2006; McInerney et al., 2011).

Literature Review

Research suggests that the optimum time to create interest, awareness, and connections to STEM careers is during the elementary school years (DeJarnette, 2012). Exposure to STEM content and

inquiry in math and science at earlier ages provides a foundation for interactive problem-based learning (DeJarnette, 2012; Leonard, Barnes-Johnson, Dantley, & Kimber, 2011). Science camps and afterschool programs provide a context for younger children to develop "cognitive abilities to engage in STEM content and problem solving activities" (DeJarnette, 2012, p. 80). Activities such as gardening and soil sampling, have been used to facilitate cross-disciplinary applications (Czerniak, 2007) and to foster inquiry, science literacy, and a sense of place and belonging among young children (Rye et al., 2012). In such settings, children learn science processes by manipulating a single variable to learn how it impacts the results (Rye et al., 2012). In this study, we used place-based education as a hook to encourage STEM learning.

In addition to promoting STEM learning at early ages, research also shows that peer mentoring programs where teenagers mentor young children is a growing trend (Karcher, Davidson, Rhodes & Herrera, 2010). However, the findings are mixed concerning the impact that peer mentoring programs have on mentees as well as the mentors themselves. Cross-age peer mentors can develop the following attributes: competence, confidence, connection, character, caring, (Lerner et al. as cited in Karcher et al., 2010) and contribution (Karcher et al., 2010). In this study, NPMs worked with children in small groups to help facilitate STEM learning, which had the potential to improve their competence, confidence, character and caring.

Methodology

We recruited children from African American and Latino churches in Denver, Colorado, to participate in the D2C2 program. Ten children were recruited from the African American community in Northeast Denver, and 22 children were recruited from the Latino community in Southwest Denver. Because we wanted to keep the groups small and learn from our practice, we ran two separate Saturday science camps in each community—one in October and one in November. The instructor for both groups was a retired geologist and docent at Dinosaur Ridge. He developed the lesson plans, which included field-based activities that allowed the children to explore Dinosaur Ridge.

In addition to the instructor, NPMs were hired to help facilitate the learning. Eight NPMs were hired at each site for a total of 16 mentors. Seven were male and nine were female. The NPMs went through a four-hour training session that was led by the geologist to familiarize them with the lessons and the science concepts. Moreover, the NPMs were responsible for using flipcams to record what was going on in their groups during informal science lessons. We intended to impact NPMs' attitudes about STEM indirectly as they served as mentors and group leaders during the STEM activities.

Data Sources

Quantitative data sources included a pre-post test to ascertain participants' learning. The geologist developed the test, which contained 13 multiple-choice and two open-ended questions to measure children's geoscience content knowledge. Qualitative data sources included video clips, work samples, and structured interviews with the children and NPMs who participated in the D2C2 program.

Results

Since the children at both sites received the same treatment, the data were combined to analyze the results. If these data were analyzed separately, the results would suffer from low statistical power. The results of the fall study revealed significant improvement on the geoscience test: (t = -4.63, p < .001, two-tailed). The results are shown in Table 1.

Table 1: Results of Geoscience Test

Geoscience Test (N=20)	Mean	Std. Deviation
Pre-test	61.55	19.15
Post-test	71.05*	15.92

Analysis of the quantitative data revealed that children did better on the open-ended items (86% accuracy) on the geoscience post-test. Further item analysis revealed two math-related multiple-choice items were difficult for students. Seventy-two percent of the students missed the following question: Dinosaurs lived (A) From about 25,000 – 50,000 years ago; (B) About 2 billion years ago; (3) From 225 million – 650 million years ago; (D) Around 450 BC. The correct answer is C. Sixty-four percent missed another math-related question: The earth is about 4.6 billion years old. The dinosaurs lived on the earth (A) Near the beginning of time; (B) About halfway through this time; (C) In the most recent 5% of earth's history. The correct answer is C. Results of the STEM Semantics Survey (Kenzek & Christensen, 2008) revealed no significant differences among the interns' attitudes about STEM and STEM careers with the exception of technology (t = -2.27; p < .001; two-tailed), which was not surprising given the use of the flipcams.

In addition to the qualitative data, student work samples revealed fairly accurate measures and calculations to determine from dinosaur tracks if the dinosaur was walking, trotting, or running. Students measured the hip height (201–214 cm) and stride length (590–600 cm) of a Stegosaurus and divided the stride length (SL) by the hip height (h) (2.8–2.9) to determine the dinosaur was most likely trotting (SL/h ratio of 2.0–2.9). Other qualitative data included excerpts from a questionnaire (interns) and focus group interviews (student participants).

> I liked how all of us just interacted with the different types of fossils, and we all got our hands on 'em, and we all got to see. We didn't just see it on a picture or on a poster. We actually went to it and touched and saw it and took pictures of it. I liked how we just got to interact with that and measure by ourselves and not by looking at a certain picture. (D2C2 student, Group Interview)

> What interested me in the program is that it is not your average program. We actually got to learn while teaching. I did not know as much as I do now about dinosaurs, and I thought it would be fun to learn about them while working with the youth. (D2C2 intern, Questionnaire)

Discussion

The results of the pre-post tests suggest children in this study may have had limited opportunities to learn number sense and percent. Millions and billions of years is not an easy concept to comprehend. It is also a common misconception that dinosaurs lived near the beginning of time. Simply *teaching by telling* students about the Jurassic and Cretaceous periods, creating a timeline, and seeing a visual display at a museum are not enough. Results suggest that STEM educators should use *place* to develop rich meaningful activities to ensure students' understanding. For example, a Facebook page now has a timeline from birth to the present of significant events in a person's life. Five percent of the timeline would be an example of when dinosaurs lived on the earth. Moreover, *culture* may be used to help children to understand academic language in STEM. What cultural term may help children to understand the continuum of time? *Before zero-dark thirty, zero-dark-thirty, and after zero dark-thirty*?

The results of the qualitative data reveal the salience of place for the participants. Being outdoors and actually touching the fossils was important to several children. For the interns, both place and competencies emerged (Karcher et al., 2010). Being able to make a *contribution* and gaining *competence* and *confidence* was important to the interns.

Significance

The findings presented in this brief report show that *place* is important in the learning context, particularly in STEM education. The backdrop of Dinosaur Ridge provided the children with remarkable experiences. Mathematics teachers and educators should not minimize the value of connecting math concepts (i.e., measurement, number, & number sense) to place-based experiences. D2C2 provided the resources for underserved youth to learn about geoscience by directly experiencing it through Colorado's natural resources.

Studenting is comprised of the behaviours that students perform or exhibit in a learning situation, such as the classroom. Student actions that do not contribute to actual learning and that subvert the intentions of the teacher are a subset of studenting behaviours that we call gaming behaviours. In the research that we present here we confirm a taxonomy of studenting behaviours around the way grade 10-12 students do homework. This paper describes these gaming behaviours and reports results showing that 65% of studenting behaviour observed subvert the intentions of the teacher.

Keywords: High School Education, Instructional Activities and Practices

Introduction

The term studenting was coined by Gary Fenstermacher to describe what students do to help themselves learn. These student activities include recitation, practice, seeking assistance, reviewing, checking, locating sources and accessing material, among others (Fenstermacher, 1986). However, studenting also encompasses behaviours that are less concerned with learning and more concerned with:

> 'psyching out' teachers, figuring out how to get certain grades, 'beating the system', dealing with boredom so that it is not obvious to teachers, negotiating the best deals on reading and writing assignments, threading the right line between curricular and extra-curricular activities, and determining what is likely to be on the test and what is not. (Fenstermacher, 1994, p.1)

The concept of studenting allows us to broaden our exploration into, and discussion about, what students do in learning situations, such as the classroom, and specifically those features of student behaviour that do not align with the goals of the teacher. Consider the following anecdote:

> With about half an hour left in class Mr. Count assigns some homework. Nadine spends the class time carefully writing out the assigned page and problem numbers, neatly writing her name and the date, and reading her notes. Later that evening she neatly copies the procedures that her tutor directs her to do. She feels that because she 'did' the problems, she understands the concepts.

From Mr. Count's perspective, although she did not work during class, Nadine has learned the material – she has completed the homework problems and shown all of the work. From Nadine's perspective, she is reducing her overall effort by waiting until she has her tutor with her to guide her. As long as she has fulfilled her obligation to 'do' the problems and has written up the solutions, Nadine feels she has met the expectations. There is a rationality to Nadine's actions, but she is not learning, at least not how Mr. Count intended. She is studenting, and in a way that subverts the teacher's intentions yet appears to achieve the required outcomes, thus beating the system.

It is exactly these aspects of studenting that we are interested in. More specifically, we are interested in the studenting behaviours that are not in alignment with the teacher's goals and expected actions, yet may be missed by the teacher during the activities of teaching. We refer to

this class of studenting behaviours as gaming behaviour, as in the students are gaming the system. The notion of gaming extends constructs such as didactic contracts (Brousseau, 1997) and norms (Cobb, Wood, & Yackel, 1991; Yackel & Cobb, 1996).

Methodology

Data for this study is taken from a larger, ongoing project studying studenting behaviour within several mathematics classrooms across a large number of contexts. A grounded theory approach is used to continually analyse data as it is collected. Over time, this analysis has revealed a number of interesting student behaviours within different contexts. The ongoing coding of the variety of studenting behaviours becomes easier as behaviours become known and eventually a saturation point is reached when new observations in a particular context reveal no new studenting behaviours.

Context

Homework is something that every teacher in our study assigned on a regular basis. In some classes homework is worth marks and in other classes it is not. After studying studenting behaviour with regards to homework in a number of grade 10-12 (ages 15-18) classrooms we had reached a saturation point around the context of how students engage in this activity.

Data

The data for what we present here comes from five different classrooms. There were two grade 10 (ages 15-16) classrooms, two grade 11 (ages 16-17) classrooms, and one grade 12 classroom (ages 17-18). In the two grade 10 classrooms and one of the grade 11 classrooms homework was checked and it was worth marks. For two of the teachers homework was checked randomly on occasion and a completion mark was assigned (or not). In the third classroom homework was handed in once a week and a number of questions were selected at random and marked. In the remaining two classrooms homework was not checked and not marked.

In each of these classrooms we interviewed 20 students selected at random. The interviews were short (1-4 minutes) and were audio recorded using a portable digital recorder. For the most part these interviews consisted of a brief answer to the questions "Did you get your homework done for today?", "If so, how did you go about getting it done?", "If not, why not?". Depending on their answers to the second question posed to them there were more questions regarding their reasons for their behaviour. These interviews occurred in the moments before the beginning of the lesson, during homework checks, within breaks in the lesson, and immediately after the lesson if the school schedule permitted it. This was not foreign to the students as the lead author had spent several lessons doing similar questioning in the same classes regarding a variety of learning contexts. In all, data from 100 interviews was collected by the two authors over the course of two lessons per classroom. Added to the above data were lengthier interviews with the teachers regarding their intentions for assigning homework prior to the lessons in which we collected the data as well as their responses to the results of our analysis. These interviews were also audio recorded.

Analysis

As mentioned, these data were analysed immediatiately after collection. Initially these were analysed using a framework of grounded theory. However, as the study progressed, and a taxonomy of behaviours began to emerge, subsequent data was analysed using a framework of analytic induction (Patton, 2002). “[A]nalytic induction, in contrast to grounded theory, begins with an analyst's deduced propositions or theory-derived hypotheses and is a procedure for verifying theories and propositions based on qualitative data” (Taylor & Bogdan, 1984, p. 127 cited in Patton, 2002, p. 454). In this case, the theory informing the analysis was the emergent

taxonomy of studenting behaviour with regards to homework. This is not to say that we were not open to the emergence of new themes, because we were.

Results

From the analysis of the data a taxonomy of four behaviours emerged: *didn't do it*, *cheated*, *got help*, and *did it on their own*. In many ways, these behaviours are obvious. However, beneath each of these obvious studenting behaviours lay less than obvious results revealed following deeper investigation and our analysis. Due to space constraints we include here only the table summarizing the distribution of behaviours (table 1).

Table 1: Distribution of Behaviours

Discussion

	Marked (n=60)	Not Marked (n=40)
Didn't Do It	**15**	**16**
I forgot	5	3
I was busy	4	2
I tried, but I couldn't do it	3	3
I took a chance	3	0
It wasn't worth marks	0	8
Cheated	**14**	**1**
Copied	7	1
Faked	5	0
Half homework risk	2	0
Got Help	**18**	**12**
Felt they would fail quiz	6	1
Felt they would pass quiz	3	3
Felt they would excel at quiz	9	8
Did it On Their Own	**13**	**11**
Mimicked from notes	4	5
Did not mimic from notes	6	6
Mimicked but completed	3	0

Although the sample sizes were too small to make any broad generalizations we did notice some very stark contrasts between the classrooms where homework was marked versus those classes where homework was not marked. In particular, there was a clear difference in the number of students not doing the homework and cheating. This prompted us to consider the behaviours across the marked/not marked divide (see table 1).

Looking at these numbers it is clear that a larger percentage of students in the classes where homework was not worth marks didn't do homework (40%) in comparison to the classes where homework was worth marks (25%). This is not surprising. We know that marks are an incredibly powerful tool for motivating student behaviour. But does it motivate the behaviour that we want? Cheating and getting help with homework only for the purposes of collecting marks are behaviours that all five teachers agreed subvert their intentions, albeit in ways that are much less visible to them. Taking these three behaviours together (not doing homework, cheating, and getting help only to get marks) provides quite a different set of results. For the classes where homework is worth marks these three behaviours account for 58% of student behaviour vis-à-vis homework, whereas in the classes where homework is not worth marks they only account for 45% of the behaviours.

Present within both the marked and unmarked classes was evidence of mimicking. Mimicking occurs when the students rely not on understanding as much as simply following the

solution pattern laid down by the teacher in an example problem. We know from prior research (Liljedahl & Allan, under review) that this behaviour may subvert a teacher's intentions. So it was in this study. The five teachers in this study all stated that the purpose of homework was for students to test their understanding of, and abilities with, new content. Mimicking, they felt, does not provide students with an accurate indication of either their understanding or their ability. As such, if we factor these into the above analysis then subversive behaviours account for 70% and 58% of the behaviours for the classes where homework is worth marks and the classes where homework is not marked respectively. Combining the two groups of participants we get that 65% of the students exhibited studenting behaviour that was viewed by both us and the teachers as subverting the intentions of the teachers.

Conclusions

These findings are consistent with our research in other contexts as well. Across the board students are finding ways to subvert the expectations of the teacher in ways that the teacher is not aware of. In many cases these behaviours are centred on proxies for learning and understanding, such as mimicking and overemphasis on note-taking, that are not actually conducive to learning – but appear to be in alignment with the teacher's goals.

From the perspective of the student, however, there is a certain rationality to their actions that we are trying to understand using theories from behavioural economics, such as minimisation of effort, economy of action, bounded rationality (Simon, 1955), loss aversion, and risk aversion.

From the perspective of the researcher we are also exploring ways to think more deeply about the classification of some of these behavioral categories as subversive. For example, although there were two students who were playing the system by completing only half of the assigned homework it is not entirely clear to us if they are subverting the teachers' intentions, or the opportunity to learn, or both. Likewise, the three students who used mimicking in their homework extensively but then extended their learning from these solutions in order to complete questions not demonstrated in class were perhaps not subverting the teacher or their learning.

Finally, it is worth noting that since we brought to the attention of the teachers in this study the results of the analysis and the emergent taxonomy they have all begun to explore alternatives to their current practices vis-à-vis homework. It seems as though the kind of knowledge generated by research into the gaming aspects of studenting behaviour can be a powerful catalyst for initiating teacher change.

RACE-PLACE IN MATHEMATICS PARTICIPATION: LATINA/O UNDERGRADUATE STUDENTS' NEGOTIATIONS OF RACIALIZED SPACES AND IDENTITIES

Sarah Oppland-Cordell
Northeastern Illinois University
s-cordell@neiu.edu

This study investigates four Latina/o undergraduate students' perceptions of how their negotiations of racialized spaces throughout their academic and mathematical lives impacted their identity development as mathematics learners. Racialized spaces were analyzed in: 1) broader societal, community, family, and school contexts, 2) a required calculus I course, and 3) an optional Emerging Scholars Program, calculus I workshop. Participants revealed that powerful racialized experiences tied to broader contexts both hindered and supported their strengthened mathematics identity development. While (re)negotiating and resisting a subset of these experiences in racialized spaces in the workshop contributed to strengthening participants' mathematics identities, negotiating racialized spaces in the required calculus I course did not have this same impact.

Keywords: Equity and Diversity, Gender, Post-Secondary Education

Purpose and Background

In mathematics education scholarship, additional information is needed regarding the complexities underlying Latina/o students' mathematics participation and learning processes that contribute to their mathematical success. Although there is evidence that Latina/o students' experiences in broader sociopolitical contexts (e.g., societal, community, school, family) impacts their mathematics achievement levels (Ortiz-Franco & Flores, 2001), additional in-depth explorations of how Latina/o students manage experiences within broader contexts in relation to their mathematical development are needed. Although sociopolitical constructs (e.g., race, gender, and class) influence underrepresented students' mathematics participation and learning (Martin, 2009), there is a lack of information about how Latina/o students' negotiations of racialized, gendered, and classed spaces in mathematics classrooms influences their mathematical development. Viewing mathematics classrooms as comprised of racialized, gendered, and classed spaces and situating them within broader sociopolitical contexts can aid in uncovering information about how and why Latina/o students succeed in mathematics.

This study investigates four Latina/o undergraduate students' perceptions of the racialized spaces they negotiated throughout their academic and mathematical lives. I explored how participants managed racialized spaces in: 1) broader societal, community, family, and school contexts, 2) a required calculus I course (lecture and discussion section), and 3) an optional Emerging Scholars Program (ESP), calculus I workshop. I aimed to understand how their negotiations of racialized spaces within each context and across all contexts influenced their mathematics identity constructions. This analysis contributes to a deeper understanding of linkages among Latina/o students' negotiations of racialized spaces, their mathematics participation and learning, and their success in culturally diverse, collaborative math classrooms.

Perspective

A deeper understanding of the mechanisms underlying Latina/o students' mathematics participation and learning that contribute to their mathematical success can be achieved by using an equity lens that embraces the sociopolitical turn in mathematics education. Advocates of the sociopolitical turn in mathematics education (Gutiérrez, 2010) support the use of critical race theory (CRT) and Latina/o critical theory (LatCrit) to examine marginalized students' mathematics experiences. In this study, applying CRT and LatCrit (Solórzano & Delgado Bernal, 2001) allowed for capturing Latina/o students' perceptions of the historical, sociopolitical, and situational nature of racialized spaces, including the salience of gender, class, and power.

In this study, spaces refer to "intersections of symbolic (personal, social, ideological, political) and physical dimensions, where issues of power, hegemony, agency, structure, control, and knowledge define boundaries that have varying degrees of flexibility and permeability" (Varelas, Kane, & Pappas, 2010, p. 4). Since school spaces are racialized (Barajas & Ronnkvist, 2007), the calculus contexts examined in this study are seen as comprised of racialized spaces (while also embracing how gendered and classed experiences may function within these spaces). Research has documented how Latina/o students manage racialized (Fernández, 2002), gendered (Jilk, 2006), and classed (Ortiz-Franco & Flores, 2001) experiences in mathematics classrooms.

Method

This study is part of a larger study on Latina/o students' identity and participation in an ESP calculus I workshop at Hall University, a predominately White university in Chicago, Illinois (Oppland, 2010). In this larger study, I analyzed how participants co-constructed mathematics and racial identities, how their workshop participatory trajectories developed over time, and how their mathematics and racial identities strengthened their participation. This study expands upon prior findings by examining how four Latina/o students negotiated racialized spaces throughout their academic and mathematical lives. Participants include Vanessa[1] (18-year-old female), Lilliana (19-year-old female), Immanuel (19-year-old male), and Dante (18-year-old male).

Participants were simultaneously enrolled in a required calculus I lecture and discussion section, and an optional ESP calculus I workshop. The workshop was modeled after Uri Treisman's doctoral dissertation work, which aimed to discover explanations for why African American students were struggling to learn calculus at the University of California, Berkley in the mid-1970's. Drawing on this model, the optional mathematics workshops at Hall run parallel to students' standard mathematics courses and encourage culturally diverse peer groups to collaboratively solve challenging worksheet problems. Workshops are held for two hours either once or twice per week, and are worth 1 credit hour (satisfactory or unsatisfactory). The workshop in which this study took place consisted of 27 students. Class demographics were approximately 41% Latina/o (4 females and 7 males), 30% Asian (5 females and 3 males), 22% White (2 female and 4 males), 7% African American (1 female and 1 male), and 44% female.

This qualitative study used multi-case study analysis (Yin, 2009) and counterstorytelling methods (Solórzano & Yosso, 2002). Three semi-structured interviews were analyzed to construct an in-depth case study for each participant. Data analysis involved coding interview data, constructing thematic memos, and writing narrative summaries that described the racialized experiences participants negotiated in broader contexts, the racialized spaces participants managed in the mathematics classroom contexts examined, and how this management of

[1] Vanessa and the names of all people and places used in this article are pseudonyms.

racialized spaces within and across these contexts impacted their identities as mathematics learners. A cross-case analysis was also conducted on the four case studies.

Results

Each participant negotiated racialized academic and mathematical experiences in all the broader contexts examined. Table 1 displays examples of racialized academic and mathematical experiences participants managed in broader contexts that acted as possible avenues or barriers for their strengthened mathematics identity development. Participants tended to describe more potential barriers than avenues for their strengthened mathematics identity development in *societal*, *community*, and *school* contexts. Participants also tended to describe more avenues than barriers for their strengthened mathematics identity development in *family* contexts. These racialized experiences also intersected with gendered and classed experiences in some instances.

Table 1: Examples of Racialized Academic and Mathematical Experiences Negotiated

Broader Sociopolitical Context Examined	Examples of Racialized Academic and Mathematical Experiences Negotiated (Possible Avenues for Strengthened Mathematics Identity Development)	Examples of Racialized Academic and Mathematical Experiences Negotiated (Possible Barriers for Strengthened Mathematics Identity Development)
Societal	**[Immanuel and Lilliana only; Vanessa and Dante did not provide examples for this category]** Had an awareness of broader societal messages that supported the notion that fair educational, mathematical, and/or occupational opportunities existed for all students, regardless of their cultural backgrounds	**[Vanessa, Immanuel, Lilliana, Dante]** Had a keen awareness of broader societal messages that supported the notion of a racial hierarchy of academic and math ability that positioned Latinas/os (and African Americans) as inferior and other cultural groups as superior (e.g., Asians)
Community	**[Vanessa, Immanuel, Lilliana, Dante]** Encountered community members who resisted negative societal messages about their academic and/or mathematics abilities	**[Vanessa, Immanuel, Lilliana, Dante]** Believed they experienced a lack of academic and math resources and/or role models
Family	**[Vanessa, Immanuel, Lilliana, Dante]** Believed their parents motivated them to succeed in education, mathematics, and life	**[Vanessa, Immanuel, Lilliana, Dante]** Believed their families' socioeconomic status levels contributed to creating academic and mathematical disadvantages
School	**[Vanessa, Immanuel, Lilliana, Dante]** Viewed their interactions with culturally diverse peer populations in math classrooms as a positive experience (this allowed some participants to challenge math stereotypes about certain cultural groups)	**[Vanessa, Immanuel, Lilliana, Dante]** Experienced lower-quality educational and math experiences in K-12 settings, including due to weak curriculums, less-qualified teachers, lack of funding, tracking practices, and/or racialized experiences involving teachers and/or peers

Racialized experiences participants negotiated in broader contexts that seemed to act as significant barriers for their strengthened mathematics identity development included: (a) negotiating socially constructed meanings projected onto the Latina/o marker related to academics and mathematics in societal, community, and school contexts and (b) negotiating racialized school experiences. Racialized experiences participants negotiated that appeared to serve as important avenues for their strengthened mathematics identity development included: (a) resisting negative racialized experiences in societal, community, and school contexts and (b) negotiating positive racialized experiences in family, community, and school contexts.

Participants revealed that a subset of racialized experiences they negotiated in broader contexts became manifested in the workshop context, including experiences that seemed to act as significant barriers for their mathematics identity development. However, they provided powerful accounts of how they (re)negotiated and resisted harmful racialized experiences tied to broader contexts mainly through peer interactions, which strengthened their identities as mathematics learners (including as Latina/o). However, in their lecture and discussion sections, where participants encountered fewer opportunities to interact with peers, they did not describe their negotiations of racialized experiences that were disjoint from their workshop experiences as playing a significant role in strengthening their mathematics identity constructions.

Conclusion

This study raises important considerations regarding the significance of understanding *what it means to be* a *Latina/o* with respect to mathematics participation, learning, and success. Participants' counterstories reveal how Latina/o students might (re)negotiate and resist racialized experiences through peer interactions in diverse, collaborative mathematics learning settings situated in broader sociopolitical contexts. This study suggests that providing Latina/o students with opportunities to engage in mathematical group work may offer them additional opportunities (as compared to within traditional mathematics learning contexts) to negotiate meanings for race and racism in ways that supports their strengthened mathematical identity development. However, this study also suggests that even if ESP-type learning environments assist marginalized students in overcoming racialized barriers and experiencing mathematical success, additional support systems within the broader sociopolitical environment, including within larger mathematics department settings, are needed to minimize or eliminate the inequities they experience as mathematics students in our schools, societies, and world.

USING CLINICAL INTERVIEWS TO UNDERSTAND STUDENTS' LEARNING PROCESSES IN A TECHNOLOGICAL ENVIRONMENT

S. Aslı Özgün-Koca
Wayne State University
aokoca@wayne.edu

Thomas G. Edwards
Wayne State University
t.g.edwards@wayne.edu

The goal of this study was to better understand student learning when using TI-Nspire to study quadratic functions. We conducted clinical interviews with pairs of students who worked on three activities aimed at understanding the effects of each coefficient in the quadratic function. Data analysis revealed various ways students interact with multiple dynamically-linked representations and how they interpret the results of their actions on those representations.
]

Keywords: Technology, Clinical Interviews, Multiple Representations

Introduction

The National Council of Teachers of Mathematics (NCTM, 2008) asserts "technology is an essential tool for learning mathematics in the 21st century… When technology is used strategically, it can provide access to mathematics for all students" (p. 1). Technology can help students visualize abstract mathematical concepts and enable them to explore and conjecture. *Common Core State Standards* (2011) echoes this view: "When making mathematical models, they know that technology can enable them to visualize the results of varying assumptions, explore consequences, and compare predictions with data" (p. 7). These statements bring important questions to the forefront: Do students using technology (e.g., TI-Nspire) require scaffolding to support their mathematical learning? If so, what sort of scaffolding do they need?

A change in individuals' mathematical thinking as a result of activity/experience supported by technology is a theme that emerges from research (Heid & Blume, 2008). Moreover, they cite the effective use of multiple dynamically linked representations as one of the primary features of mathematical technology enabling this procedural-to-conceptual shift.

The main goal of this study was to better understand students' learning processes when TI-Nspire is used to conduct an activity on quadratic functions. Therefore, our research question is: When students use dynamically linked multiple representations, what limits their ability to bring mathematical concepts to their consciousness (Heid & Blume, 2008)?

Conceptual Framework

In the mathematics education literature, we see the dichotomy of external representations, the signs and symbols we create for ideas, versus internal representations of those ideas that exist only in our minds (Janvier, Girardon, & Morand, 1993). Similarly, NCTM (2000) confirms this dichotomy by defining representation as referring "both to process and to product—in other words, to the act of capturing a mathematical concept or relationship in some form and to the form itself." (p. 67). Technology changes the forms and capabilities of external representations.

Zbiek, Heid, Blume, & Dick (2007) view technology as a cognitive tool enabling students to access, experience and study mathematics at new levels. Dick (2008) posits that effective use of technology in an educational setting should have pedagogical, content, and cognitive fidelity. According to Dick, when students learn mathematics, they act on objects, observe the results of doing so, and reflect on its meaning. He also argues that student reflection feeds a prediction-conjecture-testing cycle which may lead to acceptance or rejection of the conjecture. From this perspective, Dick links what it means to be a pedagogically faithful technological tool to student

perceptions of the tool as enabling the creation of objects and actions on those objects, as well as providing evidence of the consequences of those actions.

Chua and Wu (2005) introduced a similar framework for constructivist learning using a technological tool. Their framework includes exploring, conjecturing, and verifying, followed by generalizing. When exploring, students inquire about and investigate a given task. Next, they conjecture, making inferences and judgments using intuition or evidence. When verifying, students test and check “the appropriateness and reasonableness of their conjectures” (p. 389). Finally students are asked to generalize their solution, thereby moving the task to higher ground.

Combining frameworks, experimenting in a technological environment is cyclic (see Figure 1). It starts with a carefully designed task. How we scaffold student work is as important as the affordances of the technology. Before students use the technology, we may ask them to predict what will happen. Asking for predictions prepares their minds for the task and makes use of prior mathematical knowledge. Next, they interact with the technology. Doing so offers them opportunities to create and act on external representations. Observing the consequences of those actions, students might see a pattern leading to a conjecture. Then they might repeat several cycles of exploring, conjecturing and testing, especially if their conjecture does not hold. Once they solidify the conjecture, they can generalize via proving or refuting the conjecture.

Figure 1. Framework

Data Collections and Analysis Methods

The participants in this study were 7th or 8th grade students enrolled in pre-algebra or algebra in a public school near a large city in the Midwest. The study was conducted in the early spring of two consecutive school years. The capabilities of TI-Nspire calculators make novel classroom activities possible. Students can dynamically manipulate a graph and observe the effects of that manipulation on its symbolic form. We created activities using TI-Nspire in which students used dynamically-linked representations to drag and bend the graph of a quadratic function to study the relationship between each of its coefficients and the graph (see Özgün-Koca & Edwards, 2008, Edwards & Özgün-Koca, 2009). The students had previously studied quadratic functions.

We conducted clinical interviews of pairs of students. For most of the students, this was the first time that they had used TI-Nspire. Interview questions mirrored the activity. Follow-up questions elicited students’ thinking. Each interview was video-recorded. The interviews took about 50 minutes each. Investigator field notes and students’ worksheets were also collected.

Video recordings of the clinical interviews were transcribed. To analyze these data, the investigators developed a set of codes used to reveal patterns and themes. Then each investigator independently coded the data with about 75% agreement. When they disagreed, final codes were negotiated. If only one of them coded an item, they negotiated an agreement. Using the conceptual framework, we sought evidence of students exploring, conjecturing, testing, or generalizing. Investigator triangulation (Denzin & Lincoln, 1994) and code checking (Miles & Huberman, 1994) were used to ensure the trustworthiness of the data analysis.

Results

We saw clear patterns related to four points in our conceptual framework: task, conjecturing, testing, and exploring. When students formed conjectures, we observed conjectures that were viable, semi-viable or naïve. We also saw signs of how much scaffolding during a task was needed to support exploration. In this paper, we focus only on conjecturing, and within that, we only share results related to naïve conjectures. Students' conjectures were coded as naïve if they were based only on superficial visual features, were limited by constraints of the technological design, or were obstructed by the presence of multiple dynamic linked representations.

Superficial visual features such as a parabola appearing larger or smaller capture students' attention first. In one of the activities, students studied the effects of changing *b* in $y=ax^2+bx+c$, while keeping *a* and *c* constant. When studying the effects of changing *b*, most students talked about the parabola becoming larger or smaller when the value of *b* changed.

Male Student: When you move to the right the …, the parabola goes to the left …
Investigator: Ok, just left….
Male Student: It goes up, too ... it gets smaller….

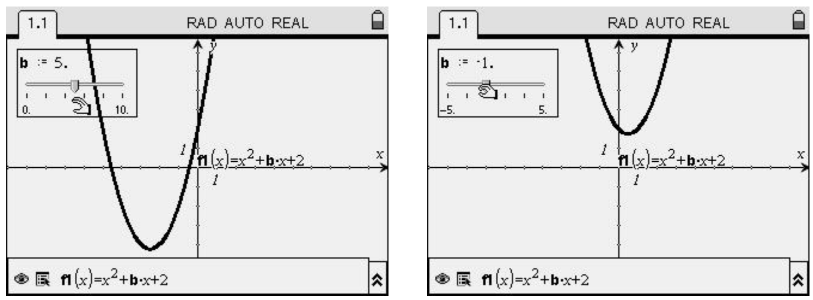

Figure 2. Studying the Effects of b

This is not wrong in a fixed window. However, we observed this repeating pattern in the data analysis. Participants generally started with one visual conjecture that is easily noticeable. Having made that one conjecture, some of them did not go any further. The main question is how to help our students to ask more "what if?" questions.

Technology can be both supportive and problematic. TI-Nspire makes it possible to grab a parabola from its vertex and translate it. The algebraic form then automatically changes to the vertex form and is continually updated. When studying how moving the graph of a parabola up and down would affect the algebraic form, the interface did not allow the parabola to be easily dragged in only the vertical direction. While trying drag up and down, there was usually also a slight movement right or left. This caused problems when we asked them to conjecture about changes in the algebraic form that resulted from dragging the parabola. Even though this is more of a technologically instigated problem, it shows the importance of the design of the task.

When there are more representations, there are more places on the screen to look. But the question is whether students are looking where we would like them to look. To study the effects of changing *b*, we designed a slider to change *b*. The goal was to create a dynamic environment. Moreover, we intended to help students connect the *value* of *b* and the location of the graph. Many made the connection between the graph and the *position* of the slider or some just focused on the slider itself (see Figure 2). Our observations confirmed the notion of Zbiek et al. (2007) that creating another representation such as a slider to control a parameter creates some added challenges. Our challenge was how to focus students' thinking on the changes in the graph and the value of *b*.

Discussion

Studying learning in a technological environment is complex. Many features of an activity greatly affect students' learning experiences in a technological environment. Our analysis of these clinical interviews showed us that students' often make naïve conjectures that interfere with their ability to bring mathematical concepts into their conscious awareness.

Clinical interviews helped us to see things we had missed in earlier whole class situations. Although each student had a calculator in the whole class situation, even with two of us in the room, it was impossible to observe how individual students were exploring and conjecturing. Moreover, most of the models explaining learning in technological environments include notions similar to exploring, conjecturing, generalizing, and so forth. However, we need to dissect these models and investigate in more detail what is happening when students make conjectures. In this study, we were able categorize some students' conjectures as naïve and suggest potential reasons that led students to make naïve conjectures. However, we had a limited number of clinical interviews conducted within a 55-minute period. Moreover, we were not able to record students' actions on the screen. More studies are necessary to better understand different characteristics of the task and technological environment that help or hinder students' experimenting processes.

The tendency of many students to make naïve conjectures clearly implies that students need scaffolding when learning in a technological environment. It appears to us that issues related to the capabilities and limitations of the technology can be at least partly mollified by acknowledging them up front. In this way, not only the technological, but also pedagogical design of the activity becomes very important. We believe that we have started to uncover some crucial aspects affecting students' experiences in technologically rich environments. However, more studies with a range of various technologies for studying different mathematical concepts are necessary to improve our conceptual framework, as well as to increase our understanding of students' learning processes in technologically rich environments.

DOCUMENTING SUPPORT FOR CHILDREN'S MATHEMATICAL THINKING IN LOW-INCOME, AFRICAN-AMERICAN CHILDREN'S HOMES

Amy Noelle Parks
University of Georgia
amyparks@uga.edu

Rachel Monette
University of Georgia
rach789@uga.edu

The purpose of this study was to explore ways in which low-income, African American mothers supported their children during an in-home activity that had the potential to elicit mathematical thinking. Six mothers were given recipes for playdough, necessary supplies, and audio recorders to capture interactions with their children while making and playing with the playdough. Analysis of transcripts showed a great deal of support offered, including eliciting mathematical thinking and talk, making connections between the activity and other contexts, and extending children's participation. These findings suggest that educators need ensure that early mathematics curricula and interventions elicit and build on parent strengths.

Keywords: Early Childhood Education, Equity and Diversity, Informal Education

Within the mathematics education community, a great deal of concern has been expressed about differences in mathematical performance across demographic groups that appear in assessments given relatively early in children's schooling (Jordan, Kaplan, Olah & Locuniak, 2006; NRC, 2009). There is some disagreement in the field about the factors that contribute to these early differences. Some researchers have argued that the quantity and quality of mathematical interactions in the homes of children located differently in terms of race, ethnicity, language, family-education, and class are central to understanding early performance gaps on mathematical assessments (e.g., Starkey & Klein, 2004; Saxe, Guberman & Gearhart, 1987). Others have argued that there are few important differences in children's homes in relation to early mathematics and that these differences appear primarily when children enter school and are then exaggerated by differential schooling practices (e.g., Ginsburg & Russell, 1981; Street, Tomlin & Baker, 2008). Understanding the role of early mathematics experiences in diverse homes is central to planning preschool and kindergarten programs, family outreach efforts, and early intervention around mathematics. The purpose of this study was to contribute to this line of work. We asked the following research question: What mathematical events occur when parents engage with their children in a guided play activity designed to elicit mathematical thinking?

Mathematics and Play

Recent research suggests that early mathematical play does lead to future learning, although there have been far fewer studies of mathematical play in homes than in schools. Levine, Ratliff, Huttenlocher and Cannon (2012) found that children who played with puzzles during observations of their at-home play performed better on a test of spatial skills given months later. Similarly, Ramani and Siegler (2008) found that playing Chutes and Ladders at home correlated with performance on tests of numeracy (unlike play with other kinds of games). In addition, a great deal of work has demonstrated that play with various kinds of blocks supports later skilled performances in mathematics (e.g., Wolfgang, Stannard & Jones, 2003).

This research suggests that we need to know more about the mathematical play children engage in while at home. However, few studies have examined mathematical play in this

context. One exception is Tudge and Doucet's (2004) study of the kinds of play engaged in by 39 diverse preschoolers, which found that about 40 percent of the children engaged in some kind of mathematical play during observations, and that while there was a great deal of variation in the amount of mathematical play observed across families, these differences were not explainable by race or class. In an ethnographic study that followed children between home and school, Anderson and Gold (2006) found that many of the mathematical practices children engaged in at home were not leveraged in school.

Interventions designed to increase the frequency or quality of mathematical engagement at home have tended to emphasize teaching parents how to do mathematical activities with their children. For example, in describing the home component of a broader study on early mathematics, Starkey and Klein (2004, p. 107) write "in a typical class, four mathematics activities were presented and parents were taught how to engage in these dyadic activities with their children." Few studies have sought to document strengths parents bring to mathematical interactions in the home – particularly in minority and low-income families – or to leverage these strengths in work with children and their families.

Mathematical Events and Practices

In this study, we draw on Street, Baker & Tomlin's (2008) work examining numeracy practices at home and at school in Great Britain. Street, Baker and Tomlin see numeracy practices as embedded in "context, values and beliefs, social, and institutional relations" (2008, p. 17). This means that when examining differences in mathematical practices enacted in homes or at school, analysis must include a recognition of the purposes the mathematics serves in the contexts and the social positions participants are seeking to occupy (knowledgeable teacher, good mother, etc.). This perspective encourages researchers to see multiple practices as productive, even if those practices may not be sensible in other contexts. Following Street, Baker and Tomlin, we talk about *events* rather than practices in this paper to differentiate between events, which are observable by anyone, and practices, which require knowledge of the intent of the participants. Although parent interviews are planned as part of this study, they have not yet been conducted. Street, Baker and Tomlin refer to "numeracy" practices and events, largely in response to particular conversations in the UK. However, we chose to use "mathematical events" because we want to be explicit that our focus includes geometry, measurement, and spatial relationships, as well as number.

Methods

The participants in this study were invited from a cohort of children that the research team has been following through ethnographic observation at school for three years. The current cohort (numbers and demographics have varied as children have moved in and out of the school) includes 16 children, six girls and 10 boys. The class includes 13 African American boys and girls, one European American girl, one Hispanic girl, and one Indian-American boy. All children in the class are eligible for free- or reduced-lunch prices. Families whose children attend the school live in one of the most rural counties in the state and many parents are raising their children in the community in which they were raised. Nearly all of the children in the cohort have siblings or cousins in the PK-12 school, which serves fewer than 300 students and has one classroom for each grade level in the elementary band.

Our study used a project reported by Anderson, Anderson and Shapiro (2004) as a model. These researchers sent home mathematics-related children's books with four dyads of middle-

class parents and children and asked parents to audio record their reading of the book to their children. For our study, all parents in the cohort were invited to participate in the playdough activity during a family math night or through a letter sent home. Seven mothers volunteered. These mothers were given a recipe for making playdough, the necessary supplies (including measuring cups and spoons), an audio recorder, and a disposable camera. The written directions asked parents to make the playdough with their children and to audio record the process as well as their children's play with the dough afterward. As part of the IRB process, parents knew the research team was interested in informal mathematics, but received no instruction about how to incorporate mathematical thinking into the activity.

Audio files were transcribed by the research team and transcripts of the activity were coded using a qualitative software analysis program. To the extent possible, the team identified mathematical events in the transcripts by attending to mathematical content (number, measurement, etc.) and mathematical thinking (reasoning, problem solving). The identified episodes were then read more closely to name and classify different kinds of events.

Supporting Mathematical Events

As with the Anderson, Anderson and Shapiro (2004), we found a great deal of variation in the mathematical events engaged in by various parents and children. However, looking across all seven families, we did find some kinds of events in common across multiple families, including creating connections between the activity and other experiences, naming mathematical vocabulary and teaching content, and encouraging active participation.

Creating Connections

Several parents connected making the playdough to other experiences cooking and eating food. For example, when starting the activity, Harris's mother said, "You know how papa watches those chef shows and you see them measure stuff out and they do it like that?" Harris responded: "I'm on a chef show!" Both Harris and his mother returned to this idea during their time cooking and playing. This context not only connected the mathematical activity to a real world example, but also gave Harris's mother a way to emphasize the importance of making an exact measurement. In other families, mothers encouraged children to create various kinds of food, which created opportunities for children to engage in visualization and geometric reasoning, as they had to hold the image of the discussed food in their minds and then use the playdough to create a three-dimensional representation.

Naming Vocabulary and Teaching Content

All of the mothers and children engaged in mathematical events that required the children to count, and typically for a necessary purpose such as counting the drops of food coloring that needed to go into the playdough, rather than for a created context such as counting the number of objects made. Parents also used a variety of words related to shape, space, and measurement, including circle, square, longer, shorter, bigger, cup, half, tablespoon, and teaspoon. Some mothers seemed to make particular efforts to repeat words that may have been unfamiliar to their children. For example, when measuring the oil for the playdough, Steven's mother said: "Where is the teaspoon? We need one teaspoon of baby oil." And then, apparently after the oil was poured added, "This is one teaspoon of baby oil."

Beyond using mathematical vocabulary, several parents also made an effort to teach mathematical concepts to their children. Several parents carefully introduced the measuring cups and spoons to their children naming each one and asking children to point out which was needed.

Some parents also invited their children to think with them about how many scoops would be needed to create 2 teaspoons or about how to create a variety of shapes with the playdough.

Encouraging Active Participation

Most of the mothers worked to actively engage their child in the activity, whether through assigning tasks in the cooking, such as finding the ½ cup measure and filling it with salt, or by encouraging the children to extend or deepen their play. Mothers asked their children what else they could make or suggested ideas like "making shapes" or "an omelet." Some mothers also seemed to play with their children and their own creations offered new ideas to their children, and also opportunities for comparison. For example, Tasha said to a playmate "oh my mom made a flat pancake and I made a bigger pancake than that." And after Harris made two French fries his mom commented: "Those two fries are just hanging out by themselves. They look so lonely. They don't have no friends." This comment encouraged Harris to continue his engagement with the activity. He replied: "I am going to put a long one. A long one."

Discussion

Documented differences on early measures of mathematics achievement have led some to speculate that minority and low-income children may not be receiving mathematical support in homes. However, ethnographic studies have suggested that children may be receiving support, but that this support may not align with school mathematical practices. This study supports the later viewpoint and suggests that educators in designing early mathematics curricula and parent workshops could seek to build on the productive support already present in children's homes.

MATHEMATICAL SOCIALIZATION THROUGH GAME ACTIVITY: COMMON CORE STANDARDS FOR MATHEMATICAL PRACTICE IN AN AFTER-SCHOOL CLUB

Alexander Radosavljevic
University of Illinois at Chicago
arados2@uic.edu

Angela Thompson
Governors State University
athompson7@govst.edu

In this qualitative study, we examined the interactions and language tensions of three Spanish/English bilingual fourth graders and an adult facilitator in an after-school mathematics club as they played The Tower of Hanoi, a mathematical game. We mapped participants' actions to the Common Core State Standards for Mathematical Practice to identify the potential for mathematical socialization through game activities. We found that participants engaged in the following mathematical practices: breaking the problem into simpler versions; asking useful questions; communicating strategy with precision; evaluating peer solutions, explanations, and strategies; using counterexamples; and persistence in problem-solving.

Keywords: Elementary School Education, Informal Educational, Standards (broadly defined), Problem Solving

Introduction and Theoretical Perspective

This study provides research on the intersection of mathematics socialization with game activities that have not been sufficiently addressed in research. Although there is general agreement that children's mathematical content learning is enhanced through game activities, it is not clear how children engage with mathematical thinking and practice during game activities. This investigation provides a first step towards building an understanding of the possibilities for enhancing language minority children's development of mathematical thinking and practice through game activities.

We focused our analysis on video data of one group of four Spanish/English bilingual Mexican American females, three 4th graders and their undergraduate facilitator, as they engaged in a game activity based on the *Tower of Hanoi* (TOH). This vignette is part of a larger data set of video, field notes, interviews, and student artifacts captured over a four-year period during an after-school program. Educational activities were organized around playful mathematics enrichment activities in a bilingual atmosphere using games, puzzles, and projects in small groups and one-on-one interactions.

Our research question explores social aspects of cognitive processes in the transition from play activities to more abstract thinking. We ask, what is the value of game activities for socializing children in mathematical thinking and practice? Our study aims to uncover styles of interaction that contribute to the socialization of mathematical thinking and practice at a microgenetic level. The quote below gives background to the basis of our question, which is based on sociocultural (Vygostsky, 1987) and cultural historical activity theories (Leont'ev, 1981).

> Learning how to use a symbolic tool, play a game, deploy a strategy, carry out a complex intelligent action, and understand social and psychological functioning are cognitive attainments. These types of skills and understanding can only be obtained through social

> processes and are not available through solitary activity or introspection. The reason is that symbolic representations, like language, and cultural practices are social constructions; rules of play are social conventions; and modes of informal and formal learning by observing and interacting with others are social processes. Complex intelligent actions often entail preferred ways of doing things, which include behavioral sequences, symbolic and material tools, and a formulation and interpretation that reflect the language, values, and practices of the group. (Gauvain & Perez, 2007, p. 607)

Identifying and disaggregating the acts and actions participants use in pursuit of goals is a fundamental objective in analysis according to cultural historical activity theory.

There are three main reasons for our focus on mathematical practices as they are defined in the Common Core State Standards. First, there is a high demand for research that maps the Common Core State Standards to mathematics pedagogical practices and learning activities for classroom and out-of-school contexts. Second, the standards succinctly summarize principles of mathematical thinking and practice found in mathematics education research (Harel, 2008; Schoenfeld, 1992). Third, there is a need to explore and expand on the value of activities that counter traditional back-to-basics trends by uncovering alternate and effective routes to development and learning (Fisher, Hirsh-Pasek, & Golinkoff, 2012). It is important to note that we are not advocating for game activities to supplant classroom instruction. We view mathematical game activities as an important enrichment to mathematical learning and socialization.

Data and Methods

The participants in the vignette *What's the Point?* used a competitive participation style for playing TOH. The three children and facilitator were all bilingual Spanish/English speakers with varying degrees of proficiency in each language. All the children attended the same school where the after-school program took place. The after-school sessions occurred twice per week for 10 weeks of every school semester for 90 minutes in a classroom at the children's school.

The title of this vignette comes from one child's repeated use of the phrase, "What's the point?" Maritza, the author of this phrase, was the only one of three children who reached a successful solution. During the game set up sequence, Maritza demanded a more precise explanation of the game from Gabriela who introduced the game to the group. As time passed, the other two children gave up trying to solve TOH and Maritza occupied herself with another game. Thirty minutes later, the adult facilitator took up TOH, reached an impasse, and announced to Maritza that they should try another game. Instead, Maritza dropped her solitary game activity and announced that she would try TOH again. She reached a solution.

Two researchers independently viewed video data of a group playing *Tower of Hanoi* and coded for language tensions and mathematical thinking practices outlined in the Common Core Standards. Researchers resolved differences in coding through iterative viewing of the data in consultation with each other. Language tensions were used to index speech acts that were involved in processes of meaning making. Questions, negation, repair practices, etc. are some of the most common building blocks of mathematical thinking practices.

Results and Discussion

Children's explanations during game activities did not on the surface appear *mathematical* because they were focused on procedure, game rules, fairness, and strategies for winning.

However, their explanations did involve understanding relations among multiple strategies. Children also marked errors in their peers' strategies, providing opportunities for reconceptualizing problems contained in the game structures. They actively explored contradictions in solutions and pursued alternative strategies. Their collaborative activities involved individual accountability and though they managed to reach consensus on many occasions, they did not reference formal mathematical concepts. Considering that this after-school program was not created to be a remedial tutoring establishment or precisely aligned with this school's classroom mathematics curriculum, children's explanations during game activities were surprisingly *mathematical* when viewed with respect to the Common Core State Standards for Mathematical Thinking. We have mapped children's actions during game activity to mathematical thinking practices in Table 1 below. All quotes are from the video data.

Table 1: Summary of Mathematical Practice Coding References

Observed Activity	CCSSI Mathematical Practices
Adult labels student "expert" and asks her to explain the game.	Try to communicate precisely to others.
Student:"If she had done it another way..."	Evaluate peer solutions and reasoning.
Student challenges peer's explanation 7 times saying "What's the point?" & "I don't understand".	Evaluation of explanation.
Student restates explanation of game rules after being challenged.	Try to communicate precisely to others.
Adult asks question using game pieces and models incorrect procedure.	Modeling how to use counterexamples.
Student asks question using game pieces, "Can I do it this way?"	Recognize & use counterexamples.
Group uses only 6 out of 7 game pieces.	Break problem into simpler version.
Students interrupt another student's turn and move game pieces differently.	Evaluate peer solutions.
Student fails to solve problem 3 times but executes correct solution (31 minutes).	Persistence in problem solving.
Student asks "…you cannot move a pile like that?" while moving game pieces.	Ask useful questions and use counterexamples.
Student says "Let me practice!" & rehearses solution using game pieces.	Persistence in problem solving.

Persistence in problem solving and resilience to error correction from other participants are two factors that we believe are crucial for successful solutions in this case. Maritza, who demanded precise explanation from Gabriela and persisted in the face of contentious repair practices from her peers, appeared to thrive on challenge. Faced with occupying the role of passive observer, she retreated to her own choice of a different game and was content to play on her own. When she observed that the adult facilitator had given up on the challenging Tower of Hanoi game, she returned to the game and persevered to reach a successful solution while negotiating her peers' relentless repair practices.

Bandura (1993) reviewed four major processes influenced by students' perceived self-efficacy; cognition, motivation, affect, and selection. He outlined how students' belief in their self-efficacy to regulate their own learning determines their aspirations, level of motivation, and academic accomplishments. This may partially account for Maritza's persistence in solving the Tower of Hanoi. Maritza's motivation to defy the facilitator's suggestion to try another game may also be explained by her sense of self-efficacy, supported by the after-school environment which is responsive to children's needs and allows them to exercise their capabilities without restraint (Bandura, 1986).

Mathematical thinking practices are not easily measured or observed in informal contexts where activities are spontaneous and child-directed. These types of activities do not resemble formal or traditional classroom models and can be easily dismissed as having no value. However, we have found important components of social, emotional, and cognitive development in this informal after-school context. As a result of our study, we believe that there is a potential for amplification and reinforcement of mathematical thinking practices in game activities.

THE STRUCTURE OF MATHEMATICS MISCONCEPTIONS IN ALGEBRA, GEOMETRY RATIONAL NUMBER, AND PROBABILITY

Christopher Rakes
University of Maryland Baltimore County
rakes@umbc.edu

Robert N. Ronau
University of Louisville
bob@louisville.edu

The present study compared possible relationships between content area misconceptions in algebra, geometry, rational number, and probability to develop a conceptual framework of mathematics misconceptions. The sample consisted of 1,133 middle and high school students. We found that the explanations given by students for all tasks, regardless of the content area, were rooted in their understanding of five mathematical structures: absolute/relative comparisons, rational number meaning, additive/multiplicative units, variable meaning, and spatial reasoning. We therefore consider these five foundational structures to be critical for operationalizing mathematics understanding and developing understanding of more complex mathematical ideas. We also found that the notion that a particular misconception maps to a particular content area can often paint an incomplete picture of the misunderstandings that comprise a misconception.

Keywords: Algebra, Geometry, Rational Numbers, Probability

Researchers typically classify misconceptions by the content area in which the errors are observed. For example, Lamon (1999) considered misconceptions inherent to rational numbers while Watson and Shaughnessy (2004) focused on probability and statistics misconceptions; Kalchman and Koedinger (2005) studied algebra misconceptions; and, Clements and Battista (1992) examined geometry misconceptions.

The present study identifies links between student answers and explanations on mathematics problems to misconceptions in algebra, geometry, rational number, and probability. We also compared possible relationships between misconceptions in algebra, geometry, rational number, and probability. Our investigation was organized by two research questions:

1. What misconceptions are evident in students' explanations on algebra, geometry, rational number, and probability tasks?
2. What is the most valid representation of the relationship between misconceptions in algebra, geometry, rational numbers, and probability?

Literature Background and Theoretical Framework

Rational number misconceptions. Behr, Harel, Post, & Lesh (1992) found that difficulties with fractional meaning and equivalence lead to rational number misconceptions. Specifically, they suggested that such difficulties arise because students attempt to assign addition properties in situations when multiplication properties are required. Similarly, Steen (2007) described interpretation as a more fundamental problem for students than the computation of rational numbers.

Algebra misconceptions. Researchers have repeatedly found that the abstract nature of algebra increases its difficulty over arithmetic (e.g., Kieran, 1989). Specifically, abstractness poses an impediment that can be seen when students attempt to construct multiple representations of algebraic objects (Kieran, 1992). The primary abstract concept that confuses students in algebra is the meaning of variable (Kalchman & Koedinger, 2005), compounded by the multiple ways algebraic language is used (Kilpatrick, Swafford, & Findell, 2001).

Geometry misconceptions. Student orientation toward geometry is quite different from that of algebra: Students are often intrinsically motivated to study the properties that govern the shapes

encountered in daily life (Freudenthal, 1973). In spite of this motivational factor, students still struggle with errors and misunderstandings in geometry due to limited spatial reasoning (Clements & Battista, 1992).

Spatial reasoning begins with the differentiation between objects and representations. Objects are abstractions, ideas considered through reasoning (Battista, 2007). Representations, on the other hand, are used to signify objects other than themselves. For example, a line drawn on a piece of paper only represents a geometric line, defined in Euclidean geometry as having infinite length and no thickness.

Probability misconceptions. Probability misconceptions are tightly intertwined with algebra, geometry, and rational number misconceptions. For example, Freudenthal (1973) found that misconceptions that lead to difficulties with conditional probability arise from reliance on the representativeness heuristic, which in turn arises from over-reliance on linear proportions in algebra, geometry, and rational numbers. Falk (1992) noted that probability misconceptions such as representativeness and uniformity beliefs influence how students approach problem solving situations and misconceptions about probability distributions influence student understanding of non-linearity.

Methodology

Structural equation modeling was used to compare possible relationships between misconceptions in algebra, geometry, rational number, and probability. The present study was conducted with 1,133 students enrolled in 53 algebra or geometry middle and high school classes, taught by 17 mathematics teachers in three school districts. Because the sample is cross-sectional, causal inferences are not warranted. Conclusions are therefore limited to associations. An instrument was compiled for the present study from National Assessment of Educational Progress (NAEP) released items. All 17 items remained as given by NAEP; a prompt was included for each question asking students to explain how or why they chose their response, following the advice of Zawojewski and Shaughnessy (2000).

Data Analysis

To explore the nature of relationships between misconceptions in algebra, geometry, rational numbers, and probability, six structural equation models were compared (Figure 1).

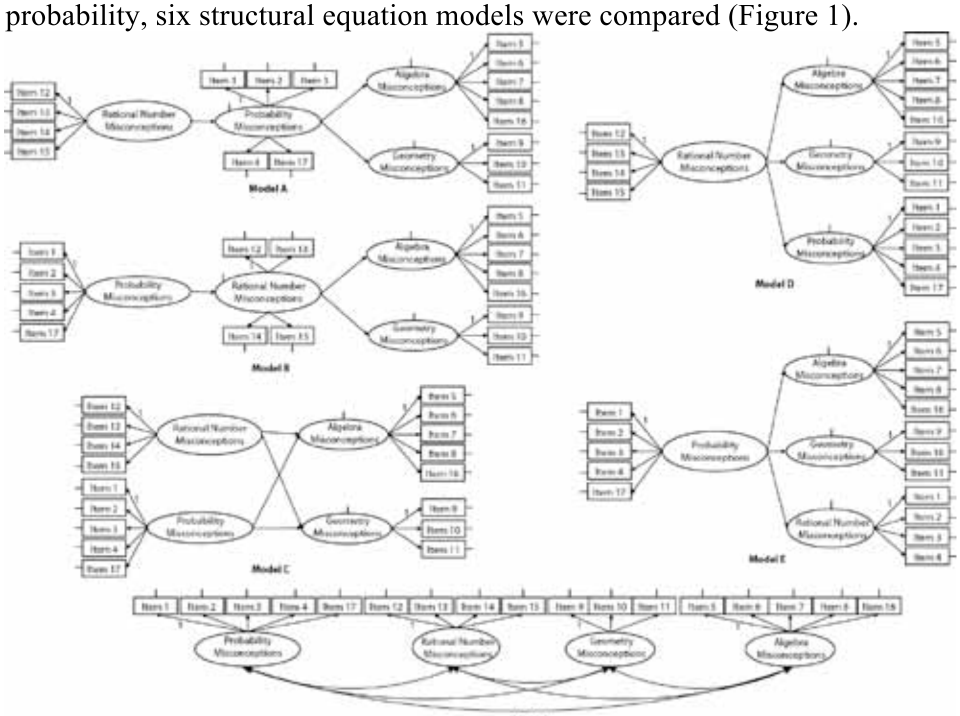

Figure 1: Six Structural Equation Models

Results

Comparisons of the six models in Figure 1 were based on the goodness of fit indices shown in Table 4. Error covariances were added based on modification indices and theoretical soundness. We based theoretical soundness on whether the same types of misconceptions were exhibited and/or the items measured the same content, with the misconception criterion taking priority. Additionally, the six data sets were randomly split into two data files each, one for calibration of the structural models and the other for validation of the resultant models to minimize the threat of over-fitting the model to the sample.

Table 4: Structural Equation Model Results

Model Description	DF	χ^2	CFI	RMSEA (90% CI)	SRMR	ECVI
Model A	**114**	**864.79**	**.98**	**0.032 (.022, .040)**	**.084**	**1.56**
Validation Model	114	764.63	.98	0.029 (.019, .038)	.077	1.34
Model B	**115**	**897.26**	**.97**	**0.035 (.026, .043)**	**.086**	**1.68**
Validation Model	115	763.73	.98	0.028 (.018, .037)	.076	1.33
Model C	**114**	**936.63**	**.97**	**0.039 (.031, .047)**	**.087**	**1.81**
Validation Model	114	745.12	.98	0.028 (.017, .037)	.076	1.31
Model D	**115**	**896.93**	**.97**	**0.035 (.026, .043)**	**.086**	**1.68**
Validation Model	115	757.73	.98	0.028 (.018, .037)	.076	1.33
Model E	**114**	**864.79**	**.98**	**0.032 (.022, .040)**	**.084**	**1.56**
Validation Model	114	764.63	.98	0.029 (.019, .038)	.077	1.34
Model F	**112**	**892.61**	**.97**	**0.036 (.027, .044)**	**.085**	**1.67**
Validation Model	112	742.57	.98	0.028 (.018, .038)	.076	1.32

Note. For the sake of space, only the final exploratory and validation models are shown.

All six models fit very well, based on benchmark criteria defined by Byrne (1998). No model fit better than the others.

Discussion

We found that the amount of overlap in students' misconceptions across content areas resulted in a high degree of multicollinearity, so we concluded that the best among the hypothesized models was Model F (see Figure 1), which modeled content area misconception factors as covarying at a single level. We concluded, however, that none of the hypothesized models represented the observed patterns of misconceptions well, primarily because none of them accounted for the observed overlap across content areas. We believe, therefore, that mathematics misconceptions are more complex than

the models indicated by previous research and that future research should investigate more complex models of misconceptions. For example, misunderstandings about the five foundational structures seemed to be at the heart of student explanations that indicated misconceptions. We therefore consider these five foundational structures to be critical for operationalizing mathematics understanding and developing understanding of more complex mathematical ideas.

THE IMPACT OF SPATIAL ABILITY AND PREFERENCE ON PERFORMANCE IN SINGLE VARIABLE INTEGRAL CALCULUS

Rebecca Schmitz

Michael N. Johnson
Michigan Technological University
mnjohnso@mtu.edu

The present study examines the relationships between preferred mode of thinking (analytical or graphical), spatial reasoning ability, ability to use graphical reasoning on calculus tasks, and performance in single-variable integral calculus. Data was collected from eight students. The results suggest that there may be correlations between these spatial reasoning ability and performance, preferred mode of thinking and spatial reasoning ability, as well as preferred mode of thinking and ability to use graphical reasoning on calculus tasks.

Keywords: Post-Secondary Education, Geometry and Geometrical and Spatial Thinking, Advanced Mathematical Thinking

Background

Researchers have long attempted to identify various factors that influence success in calculus. Recently, Ubuz (2011) considered factors of gender, age, major and prior achievement on success in second semester calculus and found that both gender and prior achievement impacted success. Others have considered students' preference for the use of different types of reasoning when solving calculus tasks and have found that students prefer analytical reasoning to graphical reasoning on certain integral tasks (e.g., Comacho & González-Martín, 2002; Sevimli & Delice, 2011). Following Presmeg (1985), Suwarsono (1982), and others, we believe that a student's preference for using graphical reasoning on mathematical tasks falls on a spectrum, from strongly preferring graphical reasoning to strongly preferring analytical reasoning. Combining measures of preference and performance, Haciomeroglu and Chicken (2011) looked at the relationship between performance on the AP Calculus exam, spatial ability, and preference for using graphical reasoning, and found that spatial visualization is strongly correlated to performance on the AP Calculus exam, as is preference for using graphical reasoning on calculus tasks. Differential calculus, with content parallel to AP Calculus, contains a mixture of analytic and graphical topics; the same is true of integral calculus, although one can argue that a larger portion of the content is abstract in nature (e.g., sequences and series). We are not aware of any studies that consider preference for using graphical reasoning, spatial reasoning ability, and performance in integral calculus. Are trends similar to those found by Haciomeroglu and Chicken (2011) also present when considering integral calculus students?

The goal of the present study was to examine the relationships between preferred mode of thinking (analytical or graphical), level of spatial reasoning ability, ability to use graphical reasoning when solving calculus tasks, and performance in integral calculus.

Methods

Participants

The participants were 8 undergraduate engineering students enrolled in integral calculus at a small Midwestern university. The average age at the beginning of the study was 19.1 years, with the students ranging in age from 18 to 21. The students had no integral calculus experience prior to participation in the study and were chosen from a single instructor's sections, with the

exception of one student who was added late as a replacement.

Materials and Procedure

The students met with the first author 10 times over the course of the semester. In four of the sessions, students individually completed pencil and paper assessments including measures of spatial reasoning ability and preference for using spatial reasoning. To assess preference for using spatial reasoning, students were given the Mathematical Processing Instrument for Calculus (MPIC) (Haciomeroglu & Chicken, 2011). The MPIC consists of two parts: a set of mathematical tasks and a questionnaire. The graph of a function or the equation for a function is presented and students are asked to draw the graph of either the derivative or an antiderivative. The questionnaire presents possible graphical and analytic methods of solution to each task and the student selects the solution that most closely matches their method of solution. The MPIC consists of 20 tasks, split evenly between derivatives and antiderivatives. In scoring the MPIC, students received 2 points for using a graphical solution, 0 points for an analytic solution, and 1 point if it was a mixed solution, for a total of 40 possible points (MPIC-Graph). In addition, each task was scored as correct or incorrect, for 1 or 0 points respectively, with a total of 20 possible points (MPIC-Perf). Both scores are included in Table 1.

To assess a student's level of spatial reasoning ability, four tests from the Kit of Factor-Referenced Cognitive Tests (Ekstrom, French, & Harman, 1976) were given: cube comparisons (CC), card rotations (CR), paper folding (PF), and form board (FB). These tests measure spatial orientation (CC and CR) and spatial visualization (PF and FB). Since we lack a larger population to compare these scores to, we used the means and standard deviations from Kozhevnikov, Motes, and Hegarty's (2002) study with 60 undergraduate students to compute z-scores for each of our students. Following them, we averaged the z-scores for each of the four tests to get a spatial reasoning score (SpReas). This enabled us to label students as having relatively high, medium, or low level of spatial reasoning abilities. Engineering students typically have a higher level of spatial reasoning so it was no surprise that most of our students scored above the mean.

Scored copies of the midterm and final exams were also collected. A weighted exam score was computed according to the course rubric (15% for each of the three midterms and 25% for the final exam) and a z-score was computed to compare the students' performance with the 101 total students in the class. The z-scores are recorded in Table 1.

In the remaining six sessions, the students worked in pairs to complete a series of routine and non-routine mathematical tasks centered on limits, definite integrals and approximation, improper integrals, and infinite series. Although the limit concept is differential calculus content, we included it so that connections might be made between a student's understanding of the integral calculus topics and their understanding of the limit concept. Non-routine tasks included finding connections between an infinite series and the related improper integral, for instance, $1+\frac{1}{2}+\frac{1}{4}+\frac{1}{8}+\ldots$ and $\int_0^\infty \frac{1}{2^x}dx$ or $1+\frac{1}{2}+\frac{1}{3}+\frac{1}{4}+\ldots$ and $\int_1^\infty \frac{1}{x}dx$. Students were paired based on performance on their first midterm exam, with the following pairings: students A and G; B and D; C and F; and E and H. Students were paired based upon performance on the first midterm exam. Each session was videotaped and coded for use of graphical reasoning as "Correct and helpful reasoning from graph" (CH); "Correct but unhelpful reasoning from graph"; "Incorrect reasoning with graph"; and "Unable to reason with graph." We summed the tallies from the last three codes to obtain an Incorrect Reasoning Summary (IR-Sum) score. We included the "Correct but unhelpful reasoning from graph" in this even though the reasoning was correct, it was not applied in an appropriate context and did not lead to a correct solution. Both the CH and

IR-Sum are recorded in Table 1. Because students were interviewed in pairs, the reasoning was tagged as coming from either student X, student Y, or both students X and Y. The authors independently coded a subset of the videos, discussed any discrepancies, and recoded until agreement was above 90%.

Results and Discussion

Each student's level of preference for using graphical reasoning when solving calculus tasks, as measured by the MPIC, is recorded in Table 1 (MPIC-Graph). We categorized two students as having a high level of preference for using graphical reasoning: students A and D; four students as having a medium level of preference: students B, C, E, and G; and two students as having a low level of preference: students F and H. Performance on the MPIC (MPIC-Perf) also varied, with three of the students performing at a very low level. The general low performance on this assessment was surprising since the graphs of derivatives and antiderivatives are differential calculus material, and we hypothesize that it is due to the amount of time since students have used these skills. The students in the study took differential semester calculus in the prior academic year and this assessment was given approximately four weeks into the fall semester.

We noticed students with lower performance on the MPIC-Graph tended to have lower levels of spatial reasoning. To investigate this further, we computed the Pearson Correlation and got a non-significant correlation (r=.535, ρ=.171). Student F is an exception to this trend and when we recomputed the Pearson Correlation after removing Student F, we got a significant correlation (r=.789, ρ=.035). We are currently extending this study with a group of 12 additional students and we hope to confirm this relationship with a larger population. Student F can be characterized as a high-ability student who is capable of using graphical reasoning, but prefers to use the more efficient analytical thinking on the derivative and antiderivative tasks. When solving tasks in interviews that required the use of graphical thinking, Student F showed an efficient use of graphics and often used only a sketch or even a portion of a sketch to gain the necessary information. This is in contrast with students like Student E and Student H who painstakingly created detailed graphs and often lost track of the goal of the task.

Another trend we noted was that students with a higher level of spatial reasoning ability (SpReas) tended to perform better on the exams (as measured by the Exams z-score). There again was not a significant correlation when we computed the Pearson Correlation (r=.437, ρ=.280), but when we removed Student B and recomputed, we got an almost significant correlation (r=.752, ρ=.051). Student B performed above the mean on the exams and had a relatively lower level of spatial reasoning ability and a higher level of incorrect reasoning on the interview tasks. The high level of incorrect reasoning on the interview tasks can be attributed to this student's reluctance to say $\lim_{x\to a} f(x) = L$ unless $L = f(a)$ (instead saying $\lim_{x\to a} f(x) \approx L$). We plan to investigate this trend further once we have a larger data pool. In particular, we would like to compare performances on the analytical versus the graphical problems on the midterm and final exams with spatial and logical reasoning abilities.

A third trend we noticed was that students with a relatively lower level of spatial reasoning (SpReas) tended to have higher IR-Sum scores. Again, this is not a perfect trend and may be impacted by the interview pairings as the scores for group answers apply to both students. When we computed the Pearson Correlation for the IR-Sum with the group answers and the IR-sum without, we had a significant correlation between the two (r=.884, ρ=.008). We found no significant correlation between these two factors (SpReas and IR-Sum) (r= -.534, ρ=.172), but, as before, we have one student who is an outlier, Student E, and if we remove that student, we do

have a significant correlation (r= -.786, ρ=.036).

In conclusion, we believe the trends that we have noted here warrant further investigation: if confirmed with a larger data pool that performance is correlated to spatial reasoning ability, this would have direct implications for instruction. While we have no evidence yet that spatial reasoning ability impacts performance on non-spatially loaded mathematical tasks, such results have been found in chemistry (Carter, LaRussa, Bodner, 1987). Furthermore, if we confirmed the correlation between spatial reasoning ability and preference from the MPIC, we can help establish the validity of using the MPIC as a tool for assessing integral calculus students' preference for using graphical reasoning.

Table 1: Performance on Measurements of Ability and Preference

	Student A	Student B	Student C	Student D	Student E	Student F	Student G	Student H
Preference:								
MPIC-Graph (40)	26	12	19	28	16	4	16	1
MPIC-Perf (20)	16	3	16	11	11	10	4	4
Ability (z-scores):								
Exams	0.94	1.16	1.18	-0.01	-1.12	1.42	0.91	-1.95
SpReas	0.73	0.04	1.16	0.96	0.88	0.98	0.85	-0.06
Reasoning in interview tasks:								
CH	29	19	33	36	30	27	23	25
IR-sum	7	17	4	5	20	4	15	14

STUDENTS' MATHEMATICAL BEHAVIORS FOLLOWING INSTANCES OF MATHEMATICAL CONFLICT: AFFECTIVE/SOCIAL INFLUENCES

Evelyn Seeve
Daemen College
evelynseeve@gmail.com

Distinguishing viable arguments from those which are flawed is a critical skill for mathematics learners, and especially for those participating in collaborative learning environments. When students encounter mathematical ideas that conflict with their own perspectives during group problem solving, affective/social interactions may be key in shaping their mathematical responses. Through analysis of two cases, this paper highlights several affective/social considerations, such as students' personalities, classroom context of the mathematical conflict, and mathematics ability of those engaged in the conflict, which may interact to influence students' mathematical behaviors when their incorrect ideas are challenged by their peers during collaborative mathematical problem solving.

Keywords: Problem Solving; Affect, Emotion, Beliefs, and Attitudes; Middle School Education

Theoretical Framework/Purpose of Study

Mathematics goals for elementary and middle school students emphasize the importance of students' developing skills not only in constructing valid mathematical arguments, but also in "critiquing the reasoning of others" (Common Core State Standards Initiative, 2010). In order to evaluate others' reasoning, students must be able to consider another's mathematical perspective. Research, however, has demonstrated difficulty students may have in understanding others' mathematical reasoning, and especially in adopting others' mathematical view points. Students' resistance to accepting others' mathematical perspectives may be due to a lack of relevance or meaningfulness of others' ideas and the need to be actively interested and engaged in order to completely integrate others' ideas into one's own schemata (Maher & Martino, 2000). Research has highlighted complex ways in which affect may interact with students' cognitive processing in general (Schutz & Pekrun, 2007) and specifically in influencing students' mathematical thinking (Goldin, 2002; Ma, 1999; McLeod, 1994). When students are involved in collaborative mathematical problem solving activities, affective and social issues may become more salient. In particular, when students' ideas are challenged by peers, students' emotions can be critical in understanding their mathematical behaviors (Goldin, Epstein, Schorr, & Warner, 2011). This research examines two cases, both involving urban middle school students working collaboratively on the same task in different classrooms, in which students' incorrect mathematical ideas are challenged by peers. The two students' subsequent mathematical behaviors are then analyzed and compared in light of the social and affective classroom context.

Research Questions and Methodology

The questions that framed this research study were: 1) What types of mathematical behaviors do middle school students demonstrate when their ideas are challenged by peers during collaborative mathematical problem solving? 2) How may affective or social classroom contexts influence the students' mathematical behaviors during those instances?

Data for this study included videotapes collected from classrooms of two middle school mathematics teachers, Ms. B. and Ms. S., in one large urban district. These teachers were selected for a broader research project based on their participation in professional development aimed at helping teachers create emotionally safe classroom environments (Schorr, Warner, Gearhart, & Samuels, 2007). During classroom sessions for both teachers, students worked on the same mathematics task in groups of 3-4 students, spanning two class sessions for Ms. B. and three class sessions for Ms. S. Ms. B. considered her class to be a high ability group, while Ms. S. considered her students to be of low mathematics ability. The students worked on a problem adapted from a task entitled *Building Blocks Dilemma*. A worksheet distributed to the students contained the following diagram:

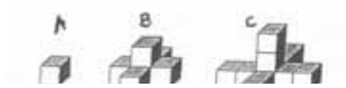

Figure 1: Building Blocks Task Diagram

Students were asked to find the number of cubes needed to build a 5-block high tower and a 10-block high tower and to generalize how many blocks would be needed for any size tower. The task was selected for use in the larger study because of its potential for high cognitive demand (Stein, Smith, Hennigsen, & Silver, 2000) and was designed to help students learn to make connections between patterns and equations. During the sessions interlocking snap cubes were available to students who wished to model the problem. The general solution preferred by students in the episodes investigated here involved noticing that each of the four branches in every tower of height n has one block less than the blocks in the height, leading to the solution method of multiplying 4 by n-1 to obtain the total number of side blocks and then adding n, the number of blocks in the tower's height.

Episodes involving students' mathematics difficulty were selected from the class sessions described above for analysis in a broader study (Seeve, 2012). These episodes were transcribed using audio and video data, and qualitative descriptions of the students' behaviors relating to the students' mathematical engagement following the instances were recorded, including descriptions of students' behaviors relating to their mathematical thinking, emotional feelings, and social interactions. Two episodes which involved students encountering mathematical ideas from peers that conflicted with their own ideas were selected for qualitative analysis here.

Results

Case 1: Marcos

Case 1 involves Marcos, a Latino student in Ms. B.'s class who appears even-tempered, self-assured, and sociable. On the first day of their work on the Building Blocks task, Marcos and his groupmates Lashanna and Larent have found correct solutions for towers up to 10- blocks high. Case 1 begins on Day 2 of the students' work, when Marcos proposes an incorrect solution of 460 blocks for the 100-block high tower.

When Ms. B. asks Marcos how he got his solution of 460 blocks, Marcos says he multiplied the number of blocks in a 10- block high tower, 46, by 10. Ms. B. suggests Marcos convince Lashanna of his solution and then walks away from the group. Lashanna tells Marcos that she got 496 as her solution for the 100- block high tower. Marcos keeps repeating his solution of 460 blocks. While Marcos speaks, he plays with his transparency. Lashanna explains that she got 500

and took away 4, one for each branch of the tower. While Lashanna speaks, Marcos continues playing with the transparency. He says, “it’s not 500” but does not address Lashanna’s justification for her solution. He continues playing with items on his desk and sings and whistles.

Lashanna later provides another explanation to Marcos for her solution, stating that since the 10-block high tower has 10 blocks in the height and 9 blocks in each of its branches, the 100-block high tower will have 100 blocks in the height and 99 blocks in each branch. When Lashanna asks Marcos to explain his method, Marcos simply repeats his earlier, incorrect reasoning. Again, he does not address Lashanna’s justification. Ms. B. suggests Marcos test Lashanna’s method by having Lashanna find the total number of blocks, using her method, for a tower Marcos already solved. Marcos asks Lashanna to solve the tower of height 5, for which he previously found a solution of 21 blocks.

Ms. B.: Let’s see. *(to Marcos)* What do you think?

Marcos: (puts his hands up.) I think…I think she probably won *(smiles)*.

Ms. B.: So you think she will? *(to Lashanna)* Ok, so now, can you walk us through your process again?

Lashanna: Eh…this is 5 *(pointing to the height in her tower)*…so in these 4 *(pointing to the tower’s branches)…*so 4 times 4 is 16, and then you just add the 5, and it would get you 21.

Marcos: (smiles at Lashanna) So you were right. *(to Ms. B.)* The same thing *(smiles)*.

Analysis, Case 1. This event occurs in a small group setting and involves Marcos, who presents confidence in his mathematics ability and works in a group with others who appear to be of similar ability. In this episode, Marcos continuously rejects Lashanna’s correct solution. He does not appear to consider her reasoning and simply keeps repeating his own solution, until Ms. B. engages him in a process of determining whether Lashanna’s solution is correct. Marcos then concedes, acknowledging that Lashanna’s, and not his own, solution method is correct. Marcos’s concession does not reflect embarrassment or loss of face.

Case 2: Leo

Leo, a reticent African American student in Ms. S.’s class who appears to have difficulty with mathematics, works on the Building Blocks task with groupmates Ordena and Ta’keisha. Ta’keisha is assertive, demonstrates stronger mathematics skills, and often dominates during the group members’ conversations. On Day 2 of the group members’ work on the Building Blocks task, the students in Leo’s group disagree on the number of blocks in a 100-block high tower. Ta’keisha arrived at a correct solution of 496 blocks by multiplying 4 by 99 (for the 4 branches) and adding 100 (for the height). Leo believes there would be 100, not 99, blocks in each of the four branches of the tower. Ta’keisha explains her method to Leo, but Leo still does not agree. Ms. S. suggests the students present both methods to the class during their presentation on Day 3.

During the group’s presentation, Ta’keisha tells the class that she obtained a solution of 496 cubes for the 100-block high tower. Leo comments, “So I disagreed with her because why is it 99 on each side, not 100?” At Ms. S.’s suggestion, Ta’keisha justifies her solution:

Ta’keisha: On this paper for example, A is only one block and it’s one cube. And then for the B, it’s a 2- block high tower...It’s only one going on each side...And then for C…it’s a 3-block high tower but you only see two. So it’s 2 on each side.

Ta’keisha continues, “You know how you don’t see the middle cube? I’m saying the amount that you see is the amount on each side.” During the remainder of the group’s presentation, Leo is quiet. Towards the end of the presentation, Ms. S. asks the class if the 5-block high tower Ta’keisha has built, with 5 blocks in the height and 4 blocks in each branch, is a valid tower. Most, but not all, students agree that it is a valid tower. When the students in Leo’s

group return to their seats following their presentation, Leo says to Ta'keisha, "See, I was right. See, ha."

Analysis, Case 2. Leo demonstrates a reserved nature and is of weak mathematics ability. He works in a group with Ta'keisha, who is assertive and of significantly stronger mathematics ability. On Day 3, Leo's disagreement with Ta'keisha occurs in the context of the full class. During the group's presentation, Leo appears to recognize that Ta'keisha's solution method, and not his own, is correct. Leo, nevertheless, seems to hold on to his own original idea in order to save face in front of his classmates. Leo's comment to Ta'keisha at the conclusion of his group's presentation indicates feelings of inferiority.

Cross-Analysis, Cases 1 and 2. In both cases analyzed here, students initially resisted adopting their peers' correct mathematical viewpoints which conflicted with their own incorrect mathematical ideas. In Case 1, Marcos eventually expressed agreement with Lashanna's solution without indication of embarrassment. Leo in Case 2, however, in an apparent attempt at avoidance of loss of face before his classmates, does not express agreement with Ta'keisha's method, even though he apparently begins to recognize his solution is not correct.

Discussion/Conclusions

Cases 1 and 2 support evidence found in earlier research regarding students' resistance to adopt mathematical perspectives of their peers. The cases examined here further demonstrate affective and social classroom contexts that may influence whether, and how, students modify their mathematical thinking to accept ideas proposed by their peers when those perspectives conflict with their own. Considerations include personalities of students engaged in the mathematics conflict, mathematics ability of those students, and whole class vs. small group context of the conflict. Limitations of the study include the small sample size and the inference of students' emotions from their observable behaviors on videotape. Results of the analysis have implications for mathematics education practitioners and researchers interested in maximizing opportunities for students to advance their mathematical knowledge by considering conflicting perspectives posed by their peers.

THE DIRECT AND INDIRECT EFFECTS OF SELF-EFFICACY BELIEFS AND SELF-REGULATED LEARNING STRATEGIES ON MATHEMATICAL MODELING

Anu Sharma
University of Florida
anusharma@ufl.edu

In this study, associations were examined between self-efficacy beliefs, self-regulated learning strategies, and students' performance on the modeling tasks. In all, 225 eighth- and ninth-grade students from a local research developmental school reported on a modeling self-efficacy scale, a modified version of the MSLQ, and a modeling test. The modeling self-efficacy scale has been developed and pilot tested, and the modeling problems were adapted from the PISA 2003 problem-solving assessment. The relationships between the variables were depicted in the form of a statistical model, which was tested using structural equation modeling techniques. The model fits the data reasonably well with self-efficacy plays a significant role in predicting students' performance on the modeling tasks. The correlations between cognitive strategies, metacognitive strategies, and modeling task success were not significantly different from zero.

Keywords: Beliefs, Cognition, Metacognition, Modeling

Introduction

Mathematics education currently emphasizes engaging students in mathematical modeling to prepare them for 21st century global workforce (CCSSO, 2010; English & Sriraman, 2010; Lesh & Zawojewski, 2007). Modeling with mathematics is the process of using knowledge and skills from across and within the curriculum to solve problems arising in everyday life, society, and workforce (CCSSO, 2010). The purpose of the present study was to investigate factors that may influence students' modeling outcomes. Due to a lack of literature informing which contextual factors impact students' success in solving real-world tasks, the study drew upon problem-solving literature to explore the degree to which effective problem-solving behaviors are associated with students' modeling outcomes.

Researchers have asserted that effective problem-solving behaviors such as setting appropriate goals, controlling one's actions, monitoring one's progress, trying alternative solution paths, and perseverance with challenging academic tasks align very closely with self-regulated learning (SRL) behaviors (Pape & Smith, 2002; Zimmerman & Campillo, 2003). Self-regulated students control and regulate their thoughts, actions, behaviors, and motivation in order to achieve a targeted goal. In the field of mathematical problem solving, self-efficacy beliefs and SRL strategy use profoundly influence students' engagement and persistence on complex mathematical tasks (De Corte, Verschaffel, & Op't Eynde, 2000; Pintrich & De Groot, 1990). The present study built upon and extended past literature by examining these associations in the context of mathematical modeling and real-life problem solving.

Theoretical Framework

Social cognitive theory is a useful framework for understanding SRL behaviors that enhance students' problem-solving skills (Zimmerman & Campillo, 2003). The theory states that proactive, self-reflecting, and self-regulated learners have the capacity to take control of their thoughts, feelings, and actions. According to Bandura (1997), people display this sense of personal agency because of the beliefs they hold about themselves and their capabilities. Such

self-beliefs, which represent individuals' perceived confidence to accomplish goals, are called self-efficacy beliefs. In academic settings, particularly school mathematics, self-efficacy refers to students' judgments of their abilities to solve mathematics problems, perform mathematics-related tasks, or engage in mathematical activities (Pajares, 1996). Self-efficacy beliefs are task- and situation-specific judgments, which are reported in relation to a goal. These beliefs reflect students' judgments of performing a task in future rather than their actual performance level. In actual reporting, students may underestimate or overestimate their judgments about their own competence (Pajares & Miller, 1994; Schunk & Pajares, 2009). Much research shows that self-efficacy beliefs correlate positively with students' problem-solving achievement (Pajares & Miller, 1994, Pintrich & DeGroot, 1990). These studies provide evidence that students' beliefs about their competence are a significant predictor of their problem-solving or academic performance even after controlling for mental ability and mathematics anxiety.

In addition to self-efficacy, SRL students control their cognition by employing several learning strategies. The present study focused specifically on the use of cognitive and metacognitive strategies. Cognitive strategies are learning strategies that influence students' processing of information, for example elaboration, organization, and critical thinking (Pintrich & De Groot, 1990; Pintrich et al., 1991). Elaboration strategies, such as paraphrasing, summarizing, and note taking, support students' acquisition of information by integrating new material with existing knowledge. Organizational strategies help students in building connections between different ideas and in arranging the material meaningfully. Finally, critical thinking strategies support students to make logical decisions. Metacognitive strategies are typically comprised of three different types of knowledge including planning goals, monitoring actions, and regulating strategies or methods. Planning strategies assist students in analyzing the task and setting appropriate goals. Monitoring strategies focus students' attention on the task and prompt them to keep track of their strategies and actions. Regulating strategies help students to improve their problem-solving skills by modifying strategies or methods of inquiry, acquiring more information or reviewing previous material.

Similar to academic self-efficacy, cognitive and metacognitive strategies directly influence students' problem-solving achievement (Pintrich & De Groot, 1990; Zimmerman & Martinez-Pons, 1988). These studies found that students who report using more cognitive and metacognitive strategies solved more mathematics problems correctly and received higher grades. Further, Pintrich and De Groot reported that students who believe in their abilities are more cognitively engaged as well as display greater use of cognitive and metacognitive strategies in solving mathematics problems. Other studies also confirmed that self-efficacy influence achievement directly as well indirectly through personal goal setting (Zimmerman & Bandura, 1994) or monitoring academic tasks (Bouffard-Bouchard, Parent, & Larivee, 1991).

Given the literature in the field, three research questions were investigated: (a) what are the direct effects of modeling self-efficacy beliefs on students' performance on modeling tasks? (b) What are the direct effects of students' use of cognitive and metacognitive strategies on their performance on modeling tasks? (c) What are the indirect effects of students' self-efficacy beliefs for modeling tasks on their performance on modeling tasks through its effects on their use of cognitive and metacognitive strategies?

Method

Participants

The current study recruited 225 eighth- (n = 88, 39.11%) and ninth-grade (n = 137, 60.8%) students from a local research developmental school affiliated with the researcher's university. The average age of the participants was 14.22 with a standard deviation of 0.85. Participants reported their ethnicity as White (n = 111, 49.3%), African American (n = 46, 20.44%), Hispanic (n = 33, 14.6%), Asian (n = 12, 5.33%), and Native Hawaiian (n = 1, 0.44%). The remaining students reflected their ethnic background as either a combination of these categories (n = 19, 8.4%) or as "others" (n = 3, 1.33%).

Measures

Three instruments were used to measure the desired constructs including: (i) a self-efficacy scale that has been developed and pilot tested to measure students' efficacy judgments on the modeling tasks, (ii) a modified version of the Motivated Strategies for Learning Questionnaire (MSLQ) as developed for *Connected Classroom in Promoting Mathematics* (CCMS) project to assess students' use of cognitive and metacognitive strategies, and (iii) a modeling test adapted from PISA 2003 problem-solving items to measure students' modeling competencies.

Results

The hypothesized relationships were estimated using Mplus statistical software. The measurement model provided an adequate fit to the data ($\chi 2$ [390 df, N = 225] = 595.97, p = 0.00, CFI = .94, TLI = .94, RMSEA = .048 (with 90% CI lower bound= 0.041 and upper bound= 0.056). The full structural model also fits adequately to the given data with regard to CFI, TLI, and RMSEA fit indices ($\chi 2$ [390 df, N = 225] = 595.97, p= 0.00, CFI = .95, TLI = .94, RMSEA = .048 (with 90% CI lower bound = .041 and upper bound = .056)). Perceived modeling self-efficacy (β = .50, p = .000) directly positively predicted students' performance in solving modeling problems correctly. In other words, students who reported greater self-efficacy for solving modeling tasks were more likely to correctly solve modeling problems. On the contrary, organization strategy use ($\beta = -.62$, p = .004) had a significant negative direct effect on students' performance on modeling test. This means that students who reported using more organization strategies tended to get lower scores on the modeling test. Further, direct effects of students' use of critical thinking ($\beta = -.59$, p = .08), elaboration (β = .40, p = .41), and metacognitive strategies (β = .46, p = .16) on their performance in solving modeling tasks were non-significant. As such, the data did not provide any evidence of the direct effects of critical thinking, elaboration, and metacognitive strategies on their performance in modeling test. As expected, the indirect effects of students' self-efficacy for modeling on their performance in solving modeling tasks through its effect on their use of critical thinking ($\beta = -.225$, p = .10), organization ($\beta = -.006$, p = .91), elaboration (β = .128, p = .41), and metacognition strategies (β = .15, p = .18) were non-significant.

Discussion

The present study provided evidence that self-efficacy is an important factor impacting students' performance in solving modeling tasks. Therefore, teachers should build or improve their students' self-efficacy beliefs for solving complex modeling problems by providing them with vicarious learning experiences, effective feedback, and engaging them in self-evaluative processes. Furthermore, creating positive and supportive learning environments such as encouraging students to participate in classroom discussions, explaining their thought processes, and focusing on the process rather than the correct answer may positively impact students' self-efficacy beliefs.

The structural model of the study, however, did not provide enough evidence to support that use of elaboration, critical thinking, and metacognitive strategies was directly associated with students' modeling outcomes. One of the possible explanations for finding results inconsistent with the past literature would be that participating students might not be aware of cognitive and metacognitive strategies they used during mathematical learning and problem solving activities in school. Data also indicated that students who had successfully solved modeling problems rated themselves low on the use of cognitive and metacognitive strategies, and students who were unable to solve modeling problems correctly had both under- and over-estimated their use of strategies on the MSLQ scale. The low reliability estimate ($\alpha = .61$) of the organization scale further indicated that items on the scale were not measuring the required construct. Further, the modeling test included problems occurring in one's personal life, work and leisure, and in the community and society. As such, performance on the modeling test might be influenced by students' individual differences in reading, cognitive ability, their familiarity with the context of the problem, socioeconomic status, gender, and their prior mathematics achievement. The present study did not control for the influence of these factors on students' modeling achievement.

Given the findings of this study, it is possible the MSLQ might not be the best choice. Probably, a scale that specifically measures students' use of cognitive and metacognitive strategies in relation to real-world problem solving would be more appropriate. Therefore, for future studies mathematics researchers might consider modifying items on the MSLQ scale to align more with the strategies used by students when engaged in modeling kind activities. Furthermore, students' responses on the modeling test were scored in accordance with the rubric used by PISA 2003 problem-solving assessment. The PISA scoring guide might be conservative because it didn't give students partial credit for correctly solving many of the sub-questions or performing many of the mathematical steps. Thus, future investigation might include developing a more comprehensive scoring rubric for scoring students' responses on the modeling test.

UNDERSTANDING STUDENTS' ATTITUDES TOWARDS AND PERCEPTIONS OF HOMEWORK JOURNALS

Alexis Stevens
James Madison University
stevenal@jmu.edu

Jesse L.M. Wilkins
Virginia Tech
wilkins@vt.edu

Writing in mathematics has become increasingly more common in mathematics classes of all age levels. The purpose of this study is to explore and describe students' attitudes towards and perceptions of homework journals, a specific type of writing in mathematics. Students enrolled in a college mathematics course were interviewed about their attitudes towards and perceptions of writing in mathematics. Based on the analysis of this data, students were found to have both positive and negative opinions of homework journals, such as liking instructor feedback from the homework journals and disliking the open-ended nature of the homework journals. In addition, homework journals were found to be a valid mathematics writing task consistent with the current research literature on designing meaningful writing tasks.

Keywords: Affect, Emotion, Beliefs, and Attitudes; Instructional activities and practices; Post-Secondary Education

Purpose of the Study

Mathematical writing can challenge students to purposefully reflect on their learning (Borasi & Rose, 1989), to think critically about mathematical ideas (Emig, 1977), and to deepen their mathematical understandings (Hamdan, 2005). While writing in mathematics can serve as a powerful tool, students' perspectives on mathematical thinking and learning through writing in mathematics are not well documented. The purpose of this study is to fill this gap in the research literature by exploring and describing students' attitudes towards and perceptions of homework journals, a specific type of writing in mathematics. Specifically, we will investigate the following research question: What are students' likes and dislikes associated with homework journals?

Theoretical Framework

Writing in Mathematics

Based on the current literature related to journal writing in mathematics, there are three important characteristics of journal writing assignments in mathematics: 1) prompts (Borasi & Rose, 1989), 2) clear expectations (Hamdan, 2005; Powell & Ramnauth, 1992), and 3) responses of the teacher (Borasi & Rose, 1989).

The first important characteristic of journal writing tasks, which is common among almost all of the examples in the current literature, is the prompt. The prompt can be relatively generic (Borasi & Rose, 1989) or extremely specific (Jurdak & Zein, 1998). The prompt can also be affective or cognitive (Jurdak & Zein, 1998). Regardless of their format, prompts are a critical element of journal writing.

Another important characteristic of journal writing tasks is well-communicated expectations. Teachers may communicate expectations in a variety of ways (Hamdan, 2005; Powell & Ramnauth, 1992). However expectations are communicated, it is valuable for both teachers and students to know what the teacher is anticipating from the journal responses in order for the journal writing to be meaningful to both teachers and students.

A third important characteristic of journal writing tasks is the response of the teacher; receiving feedback from their teacher is extremely important for students (Borasi & Rose, 1989; Jurdak & Zein, 1998; Powell & Ramnauth, 1992). Teachers' responses, comments, affirmation, and challenges based on students' journals are all important aspects of journal writing.

Homework Journals

Based on the literature related to journal writing in mathematics and mathematics education at a postsecondary level, we developed a journal writing assignment, called homework journals. Homework journals, which are based on the structure of Powell and Ramnauth's (1992) description of a "multiple-entry log," are a particular type of writing in mathematics in which students select one interesting or challenging problem from their assigned homework problems. On the left-hand column of a piece of paper, students solve this one problem in detail, clearly communicating their problem-solving process. On the right-hand column of the same piece of paper, students then write a short reflection about this problem and their problem-solving process. This reflection is prompted by a number of suggested topics and questions that students choose from. Teachers read and respond to each student's homework journal with comments, feedback, and questions.

Methods

Context and Participants

The context of this study was a college calculus course, *Elementary Calculus with Trigonometry*. Throughout the semester, students were assigned weekly homework assignments. The homework assignments consisted of 8-10 homework problems. Students were also required to submit a weekly homework journal along with their weekly homework problems. Nine students volunteered to participate in an interview outside of class.

Data Collection and Analysis

The nine students were interviewed using a general interview guide (Patton, 1990). Using a general interview guide allowed the interview to be systematic and comprehensive, but also afforded flexibility with important issues that came up during the interview. One of the main purposes of the interviews was to discuss students' attitudes towards and perceptions of writing in mathematics, specifically related to the homework journals.

A phenomenological design (Rossman & Rallis, 2003) was implemented to explore and describe students' attitudes towards and perceptions of writing in mathematics. The nine student interviews were videotaped and transcribed. The transcriptions were then coded in order to organize, analyze, and interpret the interview data.

Results

For the purposes of this study, we only focus on some of the results concerning what the nine students liked and disliked about the homework journals. The students' likes and dislikes about the homework journals demonstrate whether or not they hold a favorable or unfavorable attitude towards the homework journals and whether or not their perceptions of the homework journals are positive or negative.

What Students Liked About Homework Journals

The students described a number of different aspects of the homework journals that they liked. Students liked 1) the consistency and the format of the homework journals, 2) the feedback they received on the homework journals, and 3) the ability to make choices concerning the

homework journals. Below we elaborate on each of these "likes" and provide descriptions to help understand student's attitudes and perceptions.

Consistency and format. Three students, Mia, Sophie, and Kelly, liked the consistency of the homework journals. In particular, Sophie liked the consistency of the homework journals in that it was something that she did every week and that all of the homework journals were kept together in a single location. Kelly appreciated the consistency between the expectations her instructor communicated and the way her instructor graded the homework journals. Kelly believed that the communicated expectations and the grading practices matched and her instructor followed through with those expectations. Kelly contrasted this with a previous experience with writing in her high school calculus class: "When he [calculus teacher] graded them, he would tell us one thing and then when he graded it, he would be extremely harsh and grade from things he hadn't told us. So it kind of frustrated me more than anything."

Feedback from the instructor. Two students, Lydia and Chris, liked the feedback they received on the homework journals. They both felt that this feedback was an important and meaningful component of the homework journals. Lydia said, "I really like that she always wrote feedback." Lydia went on to describe the feedback she received on her homework journals and how helpful that feedback was, both for gaining a better understanding of the mathematical content and for preparing for tests. Chris also really appreciated the feedback he received on his homework journals. He said, "I like the personal feedback from our instructor, I really like that." The feedback they received from their instructor was very important to both Lydia and Chris and was one aspect of the homework journals that they liked the most.

Making choices. Adele liked that the homework journals gave her the freedom to choose which prompt to answer. She said, "I liked the choice to write about whatever you wanted."

What Students Disliked About Homework Journals

The students described a number of different aspects of the homework journals that they disliked. Students disliked 1) the way that the expectations about the homework journals were communicated to them and how their homework journals were graded, and 2) the open-ended nature of the homework journals. Below we elaborate on each of these "dislikes" and provide descriptions to help understand students' attitudes and perceptions.

Communicated expectations from the instructor. Mia and Chris disliked the way expectations were communicated and the way their instructor graded their homework journals. Mia, for example, felt very strongly about the fact that her instructor had not communicated expectations because, more than halfway through the semester, she still did not understand what was expected of her on the homework journals. She lamented, "I didn't like all the points I missed on them! I feel like that was where I lost most of my homework points because I wasn't able to fulfill expectations in the writing section." Mia does not know what the expectations are and therefore is frustrated because she feels like she cannot fulfill the expectations. Chris also expressed frustrations about his grades on the homework journals. Both Mia and Chris disliked the way the homework journals were graded.

Not enough structure or guidance. Adele and Melissa disliked the open-ended nature of the homework journals; they did not think there was enough structure or guidance to the homework journals. Melissa did not like the freedom she was given to choose which reflection prompt to answer. She explained, "I didn't like that it is kind of open-ended. I'm someone who likes to have very specific directions. So I'll be like, 'What do you want me to write? I'll write what you want me to write if you just tell me what you want me to write!'" Melissa wanted to be given specific instructions about what she was expected to write in her homework journal; she did not

like multiple choices for the reflection prompt. Both Adele and Melissa disliked the freedom of choices they were given with the homework journal.

Discussion and Conclusions

The students' likes and dislikes of the homework journals help describe their attitudes towards and perceptions of homework journals. Most students in this study liked some aspects of the homework journals and disliked other aspects of the homework journals. Therefore, it is difficult to determine whether or not a student entirely held a favorable or unfavorable attitude towards the homework journals or whether or not a student's perception of the homework journal was entirely positive or negative. However, what the students expressed as their likes and dislikes of the homework journals does provide some insight into their attitudes towards and perceptions of homework journals.

Students' likes and dislikes of the homework journals also confirm the strength of the homework journals as a valid and valuable journal writing task in mathematics, based on the three important characteristics of journal writing in mathematics. First of all, some students in the study, like Adele, expressed how much they liked being able to choose which prompt they wanted to respond to and reflect on each week. Although other students in the study, like Melissa, did not like the choice or variety of the prompts, this seemed to be a personal preference for those students. However, both students indicate that they were away of the multiple prompts were presented to students. Secondly, some students in the study, like Kelly, thought there was consistency between what her instructor communicated about the homework journals and the way the homework journals were graded. This provides evidence that expectations were communicated to the students. However, there were other students in the study, like Mia, who did not know what they were expected to write about in their homework journals, confirming the point in the research literature that communicating clear expectations is extremely important. Finally, some students in the study, like Lydia and Chris, valued their instructor's feedback, indicating that there was an opportunity for the instructor to provide meaningful feedback. Homework journals satisfy the three important characteristics of journal writing in mathematics.

While the students' attitudes towards and perceptions of homework journals were varied, it appears that homework journals provide a useful tool for actively engaging students in doing mathematics and reflecting on mathematics and/or mathematics learning by combining problem solving and reflection in a simple two-column format. Similar to the Powell and Ramnauth (1992) study, the students in this study were both actively engaged in doing mathematics and reflecting on that mathematics through the homework journals.

CONTRIBUTION OF THE DIALOGUE BETWEEN TWO THEORIES TO THE STUDY OF TWO VARIABLE FUNCTIONS

María Trigueros — Instituto Tecnológico Autónomo de México — trigue@itam.mex
Rafael Martínez-Planell — Universidad de Puerto Rico en Mayagüez — rafael.martinez13@upr.edu

APOS theory and the Anthropological Theory of Didactics (ATD) are two very different theories in mathematics education. However a dialogue between them has been started. This paper continues the dialogue between these theories starting from a research problem: the learning of functions of two variables. The problem, originally posed within APOS theory, is reformulated and results from the methodological component of the dialogue are applied to its study with the ATD.

Keywords: Advanced Mathematical Thinking; Research Methods

Antecedents and Research Questions

Obtaining information that can be useful in the design of courses or didactic materials is one of the goals of mathematics education. The potential to link effectively theory and practice requires a careful selection of a theoretical framework. Results from a project, where a dialogue between APOS Theory and the Anthropological Theory of Didactics (ATD) was started from the theoretical and the "methodological" components (Trigueros, Bosch, and Gascón, 2011), were used in this study as a way to develop the dialogue, starting from a component or mode of dialogue that was left for future research in that study, and to develop materials to teach functions of two variables.

Function of two variables is an important topic of Calculus and applied mathematics courses. Results from research on this topic (Trigueros and Martínez-Planell, 2010; Martínez-Planell and Trigueros 2012, 2013, Kabael, 2011; Weber, 2012) show the difficulty of this topic as well as specific difficulties observed in students.

Our research questions for this study are: How do the research problems change when studied from the point of view of the result of the dialogue between APOS and ATD?

How can the results from this dialogue be used in the teaching of functions of two variables?

Theoretical Framework

The initial results of a dialogue between APOS Theory and the Anthropological Theory of Didactics (ATD) considered as research praxeologies (Trigueros, Bosch, and Gascón, 2011) are used as a theoretical framework in this study. In the part of the dialogue that starts from the theoretical component of the theories, the notion of a "genetic decomposition" in APOS was specified so that it refers to a "generic student of an institution" and hence could be assimilated to the notion of "subject in position of student" in ATD. This could introduce in APOS the incidence of the institutional interpretation of a concept on its genetic decomposition. A parallelism between the notions of "genetic decomposition" of APOS and "epistemological reference model" of ATD was also found.

Another of the observations from this dialogue was that meeting points between the theories can be found since the genetic decomposition in APOS is formulated in terms of actions that people *in specific institutions* do while doing mathematics and in activities designed for instruction and research where the goal is to help individuals to interiorize actions into processes

or to encapsulate processes into objects, and in the ATD, mathematical activity in institutions *to be done by individuals* is taken into consideration in the analysis of tasks, techniques, technologies and theories which form the basis of the praxeological analysis.

From the part of the dialogue that starts from the "methodological" components of the theories, seen as research praxeologies, it was shown that the notion of institutional relativity of knowledge from ATD can be used to generalize the present role of the genetic decomposition, and the theory of the didactical moments of ATD (Trigueros et al, 2011; Chevallard, 1999) can be taken into account to enrich APOS' ACE cycle.

The institutional relativity of the genetic decomposition can be used to take into consideration the fact that this model can be adjusted to the level of abstraction at which specific concepts are to be taught. The moments of study are a useful tool to analyze the activities designed with the genetic decomposition in order to determine the role that they play in the structure of the process of study.

An Example of Dialogue Between the Theories Starting from a Problem Constructed from APOS

To be able to carry out this dialogue, left as "future research" in the previous study of Trigueros et al (2011), we took a problem that we had already studied from APOS theory and constructed a new problem that could be studied with the tools that resulted from the dialogue starting from the theoretical and "methodological" components. The problem originally formulated in APOS theory as: What mental constructions are necessary for students to learn the concept of two variable functions? Was reformulated in terms of ADT as: In a specific university, what are the characteristics of didactic praxeologies used in the generation of a local mathematical praxeology associated with functions of two variables?

To answer these questions several cycles of research were needed. We report here on the part related to sketching and interpreting graphs of functions of two variables. The first cycle consisted of the analysis of a widely used textbook and the way a representative teacher taught two variable functions at the university (Trigueros and Martínez-Planell, 2011). Conclusions from those analysis indicated that the way the didactical moments of study were transited was insufficient for the students to learn and use the techniques associated to functions of two variables and that in general the organization of the study was not effective.

A set of activities was designed with APOS theory in order to complement the teaching of functions of two variables. The activities were then analyzed independently by two researchers using the didactical moments of study (for a discussion of the theory of the didactical moments see Chevallard, 1999). They compared and negotiated their results until agreement was reached.

Analysis of the Activities Designed with APOS Theory

The design of the activities to foster the constructions included in the genetic decomposition followed a two cycle process where each cycle consisted of: design of activities, classroom implementation, and analysis of results. In each of them the activities were designed using both the didactical moments of study and the genetic decomposition previously designed and validated. In the second cycle the results of the textbook and teaching analysis were also taken into account. The results that follow correspond to the analysis of the final set of activities. All the activities were used in a classroom of the same institutions where the previous parts of the project were conducted and were reviewed in consecutive semesters. The results of the analysis show that different subsets of activities transited the different moments of study. Activities include tasks intended to start students in the construction of subspaces of R^3 which can all be

considered as part of the *moment of the first encounter*; most of the activities related to the result of intersecting fundamental planes with surfaces in R^3 can be considered as part of the *moment of task exploration*. Many of the tasks focus on the interpretation of expressions that contain free variables and that result from the intersection of surfaces with fundamental planes and the coordinate axes, and activities that promote reflection on the processes included in sketching the graph of simple two variable functions in three-dimensional space which can be considered as part of the *moment of task exploration* as well. Through activities designed to coordinate different processes students construct new processes as when the development of a technique to draw cylinders in three dimensions is introduced. These are part of the *moment of work on the technique.*

Tasks that explicitly coordinate the processes involved in the technique for sketching graphs point by point as well as opportunities to coordinate different processes included in the genetic decomposition and that require justification using sections may be considered to be part of the *technological-theoretical moment*, and can help in the encapsulation of processes into objects and in the construction of a coherent schema for R^3. Tasks requiring verification of the correspondence between the sketched graph and the algebraic expression of the corresponding function can be considered to be part of the *evaluation moment* together with tasks that requires the identification of the algebraic representation of two variable functions from a set of surface graphs; In all of them justification of the decision taken using transversal sections is required.

The analysis showed that the variety of activities in the *moment of task exploration* emphasizes the use and importance of transversal sections making explicit the *moment of first encounter with the technique* and the *moment of work on the technique*. Even though the set of activities does not include the explicit discussion of the theory, which is included in the phase of discussion of the ACE cycle of instruction, opportunities for discussion and justification of the methods employed are included and can be considered as part of the *moment of institutionalization*.

This briefly sketched analysis suggest that besides promoting the constructions involved in the genetic decomposition, there is a balance in the introduction of the moments of study and it can be expected that the use of the activity sets contributes to the learning of functions of two variables, although some improvements are still to be made: the number of activities that are part of the *moment of task exploration* needs to be reduced and more activities helping students encapsulate processes into objects may be needed.

Results from the Use of the Activities

A semi-structured interview to 9 students of the group that worked with the activities and 6 students from another group that did not use the activities was conducted. Students in both groups were selected by the respective teachers so that there were an equal number of students who were considered above average, average, and below average, in terms of their results in the course. The interview questions were reviewed by the researchers and the teachers of both groups. The analysis of responses was carried out independently by the two researchers and results were negotiated. The analysis of data showed that few of the students constructed the totality of the structures considered in the genetic decomposition. Students who used the activities did generally better showing a greater tendency to use sections to justify their decisions. Their difficulties were concentrated on the construction of the more difficult processes in the genetic decomposition, such as the intersection of fundamental planes with complex surfaces. The students from the control group showed many difficulties, all of them similar to those found in previous studies and a tendency to rely more on memory.

Taken as a whole, the results show that the use of the activities promotes an organization of the process of study where the transit though the moments of study has the potential to promote students' learning.

The results of this example of dialogue between APOS and ATD theories show that it is possible to use the genetic decomposition in the design of an organization to study functions of two variables that is more effective in terms of learning.

The use of a didactical praxeology in which there is a balance between the moments of study contributes to the construction of the structures hypothesized by the genetic decomposition and to learning the graphical aspects of functions of two variables.

Conclusions

This study contributes to the dialogue between APOS theory and ADT providing an example of a dialogue starting from research problems. The problems, formulated using APOS theory, were reformulated so that they were congruent with the tools developed as a result of the dialogue between the theories. The reformulation made it possible to use the contributions from the dialogue starting from the "methodological" components of the theories as tools of analysis.

Results of this study show that new contributions emerge from the dialogue starting from the problems. The information obtained from the analysis of the textbook, of the teacher, and of the activities developed using APOS theory, together with the refinement of these activities through several research cycles, show that results from the dialogue between the two theories can be used as a powerful tool to determine the elements that should be taken into account in redesigning the original set of activities. The analysis of the interviews from the point of view of APOS shows that most of the difficulties found in previous studies can be surpassed when both cognitive and institutional factors that impact in the learning of functions are taken into account.

The activities resulting from the analysis take into account both the institutional and the cognitive dimensions of this phenomenon and this makes possible a better adaptation to institutional conditions and an equilibrium of the tasks dedicated to the different constructions modeled by the genetic decomposition. The result is reflected in a deeper learning of students.

THE EFFECTS OF VISUAL REPRESENTATIONS AND INTEREST-BASED PERSONALIZATION ON SOLVING PERCENT PROBLEMS

Candace Walkington	Jennifer Cooper	Elizabeth Howell
Southern Methodist Univ.	Univ. of Wisconsin – Madison	Southern Methodist Univ.
cwalkington@smu.edu	jcooper4@wisc.edu	ehowell@smu.edu

Visual representations like illustrations and diagrams, as well as story contexts personalized to interests, may be important supports as students confront challenging mathematical topics. We presented 139 seventh grade students with problem sets on percentages that varied both personalization and visuals. Diagrams helped performance, while illustrations were helpful when used without other supports. Personalized contexts were helpful for the students who had mixed attitudes towards mathematics. This research highlights the importance of considering problem and student characteristics together when making instructional recommendations.

Keywords: Curriculum; Middle School Education; Affect, Emotion, Beliefs, and Attitudes

Theoretical Framework and Literature Review

Mathematics story problems are sometimes considered notoriously difficult to solve (Cummins et al., 1988). However recent work has demonstrated that situated contexts can enhance students' ability to access and apply mathematical ideas. Walkington (in press) found that students solve problems personalized to their out-of-school interests quicker and more accurately. Other research suggests personalization may be most effective for students with lower achievement levels (Anand & Ross, 1987). Complementary research has pointed to the importance of visual representations like diagrams and illustrations for supporting students in solving word problems (McNeil et al., 2009). Research on the *multimedia effect* has found that relevant visual representations that accompany text can increase learning (Mayer, 2005). Cognitive processing capacity, the learner's prior knowledge, and problem difficulty are important determinants of this effect (Kalyuga et al., 1998). Cooper and Alibali (2012) found that diagrams helped all groups of college students on a mathematical task while the effect of illustrations depended on student background characteristics.

Supports like visuals and personalized contexts may provide a means to *ground* mathematical formalisms in students' prior knowledge (Goldstone & Son, 2005) and elicit *interest* – the psychological state of engaging (Hidi & Renninger, 2006). However, research on cognition also suggests reasons why these supports may not be helpful. Cognitive load theory (Sweller et al., 1998) posits that elements that add *extraneous cognitive load* – mental effort stemming from activities not related to learning – may decrease performance by monopolizing available resources. Mayer's *theory of multimedia learning* also accentuates limited processing capacities for separate visual and verbal pathways (Mayer, 2005).

We examine the combined effects of visuals and personalization on solving percentage story problems. Percentages have applications in everyday life, making them a natural site for personalization, and their part-whole relationships afford diagrams. Our research questions are:

1) What are the effects of personalization and visual representations (diagrams, illustrations) on students' accuracy when solving percentage story problems?
2) How do these trends change when taking into account students' reported levels of affect towards mathematics and knowledge of mathematics?

Method

Seventh grade students (*N* = 139, 60 female) at a suburban Southern middle school participated in the study. The schools' students were predominantly Caucasian (46%) and Asian (30%), with 12% eligible for free/reduced lunch and 3% classified as Limited English Proficient.

Students had previously rated their level of interest in a variety of topics (e.g., sports, movies, shopping, food) and subtopics (e.g., basketball, Italian food) on an interests survey. We then selected 8 problems on percentages from a worksheet the teachers at the school were planning to use in their classroom (Table 1) and developed 7 personalized versions for each problem. Personalized versions used the same numbers and information order as the original (Table 2), and had similar Flesh-Kincaid readability levels. All problems expressed simple part-whole relationships using percentages.

Of the 8 randomly-ordered problems each student received, 4 were personalized to each student's highest-rated interests. We also varied whether problems contained diagrams, illustrations, both visuals, or neither visual (Table 3). Additionally, a 12-item questionnaire assessed mathematics attitudes for each student. Factor analysis (PAF) revealed 3 factors on the questionnaire – students' *knowledge* about mathematics (e.g., "I find math confusing"), *value* for mathematics (e.g., "Math is important in everyday life"), and *affect* for mathematics (e.g., "I find many math problems interesting"). Value had no significant effects and is not discussed further.

Students solved the problem set during their math class with a calculator, and their answers were classified as correct or incorrect. Data were analyzed using mixed-effect logistic regression models (Snijders & Bosker, 1999). The dependent measure was accuracy, and predictors included presence of personalization, diagram, and illustration. Random intercepts controlled for elements of the problem's mathematical structure. Students were categorized as high or low on each construct (knowledge, affect) from the attitudes questionnaire by splitting student ratings at the mean.

Table 1: Normal Versions of Percent Problems

Structure	Set 1	Set 2
A	A Southwest Airlines passenger plane can seat 98 passengers. On the Monday flight there were 63 passengers. What percent of seats on the plane have passengers in them?	Kris worked a total of 243 days last year. His work required that he travel out of town on 76 of those days. What percent of the time did Kris's job require him to travel and be out of his office?
B	The Pelican's Club printed color fliers for an upcoming event. They prepared 1468 fliers to distribute. 1282 fliers were passed out. What percent of the fliers are left over?	Mr. Carney is a handyman. He had a total of 130 jobs last month where he either replaced a door handle or installed a sink. Last month, he installed 77 sinks. What percent of his jobs last month involved replacing door handles?
C	Shawn has been shopping for a new office chair. The retail price for the office chair that Shawn likes is $254. On Friday the chair will go on sale for 20% off of the price. How much will Shawn pay for the office chair if he purchases it on Friday with the sale (excluding tax)?	Joey works for an accounting and tax company. The company usually charges their customers $618 per job. However, the company is having a special where all jobs are 30% off currently. What is their discounted charge for a customer who hires them (without tax)?
D	Rene is going to volunteer her time at the local library. She will spend 15% of her volunteer time shelving books. If she has committed to work at the library for 48 hours, how many hours will she spend shelving books?	Last week, Holly worked 68 hours at her office. 70% of that time was spent writing a software instruction manual. How many hours did she spend writing the manual?

Table 2: Examples of Personalized Versions of a Problem

Original	Southwest Airlines passenger plane has a capacity of 98 passengers. On the Monday flight there were 63 passengers. What percent of seats on the plane have passengers in them?
Adventure Games	In your favorite strategy game on the PlayStation, you need to gather 98 gold coins to gain a level. You have currently gathered 63 coins. What percent of the coins have you gathered?
Texting	You have sent 98 text messages on your phone so far today. You notice that 63 of the messages have been to your best friend. What percent of the messages were sent to your best friend?

Table 3: Variations in Visual Representations

	No Illustration	Illustration
No Diagram	Kris worked 243 days last year. His work required that he travel 76 of those days. What percent of the time was Kris out of his office?	Kris worked 243 days last year. His work required that he travel 76 of those days. What percent of the time was Kris out of his office? 
Diagram	Kris worked 243 days last year. His work required that he travel 76 of those days. What percent of the time was Kris out of his office? 	Kris worked 243 days last year. His work required that he travel 76 of those days. What percent of the time was Kris out of his office?  

Results

Did personalization and visual representations influence accuracy?

A diagram by illustration interaction (p = .034) indicated that the combined presence of diagrams and illustrations was equivalent to text alone. Separately, diagrams were superior to text alone (p = .007), and illustrations were marginally better than text alone (p = .06). For the sample as a whole, the effect of personalization was not significant and did not interact with either visual condition (ps > .1).

Did these trends change when taking into account affect and knowledge for mathematics?

Students were classified into 4 groups based on their ratings of knowledge of and affect towards mathematics on their questionnaire: High Affect and Knowledge (HAHK), Low Affect and Knowledge (LALK), High Affect and Low Knowledge (HALK), and Low Affect and High Knowledge (LAHK). Overall accuracy was highest for HAHK students (M = 85%, SE = 5.4%) and lowest for LALK students (M = 74%, SE = 6.6%). For all students, diagram presence significantly improved performance when there was no illustration, but had no effect when an illustration was present. The effects of illustration and personalization were more complex given the three-way interactions of personalization and illustration with reported knowledge, $\chi^2(4) = 10.28$, p = .036, and with reported affect, $\chi^2(2) = 6.55$, p = .038.

For HAHK students, illustrations improved performance when there was no diagram and no personalization; performance was not otherwise affected by personalization. The performance of LALK students was not affected by illustrations or personalization. For HALK and LAHK students, the general trend was for illustrations to be helpful when there was no personalization and no diagram. However, for HALK students, personalization combined with an illustration increased performance compared to personalization alone or an illustration alone. For LAHK

students, personalization increased performance when there was no illustration (p = .008) but the combined effects of personalization and illustration reduced performance (p = .007).

Discussion and Significance

For seventh graders solving percent story problems, diagrams provided an important support. Decorative illustrations and personalization were supportive in more limited circumstances – their effects depended on other supports present and student background. The salience of decorative illustrations and personalization may overwhelm limited cognitive processing capacity when combined with another support. Our interpretation is limited by the relatively small data set given the data complexity and by the specificity to this one type of problem. However, some of the broader patterns from the data suggest important implications. First, when students are struggling, relatively superficial modifications like personalization or illustrations may not help them engage with the mathematics – only diagrams assisted LALK students. Second, decorative illustrations can help performance, suggesting potential differences in the effects of different types of seductive details. Our data cautions against adding other potentially-distracting supports when illustrations are present, however. We conclude that the scaffolding effects of different supports are not necessarily additive and may interact in complex ways.

Students need a variety of supports to access mathematical ideas in the middle grades curriculum. Scaffolds like illustrations and personalized contexts have the potential to ground ideas and elicit interest, but we also need to be aware of some caveats when using these scaffolds. This study broadens current perspectives on mathematical learning by investigating factors that mediate the effectiveness of these supports. Being aware of trade-offs of different supports as well as students' mathematical attitudes and knowledge is important for both curriculum design and in-the-moment instructional decisions.

STUDENTS' LANGUAGE REPERTOIRES FOR INVESTIGATING MATHEMATICS

David Wagner, University of New Brunswick, dwagner@unb.ca
Joseph Dicks, University of New Brunswick, jdicks@unb.ca
Paula Kristmanson, University of New Brunswick, pkristma@unb.ca

We identify the importance of language tools for the development of understanding of mathematics. In particular, language for expressing modality (degrees of certainty) make it possible to express conjecture and thus they support group problem solving. We note ambiguities in meaning in relation to modal verbs (which are used to express modality). Thus we wonder how students with limited language repertoires understand conjecture. We will report on students' language repertoires for conjecture in grades 3, 6, and 9, including first language English speakers in English medium and French Immersion classroom contexts.

Keywords: Classroom Discourse, Problem Solving

Mathematics is mediated through and by language. This is important to educators not only because language is necessary to convey important mathematical ideas, but also because the language used for mathematics shapes the way people conceptualize mathematics. This recursive nature of language compels consideration of students' language repertoires in relation to characteristically mathematical conceptualizations and processes.

Research and professional literature, including curricula and curriculum frameworks, point to the necessity of students learning intended outcomes through the exploration of mathematical problems. This suggests that the investigation of conjectures is one of the most important mathematical processes.

When people explore a mathematical problem together, as with mathematical investigations in classrooms, it is necessary to have a way of suggesting an idea while knowing that it may not be true. Rowland (2000) noted the centrality of such conjecture to mathematics, and coined this "space between what we believe and what we are willing to assert" (p. 142) as the Zone of Conjectural Neutrality (ZCN). Because of the recursive relationship between language and experience, the language resources available affect the possibilities for making conjectures. In our research, we are exploring the ZCN in diverse linguistic contexts. In addition to needing linguistic skill for expressing the uncertainty that is at the heart of conjecture, exploration puts students in a position of having to talk about ideas they do not have experience talking about. They have to invent language or at least invent new ways of using their current language repertoires in order to talk about something they have not experienced before.

In our research project, we are asking:

1. What linguistic resources do mathematics students use to express conjecture?
2. How do mathematics students think about the meaning of such expressions?

We are investigating these questions at a range of levels, gathering classroom and interview data from mathematics students in grades 3, 6, and 9. We are collecting data in French Immersion (FI) contexts, in which students' linguistic repertoires may be relatively narrow, and comparing these contexts to first language contexts, to understand the experience of students in each context and also because we know that the juxtaposition of linguistically diverse contexts is illuminating.

Language and Mathematics Learning

Our investigation is informed by two fields within education research – mathematics education research and second language acquisition research. Though there is diverse research on discourse practices, and language issues in mathematics learning, we are not aware of mathematics education work that focuses on specificities of lexico-grammatical repertoires as they relate to the understanding of mathematical problem solving. However, we are looking forward to a chapter by Edmonds-Wathen, Durand-Guerrier, and Trinick in the upcoming volume from the recent (September, 2011) ICMI (International Congress of Mathematics Instruction) Topic Study Conference on Language Diversity and Mathematics Education, which may open up this area of inquiry. Attention to the distinctiveness of different languages' mathematics registers can help mathematics educators in unilingual and multilingual contexts understand the way language constrains and opens up possible meaning.

The vast majority of the extensive research on French Immersion (FI) learning has focused exclusively on the language and literacy context and not specifically on FI mathematics. Our investigation builds on a small body of Canadian work investigating FI mathematics contexts. It should be noted however that with the exception of Culligan (2010) these studies have focused on achievement in mathematics rather than on particular grammatical or lexical items. With respect to particular linguistic phenomena (e.g., specific language forms; code-switching) that occur in the French immersion mathematics setting, our study expands work done in other contexts of education in an additional language medium (e.g., Setati, Adler, Reed, & Bapoo, 2002).

Our theoretical perspective research draws on the work of Vygotsky (e.g., 1962) and Wertsch (1991), which highlights the connections between thought and language, especially in the process of learning. Language is the main mediational tool in mathematical problem solving, and thus impacts how mathematical knowledge is developed, and how language contributes to that cognitive development process. Exemplifying the shaping force of one's language repertoire, Shaffer (2006) explained how deaf children with hearing parents did not develop "The Theory of Mind" (ability to separate one's self from his or her ideas) because of the absence of modality in their vocabulary. Modality refers to linguistic tools for expressing degrees of certainty; it enables negotiation among different points of view. Shaffer reported that once the children developed vocabulary for modality (in American Sign Language) they quickly developed The Theory of Mind. We note that Rowland's ZCN resembles the space opened up by modality. This suggests to us that students' facility with modality may impact their understanding of mathematical conjecture and problem solving, which depends on conjecture. Nevertheless, if students develop linguistic tools for modality later, we would wonder if their earlier experiences of problem solving without modality might impact the development of their dispositions related to mathematics.

At the ICMI Topic Study conference mentioned above, discussion demonstrated that there is an interest in linguistic variation but not much research, especially not in mathematics education contexts. This discussion also identified the challenge in this kind of research to avoid deficit models, which suggest that one's own way of speaking or thinking is superior (by evaluating whether or not others have acquired the same skills). In the study of linguistic variation for numbers, the one area of mathematics register variation that has been documented significantly, Swetz (2009) pointed out how cultures have been rated on the extent of their number systems. In our research we are not so interested in what an absence of language tools may prevent. Rather we are interested in the potential for linguistic variation to open up opportunities to understand mathematics differently – for example, how does thinking of numbers as verbs (see Lunney

Borden, 2010) change one's conception of counting and arithmetic operations? We know that students, including second language (L2) students, use grammatical structures to express modality at some point, but we wonder what other resources they might use if the usual modality tools are not in their linguistic repertoire. And how do they think about what the modulation means? It is important to investigate these questions along a range of linguistic proficiencies.

Modality and Conjecture in Unilingual Contexts

Modality has been studied in English-medium mathematics teaching and learning contexts, first by Morgan (1998). Much of this work, including our own, focuses on the way high modality (language that expresses a high degree of certainty) and root modality (language which suggests that there are no alternatives possible) can restrict discussion and obscure human agency. Modal verbs are often used to express degrees of certainty. For example, the modal verb *must* suggests more confidence (e.g., "it must be prime") than *could* (e.g., "it could be prime"). We say an expression has high modality if it has more certainty. When there is absolute confidence (e.g., "it is prime"), there is no expression of degree of certainty. Rowland (2000) called this root modality. "It must be prime" suggests a recognition that others may disagree, unlike the expression "it is prime." This recognition of multiple possible points of view allows one to put forward an idea for testing (i.e. conjecture) – the idea seems true but can be tested from another point of view.

We began to notice modality in an earlier research project that involved FI mathematics classrooms (Wagner, Herbel-Eisenmann & Kristmanson, 2011). We noticed ambiguities in English modality that could seriously impact students' understanding of mathematics. Martin and Rose (2005) identified five types of modality, which describe degrees of certainty relating to usuality, probability, obligation, inclination and ability. For example, "we sometimes add" refers to usuality, and "I might add" refers to inclination. These examples also show that there are ways of introducing modality without using modal verbs. This is why our research questions are open to a range of linguistic resources for conjecture, not just modality.

But the modal verbs carry muddy meaning because of intertextuality. For example, the meaning of the verb *can* differs depending on context: "You *can* be excused from the table" indicates a degree of obligation, "You *can* finish the race" indicates ability, "I *can* help you" indicates inclination and "It *can* be red (because there are three red marbles in a bag of marbles)" indicates probability. When students hear the word *can*, what does it mean to them? Do they distinguish between obligation and probability?

Even within obligation there are distinctions to be noted, for which we raise the same questions about students' perceptions of the meaning. For the modal verb phrase *have to*, which indicates obligation, we would expect that mathematics understanding requires a distinction between obligation due to personal role (or status) and obligation due to logic. For example, "We *have to* cancel the *x*'s to simplify the fraction" suggests an obligation attributable to logic, and "We *have to* cancel our dinner reservation" indexes obligation attributable to interpersonal positioning. When students hear *have to*, how do they understand this obligation? It is important to note that students hear *have to* very often in mathematics class, as demonstrated by Herbel-Eisenmann, Wagner and Cortes (2010) in their analysis of a large body of mathematics classroom interactions across a range of classrooms. Expressions intended to describe logical obligation may be taken by students as obligation due to interpersonal positioning. The muddiness of meaning in modal verbs exists in French too.

Methodology and Results

We are collecting a range of data from multiple points of view on students' linguistic

resources for expressing and understanding conjecture in mathematics contexts. Starting from grade 3 (when early French Immersion begins in our region) we are beginning to follow groups of students as they develop their linguistic and mathematical repertoires. We are following these groups starting from grade 3, from grade 6 (the beginning of middle school), and grade 9 (the beginning of high school). We will follow each group for three years to get a sense of students' development of their language repertoires.

In each participant classroom, we record small group problem solving and then interview students the day after the problem solving. We record audio and video because our focus is on language resources, which can include gesture and physical positioning of interlocutors. In our analysis of the recordings and transcripts, we will look for development of students' linguistic resources from year to year, but we are already interested in the snap shots of the linguistic resources in any given session. Our experiences studying language practice have made clear to us the futility of generalizing the language practice of any category of children. Instead, we are interested in illuminating the diversity of practice.

In our presentation, we will represent the range of language resources used by participant grade 3, 6, and 9 students in their mathematical problem solving and in their talk about that problem solving (in our follow-up interviews). We have recently begun our data collection. By the time of the conference, we will have collected our grade 3, 6, and 9 data and we will have had five months to analyze it.

THOMSON'S LAMP AND THE GREEN ALIEN: EXPLORING INFINITY VIA SUPERTASKS

Chanakya J. Wijeratne

Rina Zazkis
Simon Fraser University
zazkis@sfu.ca

In previous studies paradoxes of infinity have been used in the investigation of conceptions of infinity of pre-service high school teachers and university students. In this study the Thomson's Lamp paradox and a variation of it, the Green Alien, were used to investigate the naïve and emerging conceptions of the infinity in a group of liberal arts university students and the effect of context on such conceptions. This study contributes to research on the use of paradoxes in mathematics education and to research on understanding infinity, with a focus on infinitely small quantities.

Keywords : Cognition, Advanced Mathematical Thinking

Introduction and Theoretical Perspectives

Paradoxes have been used as a lens in mathematics education research. Movshovitz-Hadar and Hadass (1990 & 1991) investigated the role mathematical paradoxes can play in the pre-service education of high school mathematics teachers. They concluded that "a paradox puts the learner in an intellectually unbearable situation. The impulse to resolve the paradox is a powerful motivator for change of knowledge frameworks." (Movshovitz-Hadar and Hadass, 1991, p. 88). Sriraman (2008) used the Russell's paradox in a 3-year study with 120 pre-service elementary teachers and studied their emotions, voices and struggles as they tried to unravel the paradox. Mamolo and Zazkis (2008) used the Hilbert's Grand Hotel paradox and the Ping-Pong Ball Conundrum to explore the naive and emerging conceptions of infinity of two groups of university students with different mathematical backgrounds.

Paradoxes such as Achilles and the tortoise, and the Ping-Pong Ball Conundrum are super-tasks. "A super-task may be defined as an infinite sequence of actions or operations carried out in a finite interval of time" (Laraudogoitia, 2011). In our study we focus on a particular super-task, known as the Thompson's Lamp, devised by Thompson (1954) to show that super-tasks are impossible.

> Think of a reading lamp with an on/off switch button. Suppose that the button can be pressed in an instant of time. Suppose at the start the lamp is off. After 1 minute the button is pressed and the lamp is on. After another 1/2 minute the button is pressed and the lamp is off. After another 1/4 minute the button is pressed and the lamp is on, and so on. That is, the on/off position of the lamp is flipped when exactly one-half of the previous time interval elapses. At the end of the two minutes, is the lamp on or off?

Thompson (1954) argued that the lamp cannot be on as it is never turned on without turning it off some time later. And similarly the lamp cannot be off. Therefore a contradiction arises and Thomson's lamp, or any super-task, is logically impossible. Benacerraf (1962) argued that the above reasoning is valid only for any instant between 0 and 2 minutes, but not at exactly 2 minutes.

In this article we study the struggles with the concept of infinity of a group of university students using the Thomson's Lamp paradox and its isomorphic version, the Green Alien, explained below. Several theoretical frameworks informed our investigation. We use APOS

theory (Dubinsky, Weller, McDonald & Brown, 2005a), reducing abstraction by Hazzan (1999), and platonic and contextual distinction by Chernoff (2011).

APOS theory (Dubinsky et. al., 2005a) suggests that an individual deals with a mathematical situation by using the mental mechanisms *interiorization* and *encapsulation* to build the cognitive structures *actions*, *processes*, *objects* and *schemas* that are applied to the situation. Researchers have acknowledged the difficulty in transitioning from process to objects conceptions. Focusing on this difficulty, Weller et al. (in press) introduced the construct of 'Totality', which is a "part of the mechanism of encapsulation, not a separate stage", but a step one goes through before the process is encapsulated to an object. Totality indicates, as its name suggests, the ability to relate to the entire process, to all the steps at once, rather than in a sequence. Another theoretical framework we use is reducing abstraction by Hazzan (1999). According to Hazzan (1999) there are three ways in which abstraction level can be interpreted: (1) Abstraction level as the quality of the relationships between the object of thought and the thinking person, (2) Abstraction level as reflection of the process–object duality, and (3) Abstraction level as the degree of complexity of the mathematical concept. We also rely on the theoretical constructs introduced by Chernoff (2011) in distinguishing between platonic and contextualized situations. Chernoff distinguished between platonic and contextualized sequences in the relative likelihood tasks in probability. A platonic sequence is characterized by its idealism. But, a contextualized sequence is characterized by its pragmatism.

While mathematical paradoxes are presented in a context, the resolution of the paradoxes requires a thought experiment and de-contextualization from the physical reality, that is, accepting the idea that a super-task can be completed in the given time interval.

The Study

Participants in our study were 38 undergraduate liberal arts students. The students were introduced to the Thomson's Lamp paradox and they were invited to express their thoughts on whether the lamp was on or off after exactly two minutes. Then the Thomson's argument that shows the logical impossibility of super-tasks was discussed. This was presented as yet another point of view, rather than an authoritative conclusion. Then an extended discussion, in which the participants had an opportunity to argue and convince each other followed. The whole session on the Thomson's Lamp was recorded. Two weeks after the discussion on the Thomson's Lamp, the students were presented with the following Green Alien problem, to which they were asked to respond in writing and justify their answer.

> A Green Alien arrived in the earth at midnight, November 5, and she has exactly 1 day to spend on our planet. That is, she MUST leave at midnight, November 6; otherwise she will change into a pumpkin. However, she learns that FBI is after her, so at noon, November 5, she instantaneously changes her color to pink (to blend in with the local girls). When the search intensifies, she changes the color back to its original Green at 6 pm, and keeps changing it at half-intervals of the remaining time, as follows: Midnight (12 AM November 5) – Green, Noon (12 PM November 5) – Pink, 6 PM – Green, 9 PM – Pink, 10h 30min PM – Green, 11h 15min PM – Pink, 11h 37min 30 sec PM – Green, 11h 48min 45 sec PM – Pink … What color is she at midnight, as she leaves the earth?

Our data consist of students' arguments in considering the Thomson's Lamp during classroom discussions, and their written responses to the Green Alien problem. Note that the Green Alien problem is isomorphic to the Thomson's Lamp paradox, but the context is changed from the familiar light switching to science fiction. In what follows we analyze students'

responses to the two versions of the super-task and the effect of context to their emerging conceptions of infinity.

Results and Analysis

In the process of halving the remaining time in Thomson's Lamp, one has to deal with an infinite number of time intervals in a finite time interval. This can create a cognitive conflict and tension. This state of cognitive conflict, according to Movshovitz-Hadar and Hadass (1991), creates uneasiness. Piaget calls it as a state of disequilibrium between assimilation and adaptation-accommodation. This state, and the tension it creates, stimulates an attempt to get out of it and achieve a new equilibrium with a more advanced mental structure (p. 80). We present here some ideas that emerged in the classroom discussion that show the cognitive conflict and various, at times implicit, ways of achieving equilibrium.

An idea expressed and accepted by several students during the extended discussion was that "it will never reach two minutes". Equilibrium is achieved with this claim, as it frees students from deciding on the state of the lamp at the end of 2 minutes. However, having recognized the absurdity of this claim, some students struggled to reconcile the idea of infinitely many time intervals within two minutes. For example, on one hand Jason says it (time) does not reach 2 minutes but on the other hand he considers the status of the lamp at 2 minutes using ideas resembling Thomson's argument. Inconsistency in Jason's response shows the cognitive conflict he is experiencing. The inconsistency in students' claims can be attributed to their inability to consider the process in its totality, which is essential according to Weller et al. (in press) in encapsulating the infinite process.

We note these students' reference to numbers, rather than time intervals. For example Jason thinks of numbers that are "too small": "there is no way of knowing whether it will be on or off because the numbers get too small, and will not reach 2 minutes". We observe here students' attempt to reduce the level of abstraction by considering numbers, rather than considering very small time intervals, which are unfamiliar and hard to conceive.

While only several students clearly expressed their views during classroom discussion on Thomson's Lamp, we wondered whether these views were shared among other students. As such, we designed the Green Alien problem and collected written responses from the 38 students in class, which we present in this section. We identified several interwoven themes in students' responses (the number in parenthesis is the number of responses): contextualization (6), halving time goes on forever (3), never reach midnight (7), impossible to determine (15), acknowledgement of paradox (9), and connection to Thomson's Lamp (3). In several works more than one theme was featured. Due to limited space, we exemplify only a few of these.

Out of 38 responses, six showed a clear contextualization. For example, one student wrote "the poor alien will be changing back and forth so many times as the midnight comes nearer that she will feel sick and wish to go home to bed anyway". These attempts in contextualization of an imaginary situation are indications of reducing abstraction from unfamiliar (instantaneous change of color) to the familiar (being tired). Some considered the situation as paradoxical. Those who expressed the opinion that halving time continues forever and never reaches midnight often concluded that it is impossible to determine the color.

Gilbert was one of three students who suggested that halving time goes on forever. But he introduced an additional idea: "since the time will continue to halve itself forever she will be both green and pink at her time of departure at midnight". The reference to "both green and pink" can be seen as a halfway color between green and pink. This view is in accord with taking ½ as the sum of Grandi's series ($S = 1 - 1 + 1 - 1 \ldots$) if green and pink are assigned 0 and 1

respectively, and turning pink is considered as adding 1 and turning green is considered as subtracting 1. Though it is highly unlikely that Gilbert thought this way, his answer shows some signs towards considering the process of halving the remaining time in its totality.

Conclusion

Paradoxes of infinity puzzled people for centuries, so it is not surprising that our students exhibited some confusion and presented arguments that lacked internal consistency. It is evident that only a few students claimed that the color of the alien at midnight was impossible to determine, presumably accepting the 'normative' resolution. However, the reasoning behind this suggestion often relied on arguments suggesting that midnight cannot not be reached.

The particular paradox discussed in this article relies on the idea of halving the time interval infinitely many times. Can something be halved indefinitely? Stavy and Tirosh (1999) explored this issue with learners in their study of intuitive rules. In fact, the answer depends on the interpretation of the question. If a line segment is divided in half, then the process can continue indefinitely, as a segment is an abstract mathematical object. If a piece of copper wire is divided, then the process must end when reaching an indivisible unit. However, what about time intervals? The added difficulty of the super-tasks that students discussed was that they were presented in a context, but were to be considered platonically, that is, disregarding the context of time. We wonder whether the fictitious context of an alien provides a more accessible avenue to consider super-tasks than a 'realistic' context of switching a lamp unrealistically fast.

The cognitive conflict and the resulting tension a learner experiences in thinking of the Thomson's Lamp or the Green Alien can be a powerful motivator to unravel the notion of 'infinitely small' and understand its formal aspects. Coupled with the Grandi's series it can provide a rich task for liberal arts students to explore, to struggle with, and to experience fascination with ideas and the formal aspects of infinity.

MEANINGFUL LISTENING THROUGH COHERENT CONCEPTUAL METAPHORS

Sean Yee
California State University, Fullerton
syee@fullerton.edu

Metaphors span language in many forms. Mathematics educators regularly use metaphors to relate one mathematical concept in terms of another. Embedded within these concepts are a set of shared experiences that educators use to communicate new ideas to students. However, students also use metaphors to convey their experiences, perceptions, and understanding. This paper reports on a mixed-methods study that discovered a coherent set of metaphors that high school students and teachers associated with mathematical problem solving. The existence of a coherent system of metaphors for problem solving offers a starting point for discussing problem solving experientially. It also opens new methods in student-teacher discourse. Specifically, this methodology helps teachers learn how to listen hermeneutically for student experiences and is being developed for teacher professional development.

Keywords: Classroom Discourse, Problem Solving, Teacher Education, High School Education

Introduction

This study applied Conceptual Metaphor Theory (CMT) as a means to analyze students' problem solving experiences. The results are twofold. First this paper presents the results mixed-methods study that identifies student and teachers perceptions of mathematical problem solving using metaphors. Secondly, this paper takes this study's novel methodology and suggests it is useful for teacher development in discourse (Sfard, 2009). Specifically, the researcher explores the opportunity for CMT analysis to move teachers from a constructivist paradigm of interpretive listening to a hermeneutic model of listening for conceptual understanding (Davis, 1997).

Literature

Often within education, the purpose of metaphors are to share one person's experiences through common experiences (or experiences believed to be common) (Ortony, 1993). This study identifies the shared experiences teachers and students associate with mathematical problem solving, because problem solving lacks a cohesive definition agreed upon within the mathematics education community (R. Lesh & Zawojewski, 2007; Polya, 1945; Schoenfeld, 1985; Shumway, 1982; Silver, 1985). Nonetheless, there are coherent shared experiences drawn upon by mathematics educators to work with problem solving (Chapman, 1997; R. A. Lesh & Doerr, 2003; Shumway, 1982; Silver, 1987). Thus this study identifies if metaphors associated with problem solving are a means to describe and identify a coherent set of shared experiences for discursive practices.

Fundamentally, this study's epistemological framework aligns with Sfard's (2009) work on discourse for cognition via participation and acquisition. Despite all the mediums through which one must interpret student and teacher perceptions of mathematical problem solving, the student and teacher try to communicate their personal experiences through a set of presumed shared experiences (Yee, 2012). These shared experiences are fundamental because the assumption of what students and teachers perceive as shared experiences define their interpretation of problem solving (Sfard, 2009). This study used conceptual metaphors (Lakoff& Johnson, 1980) to identify the shared experiences embodied within mathematical problem solving.

A conceptual metaphor is a mapping, an identification of the experience to be expressed (the target domain) and the experience to be shared (the source domain) (Lakoff & Johnson, 1980). For example, a student said during my interviews, "to solve it for me, it meant that I had to find it

somehow." The student used the conceptual metaphor: PROBLEM SOLVING IS SEARCHING. Thus the student was sharing how their understanding of problem solving (target domain) is perceived as searching (source domain) (Kövecses & Benczes, 2010). The student communicates this because they believe the researcher has shared the experience of searching and so relates this perception to the researcher. Due to the specifics of each domain, it is important to note that this is a unilateral relation: TARGET DOMAIN →SOURCE DOMAIN.

This study generates a unique methodology that is replicable, but more importantly, a practical means to aid teachers in listening to their students understanding.

Method

Participants for this study included 22 independent honors geometry student interviews and 6 independent teacher interviews from both honors geometry teachers in a suburban high school. The students and teachers both met with the researcher individually for 10-15 minute semi-structured interviews about specific problems from one of three recent common assessments designed and determined by the teachers. The teacher interviews focused on how teachers expect students to solve problems, while the student interviews focused on how students had solved the problems.

Results

The CMT analysis discovered some surprising relationships between teacher and student thinking. Table 1 is a list of source domains used by students, and source domains used by teachers related to problem solving.

Table 1:Teacher and Student Source Domains for Mathematical Problem Solving

Only Student Source Domains	Source Domains of Student and Teacher	Only Teacher Source Domains
ABILITIES	ACQUISITION	CHANGE OF STATES
APPROXIMATING	BUILDING	CONFLICT
CALCULATING	DISCOVERY	DOING BUSINESS
COMPARING CONDITIONAL	IMAGINING	FAMILIARITY
CONTEST	JOURNEY	GENERALIZING
CONVINCING	PARTITIONING	HABITS
EXPERIMENTING PROVING	PROCESS	RACE
THINKING	REVIEWING	RULES
VOCALIZATION	SEARCHING	SETS OF SKILLS
	VISUALIZATION	TOOLBOX
	WAR	UP

PROBLEM SOLVING IS SEARCHING was one dominant form of metaphorical discourse. The following statements from teachers and students do indicate that searching is a consistent source domain. Student5 explained, "There is probably like a missing side or missing angle or something." Student7 clearly stated, "to solve it for me it meant that I had to find it somehow." Teacher2 stated that his students would "have to go searching for them." Thus, the conceptual metaphor of searching was frequented through the perception of "finding" the "missing" solution. This structural metaphor is grounded in one's experiences searching for objects. Additionally, other source domains were regularly entailed (Kövecses & Benczes, 2010) with searching because one's experience in searching develops with other concrete experiences, such as journey.

PROBLEM SOLVING IS A JOURNEY was by far the most abundant metaphor for problem solving. Inherently, everyone travels and was identified frequently as a grounded metaphor. The most common mapping to journey occurred when student's referred to "the way" to solve a problem. In this manner, the experiential "way" is short for passage way. Student3 stated, "I couldn't really

think of a way to solve it and if I did find a different way to solve it wouldn't have been as easy". Student15 stated "I'm not sure if you could find a different way but I'm sure there are other ways". Teacher1 stated, "I don't have any issues with them doing it that way as long as they still have all needed stuff that's there." As a primary conceptual metaphor, "way" is being used as a path or trail, but as a complex metaphor, the aspects of this path or trail emphasize the journey the student is on to solve the problem.

To see these connections more clearly, notice the following other aspects of journey as described by the students and teachers. Teacher2 mentions that as the students "use the short cut conjectures that we've talked about." The source domain of journey occurred more subtly in some student's interviews. Consider Student12's statement, "I don't know, that wouldn't have gotten me too far. What is enlightening about the use of journey is that teachers encourage students to believe that the journey is equally credible in solving math problems.

The quantitative results demonstrated a strong similarity between the most popular and most frequented source domains. Table 2 demonstrates these results:

Table 2: Comparison of Teacher and Student Source Domains for Problem Solving

Students' Most Frequented Source Domains	Students' Most Popular Source Domains	Teachers' Most Frequented Source Domains	Teachers' Most Popular Source Domains
26% JOURNEY	95% JOURNEY	29% JOURNEY	100% JOURNEY
18% SEARCHING	86% VISUALIZING	17% DISCOVERY	100% DISCOVERY
13% VISUALIZING	82% SEARCHING	11% BUILDING	83% SEARCHING
12% DISCOVERY	73% PROCESS	10% VISUALIZING	83% BUILDING
9% PROCESS	68% BUILDING	7% PARTITIONING	67% VISUALIZING
8% BUILDING	68% DISCOVERY	7% SEARCHING	50% PROCESS
8% PARTITIONING	55% PARTITIONING	6% PROCESS	33% PARTITIONING
			33% RACE
			33% SETS OF SKILLS

Despite more popular source domains from the teachers, the top seven source domains remained the same in popularity and frequency for both teacher and student. These results demonstrate a coherent system of conceptual metaphors within mathematical problem solving in these high school honors geometry classrooms. PROBLEM SOLVING IS A JOURNEY, SEARCHING, VISUALIZING, A PROCESS, DISCOVERY, BUILDING, and PARTITIONING.

Other analyses were done with respect to the data, such as comparing the students' score with the frequency and popularity of the metaphors. Surprisingly, with every single student metaphor, no correlation was significant with student performance. Not a single metaphor suggested a positive correlation with a student's score on an assessment. This is remarkable and encouraging as many mathematics educators strive to demonstrate multiple representations.

Discussion

The result of this study used mixed methods with a phenomenological qualitative analysis (CMT) to identify coherent set of source domains (i.e. shared experiences) that students and teachers associate with mathematical problem solving. It is vital that this research is not misinterpreted. This study has only shown existence of a coherent metaphorical system, not uniqueness. This data is not attempting to prescribe these source domains as the only source domains for problem solving. Instead, this study validates the prescription for the methodology and the use of CMT analysis as a means to identify localized coherent conceptual metaphorical systems.

As embedded within the PME-NA theme, this study broadened through linguistic interdisciplinarity. This can be incredibly beneficial in improving how teachers listen, thus improving mathematical thinking in the classroom. As this study contained only six teacher interviews, a current study is underway to interview 30 pre-service, practicing, and master teachers' perceptions of problem solving using this methodology.

The significance to teacher listening can be perceived from the pervasive need for all teachers to see metaphors as necessary for communication at all levels of education (Petrie & Oshlag, 1993). Davis (1997) discovered through a series of vignettes that mathematics teachers listen at three levels: evaluative listening (assessment-based paradigm), interpretive listening (constructivist paradigm), and hermeneutic listening (conceptual participation paradigm). The third form of listening Davis suggests is what teachers should strive to develop, an immersed perspective of genuinely participating and sharing in the cognitive experiential development of the meaning behind the mathematical topic. Problem solving was only one means to discovering this methodology, but not its only use. This research proposes is that CMT analysis allows for this participatory conceptualization by analyzing, interpreting, and listening for the shared experiences of the students through conceptual metaphors.

AFRICAN AMERICAN MALES AND MATHEMATICS AS THE "INTELLECTUAL PROPERTY OF WHITENESS"

Audrea Bankston
Georgia State University, Graduate Student
abankston4@student.gsu.edu

Keywords: Equity and Diversity, Policy Matters

If one were to visit an Advance Placement Calculus class, one would typically find only two African American males in the course. "In the United States, remedial mathematics classrooms contain large numbers of African American students; however, advanced mathematics classes mainly serve White students" , (as cited in Snipes & Waters, 2005, p. 107). African American students especially males do not have the opportunity to take advance math classes in high school. Early on in their schooling, many African American males experience failures in mathematics. According to Ladson-Billings, "as a group, African Americans have been told systematically and consistently that they are inferior, that they are incapable of high academic achievement" (as cited by Jackson & Wilson, 2012, p. 357). In her analysis of the cause, she thinks that it is systemic problems stemming from the remnants of slavery; where African American students fulfill the inferior prophesy. Ladson-Billings introduced the concept of mathematics as intellectual property in her research (Snipes & Waters, 2005). Ladson- Billings stated that mathematics courses are still viewed as "intellectual property" that is afforded to the dominant culture (as cited in Snipes & Waters, 2005, p. 110). This sense of owning property symbolizes power (Snipes & Waters, 2005).

Critical Race Theory, where race is used as the signifier that oppresses and symbolic interactionism, where the world is interpreted based on experience, will guide an ethnographic study of the African American male perspective of mathematics as the property of whiteness (Ladson-Billings, 1998; Roulston, 2012). In the proposed study, a group of African American males will serve as a culture that does not have access to mathematics, where their perspective will be examined to deduce their interpretation of the current practice of mathematics as the gateway course.

Current research studies by scholars such as Ladson Billings and Moses, examine the issue of the disproportionate representation from an adult point of view. However, there is not enough research of what the students think about the lack of access in mathematics and how mathematics courses determine their destiny in life. In conducting this study, academia and the public would have information from the student's perspective and could change the practice of excluding the African American students' voice from the table of policymaking.

ONLINE OR PROCTORED: AN INVESTIGATION OF TWO SETTINGS FOR A MATHEMATICS PLACEMENT TEST

Peter Banwarth
Oregon State University
banwartp@math.oregonstate.edu

Keywords: Post-Secondary Education, Data Analysis and Statistics, Assessment and Evaluation

Motivation for the Study and Theoretical Framework

A major driver of student success in mathematics is self-efficacy (Zajacova, Lynch, & Espenshade, 2005), which can be negatively influenced when students enroll in mathematics courses that do not match their level of preparation (Bassarear, 1986). Some post-secondary institutions have replaced a proctored mathematics placement test (MPT) with an un-proctored, online one to inform students of their preparation. This quantitative study adopts the stance that accurate information provided by the MPT positively affects student self-efficacy, so it is important to determine the accuracy of the MPT in an online setting versus a proctored setting.

Data Collection and Analysis

Data Collection

Student data on MPT scores and fall term grades were obtained from a large public university. The sample was restricted to students who entered as freshman in either fall term 2010 (online MPT) or fall term 2011 (proctored MPT) and enrolled in one of four fall term mathematics courses. Variables included MPT scores and participation rates and course grades.

Analysis

Summary statistics. In 2010, the MPT participation rate was 98.26%, while in 2011, the MPT participation rate was 96.25%. The participation rates were statistically equivalent across years. In each of the four courses, the mean MPT score was approximately 2 points higher in 2010 than in 2011, with equality of means rejected.

Hypothesis tests. Three linear regression models were employed to test the predictive power of MPT score on fall term grade. The results of the models indicate that (1) the predictive power of the MPT score is consistent across the four courses studied, (2) an increase in one standard deviation above the mean score within a course predicts a 0.33 grade point increase, and (3) the predictive power of the online MPT is statistically equivalent to that of the proctored MPT.

Discussion

The results of the analysis indicate that the online MPT predicts student success with the same level of accuracy as the proctored MPT. Therefore, the information provided to students by an online MPT is valuable to students. By using their MPT scores to help choose courses, students' preparation will be better matched to the course content and they will also likely have higher levels of self-efficacy and therefore greater success in their mathematics courses.

RESOURCE USE OF PRESERVICE ELEMENTARY TEACHERS IN AN INQUIRY-BASED LEARNING MATHEMATICS CONTENT COURSE

Anne Cawley

Students in mathematics content courses use resources both within and outside of the classroom. We examine how preservice elementary teachers in an inquiry-based mathematics content class use available resources for their learning. We also are interested in what impacts the ways students use these resources. We interviewed and observed three students from an inquiry-based mathematics content course for preservice elementary teachers to investigate the resources they used (e.g., family members, peers, small groups, poster presentations, instructor, readings, colored pens). By analyzing how and why students used these resources, we identified three main recurring themes, two about specific resources (individuals and small groups) and one about the rationale for using a variety of resources (motivation). In this paper we discuss each of these themes in detail.

Keywords: Teacher Education-Preservice, Post-Secondary Education

We examine undergraduate students' use of resources in order to inform those who design instruction for these students. We define resources as anything the students use to help them learn (e.g., people, Internet, textbooks). Specifically, we focus on preservice elementary teachers' use of resources in an Inquiry-Based Learning (IBL) mathematics content course. The unique nature of IBL courses provides an interesting site to study students' resources, as the course requires students to do explorations on their own by playing a more active role. While the topics covered in elementary mathematics content courses are considered to be quite basic, the focus of these courses—to develop deep conceptual understanding of ideas that students generally know in a procedural sense—causes many students to find these courses surprisingly challenging, even when they have been successful in high school and higher-level mathematics courses. It is suggested that preservice teachers need to develop the capacity to explore resources and situations in classrooms in order to develop their expertise (Edwards & Protheroe, 2003). We conjecture that the resources available to students in this environment are different from the resources that are normally available in a lecture-based class and that specific features of IBL courses may influence students' use (or lack of use) of those resources.

We proposed the following two research questions: How do preservice elementary teachers in an inquiry-based learning mathematics content class use available resources for their learning? What influences the ways students use these resources?

Analysis of the data highlighted prominent themes: resources (what), use of resources (how), and reasons for using resources (why). We came to understand the learning process as a function of how and what resources students use, which is contingent on why students make those decisions. Considering the results, educators who design instruction that incorporates IBL, especially for preservice elementary teachers, should consider the use of specific resources available to students as well as how and why they are used.

Keywords: Early Childhood Education, Affect, Emotions, Beliefs and Attitudes

The family environment has been found to be positively correlated with a child's academic success (Haile & Nguyen, 2008), providing stimulation for curiosity and encouragement to explore their interests with positive beliefs, attitudes, behaviors, and values. Parental involvement in educational activities as well as parent perceptions toward pursuits of learning a particular subject (Bleeker & Jacobs, 2004) has been shown to be influential to a child's academic achievement. Mentors and peers can also be a powerful influence in shaping a child's development. Advice from a mentor at the right time can have the potential to change a person's life (Muratori et al., 2006), and peers can provide the right amount of support and competition to influence academic achievement as well as influencing college and career decisions (Ryan, 2001). Competitions, out-of-school camps, and private and group tutoring such as the "Ha-Gwon" in Korea have been shown to provide additional influence in terms of academic achievement and motivation for students (Kim, 2008).

This study examined sources of out-of-school influence through interviews with five Korean International Mathematical Olympiad (IMO) winners and looked at their influence on academic achievement and development. We studied Korean students for this country's history of high performance, scoring in the top five during four of the past five years.

We conducted a series of three in-depth interviews with five IMO winners and three parents about these IMO winners' life experiences that contributed toward their academic achievement and development of talent and interest for mathematics. Interviews were conducted in Boston, MA and various cities in Korea. We started with a list of out-of-school factors, such as parents, peers, mentors, and competitions from previous research (Karp, 2003; Muratori et al., 2006) and employed grounded theory techniques to attempt to discover factors of influence common to Korean culture that have not yet been disseminated in other studies. Constant comparative methods of analysis were used to discover differences and similarities in the data as compared to the categories of influence previously mentioned.

Analysis revealed five major sources of out-of-school influence. Family members, peers, mentors, participation in mathematics camp, and the effects of mathematics competitions are influential sources that have been discussed in previous research. Mathematics workbooks and Ha-Gwon surfaced as sources of influence that were seldom previously mentioned.

Purpose

Prior research has shown a relationship between identity and student persistence and engagement toward mathematics or mathematics-related fields (Boaler & Greeno, 2000; Cass, Hazari, Cribbs, Sadler, & Sonnert, 2011). In this study, mathematics identity is discussed as a way of explaining student persistence in mathematics and conceptualized as how students see themselves in relation to mathematics based upon their perceptions and navigation of everyday experiences with mathematics (Enyedy, Goldberg, & Welsh, 2006). The purpose of this study is to test two aspects of a mathematics identity framework guided by the following research questions 1) What is the relationship between mathematics identity and students' career choice as a mathematician and a math/science teacher; and 2) Does the framework adopted in this study provide a global view of students' mathematics identity?

Methods

Logistic regression was used to address the first research question using data from the FICSMath project, which was administered in the fall of 2009 yielding 10,437 surveys. A proxy for mathematics identity was used based on results from a previous analysis (Cribbs, Hazari, Sonnert, & Sadler, 2012). A Wilcoxon paired t-test was used to address the second question using data from a follow up study administered in the summer of 2012 yielding 131 surveys.

Results

Only control variables with a significance level of $p < 0.01$ were included in the final model. The first regression model predicting career choice as a mathematician indicates that Father's Education and ACT_SAT Score were significant. In addition, the results indicate that mathematics identity significantly predicts students' career choice as a mathematician ($p < 0.001$). The second regression model predicting career choice as a math/science teacher indicates that Gender, Race: Black, Race: Asian, Father's Education and ACT_SAT Score were significant. In addition, the results indicate that mathematics identity significantly predicts students' career choice as a mathematician ($p < 0.001$). Results for research question two found that mathematics identity remains relatively stable over time with a non-significant p-value.

EXPLORING CONNECTIONS BETWEEN STORY PROBLEM TOPICS AND PROBLEM SOLVING: IS WORK HARD AND SOCIALIZING EASY?

Virginia Clinton	Candace Walkington	Elizabeth Howell
Univ. of Wisconsin-Madison	Southern Methodist University	Southern Methodist University
vclinton@wisc.edu	cwalkington@smu.edu	ehowell@smu.edu

A mathematics story problem's topic may influence how difficult it is to solve. For example, a student is more likely to accurately solve a story problem with a topic relevant his or her interests (e.g., a "personalized" scenario on playing video games) than a matched story problem that is not (Walkington, in press). Nathan, Kintch, and Young (1992) proposed a model of story problem solving where learners construct a mental representation of the actions and relationships in the problem, a *situation model*, which is then connected with formal mathematical operations. Problems with relevant and familiar topics, like personalized stories, may promote situation model construction by allowing new mathematics concepts to be connected to prior experience, with key concepts becoming more *grounded* (Goldstone & Son, 2005). Problems with relevant topics may also elicit *interest* in the content to be learned (Walkington, in press). However, individual-level personalization may not be feasible for a heterogeneous classroom (Hidi, 1990). Therefore, we identify topics that support problem-solving across a diverse sample of students.

We used LIWC, a dictionary-based computerized text analysis program that counts words in many categories. LIWC measured problem topic by determining the percentage of the words in a story problem that belong to different categories (e.g., social processes and work). We analyzed a dataset from a diverse array of secondary students ($N = 3394$) solving 282 traditional story problems on linear functions in Cognitive Tutor Algebra (CTA). CTA is an intelligent tutoring system that provides adaptive hints and logs student answers (Morgan & Ritter, 2002). After controlling for aspects of the problem's mathematical structure, we tested for associations between the topic of the story problem, accuracy, and hints requested. Words related to social processes (e.g., talk, husband, friend) were positively associated with correct answers ($\beta = .29$, $p < .001$) and negatively associated with hint-seeking ($\beta = -.04$, $p = .03$). In contrast, words related to work (e.g., job, business, profit) were negatively associated with correct answers ($\beta = -.26$, $p < .001$) and positively associated with hint seeking ($\beta = .29$, $p < .001$). Also, words related to food (e.g., restaurant, pizza, cook) were negatively associated with hint-seeking ($\beta = -0.10$, $p = .03$). Students' situation models appeared to be facilitated if the problem was about social processes and food and hindered if the problem was about work. Future research may illuminate whether this effect is due to increased familiarity with the topic or activated interest in the story problem.

Research findings on integrating visuals with text have indicated that students learn less when interesting but irrelevant materials, such as decorative images, are included (e.g., Harp & Mayer, 1998; Mayer, 2009; Sweller, 2005). The basic idea is that these can overload processing and disrupt student learning and performance, but evidence with math problems is mixed (e.g., Berends & van Lieshout, 2009). Based on the theories and previous research findings, we revised eight problems in an existing mathematics curriculum. We used four types of revisions within-subjects; three removed decorative images and one added relevant information to the visual.

Fifty seventh-grade students each completed eight problems. We assessed students' problem solving accuracy and strategies in addition to their math background, math attitudes, and contextual recall as these measures potentially influence the effect of visual representations. Revising the problems in concordance with the research-based principles did not have a consistent effect on performance or strategy use, nor were these effects related to students' math ability or anxiety. This is in contrast to what is often found in applications of these principles in science (see Mayer, 2009). Adding labeled dimensions to a visual increased the use of units, although not necessarily in a correct way. Of note, we found that the revisions did not affect students' opinions about the problems. The recall measures indicated that students encoded the contextual information from the text and/or visuals. Additional processing of the contextual information (as seen by correct recall) tended to be associated with lower mathematical accuracy, but this was unrelated to the presence of the decorative image. Overall, the lack of consistent effects indicates the need for further research on the influence of these principles in mathematics.

Given the multitude of visual representations in mathematics textbooks, it is critical to understand how visual information (both decorative and relevant) influences students' problem solving. The math ability level of our students was relatively high, and other individual differences may explain the lack of consistent effects. Investigating student attitudes as well as their contextual memory broadens the research base, so that researchers and educators can develop more nuanced understanding of the uses of visuals. Most clear from this research, however, is the need to further address how to enhance the integration of visual and verbal information in the mathematical problem solving of K – 12 students.

ALLOCATING OPPROTUNITY: DISBURSEMENT OF TITLE I FUNDS AND MATHEMTICS COURSE-TAKING AMONG SECONDARY STUDENTS

Kate M. Degner
University of Iowa
katherine-degner@uiowa.edu

Keywords: High School Education, Equity and Diversity

Public school children frequently take different courses, based on ability and interests. Recent national data show that low SES students enroll in rigorous coursework less frequently than their middle and upper class counterparts (Caro, McDonald, Willims, 2009; Tyson, 2011).

The Title I Program as part of the ESEA was created to provide financial assistant to schools serving large concentrations of children from low SES. van der Klaauw (2008) has shown that the use of Title I funds has done little to improve the academic achievement of low SES students. With the reauthorization of ESEA schools have more leeway in the way they spend their Title funds.

Purpose of the Study

The purpose of this study was to measure the impact that varied Title I spending may have among low SES students, in terms of level of mathematics courses taken in high school. The research question for this study is; Does the way Title I money is spent in a school influence the mathematics course-taking decisions of low SES high school students?

NAEP:09 mathematics achievement data and HSTS:09 were used to address this question. A t-test was used to compare mean level of mathematics course-taking for low SES students in schools who spend Title I funds differently.

Results

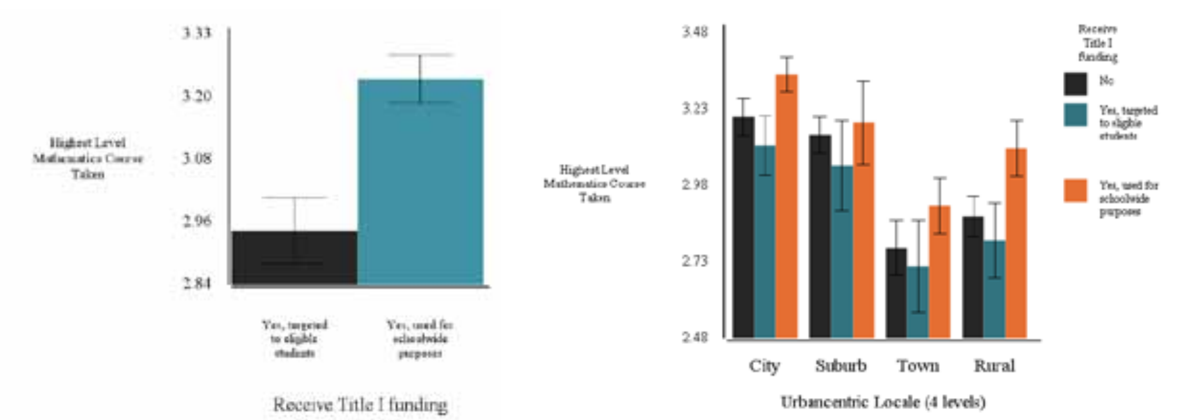

Figure 1: Course-taking Among Title I Students by Type of Title I Spending

RELIGIOUS PARTICIPATION AND MATHEMATICAL PROBLEM-SOLVING: THE RELATION BETWEEN RISK-TAKING AND PROBLEM CONTEXT

Tracy Dobie
Northwestern University
tdobie@u.northwestern.edu

Keywords: Problem Solving, Informal Education

Research has indicated that children think about mathematics problems differently and experience different levels of success, depending on the context in which problems are situated (Saxe, 1991; Taylor, 2009). However, there has been little exploration of the relation between problem context and *intellectual risk-taking* (IRT), or "engaging in adaptive learning behaviors (sharing tentative ideas, asking questions, attempting to do and learn new things) that place the learner at risk of making mistakes or appearing less competent than others" (Beghetto, 2009, p. 210). IRT also includes a willingness to participate when one does not fully understand the material (Boekaerts, 1993). Despite its potential to promote learning, cognitive development, and identity support, IRT is atypical in schools (Clifford, 1991; Streitmatter, 1997).

In this work, I examine IRT in interviews of 27 children (aged 5-12) whose families tithe (give 10% of their earnings to the church). I ask a) *How does placing a mathematics problem in a tithing-related context influence children's IRT?* and b) *What supports might facilitate IRT on tithing context questions?* Multiple questions were presented in two problem-solving contexts: *general* (e.g. What is 10% of 10?) and *tithing* (e.g. "Let's say you have $10 and you have to tithe at 10%. How much would you give to the bishop?"). Ethnographic observations of Sunday school classes were also conducted since all children interviewed attend these classes weekly.

Results indicate that children exhibited greater IRT - or willingness to offer answers, whether correct or incorrect - when problems were posed in a tithing context than a general context. Across all questions, children responded with a guess 96% of the time in the tithing context, compared to 63% in the general context. While many factors might contribute to this difference in IRT, I hypothesize that children appropriated risk-taking patterns from Sunday school, a setting associated with tithing. Ethnographic data identified four elements of Sunday school that create a culture of IRT: 1) *Guessing activities* encouraged participation prior to complete understanding; 2) Frequent *teacher questioning* encouraged children to share ideas, even with mistakes; 3) *Talks/ prayers* allowed children to challenge themselves by speaking in front of large groups; and 4) T*eachers supports*, such as whispering words in students' ears during talks, allowed children to engage in advanced tasks by lowering entry points and difficulty of material.

This study suggests that it is crucial for teachers and researchers to carefully choose the contexts used to present problems since problem context is related to IRT. Additionally, if risk-taking patterns in out-of-school settings can be activated by problem contexts, drawing on practices in which students typically take risks might be one way to encourage IRT in schools.

REPRESENTATIONS OF MATHEMATICS IN CHILDREN'S MEDIA

Jennifer Hall
University of Ottawa
jennifer.e.hall@uottawa.ca

Keywords: Affect, Emotion, Beliefs, and Attitudes; Elementary School Education

This poster session reports on a portion of a multifaceted research project that investigated elementary students' views of and experiences with mathematics and mathematicians, and the ways that students' views may be impacted by parents' views, teachers' views, and popular media representations of mathematics and mathematicians. The overarching goal of this project is to understand how outside sources can influence children's views. Prior research (e.g., Ma, 1999) has shown that negative attitudes toward mathematics are linked to decreased achievement and participation, but it is unclear what factors impact children's attitudes toward mathematics.

This study is framed with a feminist and social constructivist stance. As such, I conceive of views of mathematics, as well as mathematics as a discipline, as socially constructed and gendered. The conceptual framework for this study involves producers and active consumers. In an interaction, messages are disseminated by a producer (e.g., media) and received by a consumer (e.g., child). Each received message is actively evaluated by the consumer, who either alters the existing schema to include the new idea or discards it (Huntemann & Morgan, 2001).

The larger research project involved questionnaires, drawings of mathematicians, and focus group interviews with Grade 4 and 8 students from Ontario; interviews with teachers and parents; and an analysis of children's media. For the purposes of this poster session, I report on the media analysis. Media play a key socializing role in children's lives (Roberts & Foehr, 2004), so exposure to media messages about mathematics may impact students' views of mathematics.

To guide the media selection, a list of the 'top' children's media was compiled from students' responses to an online questionnaire in which 156 Grade 4 and 8 students took part. For each of five media types (television shows, movies, websites, video games, and books), participants listed their three top choices. From these data, a 'top choices' list was compiled, which was comprised of 10 television shows, three movies (or series), seven websites, six video games, and five books (or series). To narrow the viewing, summaries of each individual title (e.g., an episode of a television show) were read online; if there was any indication of mathematical content, the title was selected for analysis. Detailed notes were taken for each title viewed, and these notes were analyzed for mathematical content. Mathematics-related instances were summarized and themes were established for each series, for each media type, and across all media types.

Wide variations of mathematical content and messages were found to exist across media types, although stereotypes and mathematical errors were commonly featured. A full discussion of the findings will be presented in this poster session, with the findings positioned with respect to their potential impact on children's views of mathematics and mathematicians.

CONSTRUCTING NARRATIVES AROUND STEM ACHIEVEMENT AND MOTIVATION AMONG LEARNERS FROM NON-DOMINANT BACKGROUNDS

Victoria M Hand
CU-Boulder
victoria.hand@colorado.edu

Keywords: Equity and Diversity, Learning Theory, High School Education

Predominant narratives around STEM achievement—particularly in mathematics—often locate explanations for (un) successful experiences in schooling with an individual's motivation. These meta-narratives fail to account for the role of sociopolitical contexts in differences among opportunities for students from dominant versus non-dominant ethnic, racial and cultural backgrounds (Gutiérrez 2007). As mathematics learners from non-dominant backgrounds draw upon these ready-at-hand narratives to figure themselves within the world of mathematics education, they unwittingly participate in their own oppression (Bourdieu, 1991) This poster reports on research that examined narrative construction among underrepresented high school math and science students, and identifies features of this process that either reinforced or problematized the motivation-achievement narrative.

The study researched the question: *How do features of an activity system within which students construct narratives around achievement and motivation afford and constrain the nature of those narratives?* Narratives tend to oversimplify context in the process of identifying a "past", locating people, and putting them along a trajectory towards a future (Bamberg & Andrews, 2004). However, narrative construction is necessarily situated. Thus, analysis focus on what Ochs and Capps (2001) call dimensions of *lived narratives* such as: *tellability* (coherence and appeal of a story); *tellership* (type of involvement other people have in the narration); *linearity* (logical coherence); *embeddedness* (relation to theme and context); and *moral stance* (strength and focus). Positioning theory (Harre & Langenhove, 1999) was also utilized to attend to the way that students positioned themselves and "others" with respect to mathematics achievement and social and political processes. Desults from the study suggest that narrative construction that supports turn-taking among interlocutors, draws on everyday learning experiences, and that problematizes categories can disrupt the predominant narrative.

GENDER DIFFERENCES: EXAMINING SIXTH GRADE STUDENTS' UNDERSTANDING OF GEOMETRIC SPATIAL VISUALIZATION

Christa Jackson
University of Kentucky
christa.jackson@uky.edu

Jennifer Wilhelm
University of Kentucky
jennifer.wilhelm@uky.edu

Jeffrey Peake
University of Kentucky
jpe233@uky.edu

Keywords: Gender, Geometry and Geometrical and Spatial Thinking

Mental rotation is the ability to look at an object and visualize its rotation in three-dimensional space. Males, in general, have stronger spatial reasoning skills, and typically outperform their female counterparts on mental rotation tasks (Linn & Petersen, 1985). We contend students must have developed understanding in geometric spatial visualization in order to understand many astronomical concepts. The purpose of this study was to examine differences between two group of sixth grade students' geometric spatial reasoning and scientific content knowledge from pre to post implementation of an astronomy unit. Both student groups (Juniper Middle School: two experimental and one control; Butternut Middle School: three experimental and one control) studied Earth/Space concepts related to the Solar System. Students' geometric spatial content and scientific knowledge was documented before, during, and after project implementation, and their spatial and scientific understanding was assessed pre and post via survey instruments. The quantitative data sources included the Lunar Phase Concept Inventory (LPCI) (Lindell & Olsen, 2002); the Geometric Spatial Assessment, (GSA, Wilhelm et al., 2007); and the Purdue Spatial Visualization-Rotation Test (PSVT-Rot) (Bodner & Guay, 1997). For the purpose of this study, only the multiple-choice questions related to geometric spatial visualization were analyzed: LPCI (7), GSA (4) and PSVT-Rot (20). A RMANOVA was conducted with the factor being teacher, experimental/control group, and gender and the dependent variables for each factor being pre/post scores. As we compared males and females between and within the experimental and control groups at Butternut, we found experimental males and females achieved more significant gains from pre to post on geometric spatial visualization when compared to the control group. This can be attributed to teacher instruction and the implementation of the NASA-based curriculum. The NASA-based curriculum is designed to develop students' geometric spatial visualization through the use of 2D and 3D models, Stellarium (planeterium software), and moon journaling. At Juniper, the experimental males and females made significant gains, as well as the control males. Like Butternut, the gains for the experimental group can be attributed to teacher instruction and the NASA-based curriculum. However, the gains for the control males can be attributed to teacher instruction. The control teacher implemented more 2D and 3D models than the experimental teachers, and used Stellarium, and videos that enhanced students' spatial understanding. Understanding how *both* males and females developmental knowledge of spatial content differs may lead to knowing how to better support spatial reasoning for both genders.

DEVELOPING POSITIVE STUDENT-TEACHER RELATIONSHIPS IN STEM CLASSES

Kari Kokka
Harvard University
kari_kokka@mail.harvard.edu

Secondary school is full of marked changes for American students. Students experience school social environments at odds with their developmental needs, shuttling through multiple subject-specific classes threatening the quality of relationships with teachers and students' sense of support and relatedness (Eccles et al., 1993). Caring student-teacher relationships, where the teacher holds students to high expectations may be particularly important for youth of color in urban schools (e.g. Duncan-Andrade, 2009). However, student-teacher relationships are often most tenuous in public schools in urban settings (e.g. Fine, 1986). Perception of the level of teacher support is correlated to students' intrinsic value of mathematics (Midgley, Feldlaufer & Eccles, 1989). Because student-teacher relationships may impact student perceptions of teacher support, this research explores the nature of these relationships. Three STEM teachers from City Performing Arts Academy,[1] a public school in Boston, and their students were collaborators in this research. City Performing Arts Academy uses an Advisory system where every teacher serves as an Advisor for students' four-year high school careers. Advisory is a small class with the goal of promoting students' sense of belonging by attending to personalized academic and social emotional needs to improve education outcomes. Because Advisory intends to build a trusting student-teacher relationship to increase student engagement, this study investigated the nature of student-teacher relationships in Advisory and how they may differ and/or impact (positively or negatively) the relationship in STEM classes. Interviews with students included those who have their STEM teacher for both their STEM class plus Advisory as well as those who have their teacher just for STEM class (and not Advisory). Student interviews and participant observation revealed that students' relationship with their teacher in Advisory differed from and supplemented their relationship with their teacher in STEM class. Similarly, teachers' viewed their responsibilities as an Advisor as greater and more personal than that of teaching in STEM class. Both student and teacher perspectives suggest ways for STEM teachers to build positive relationships with students with or without Advisory class (e.g. by taking time after school to help with homework and supporting students with challenges outside of school.)

INTUITIONS IN MATHEMATICAL ACTIVITY: INSIGHTS FROM WORKPLACE TRAINING

Lionel LaCroix
Brock University, Canada
llacroix@brocku.ca

Chiara Andrà
University of Torino, Italy
chiara.andra@gmail.com

Lyndon Martin
York University, Canada
lmartin@edu.yorku.ca

Keywords: Learning Theory, Cognition, Affect, Emotions, Beliefs and Attitudes

Existing research on mathematical intuitions tends to focus on intuitions related to formal mathematics and to portray intuitions as tacit mental models in the minds of individuals (e.g., Fischebein, 1987). Starting from an interest in mathematics activity and learning outside of formal academic contexts and drawing on Fischbein (1987, 1998), Kant (1998), Radford (2009), and Roth and Radford (2011), we examine intuition within workplace training from a socio–cultural perspective and attempt to answer the question, *How are mathematical intuitions related to other dimensions of the cultural–historical activity within which they arise?*

Our research examines mathematical intuitions of three ironwork apprentices during a one hour collaborative problem solving activity recorded on video during the year-two college component of their apprenticeship program. At this point, each of the apprentices had approximately one year of trade experience. In the episode reported here, they were working to determine the weight of a four-beam assembly based on the lengths and beam gauge information—weight or mass per unit length in either pounds per foot or kilograms per meter—provided for each component on a set of technical drawings for a multi-story steel structure.

Central features of mathematical intuitions identified by Fischebein (1987), namely immediacy, self-evidence, globality, and coercieveness were evident in the apprentices' discourse and actions as they complete this task. Unlike Fieschbein (1989), however, we do not see intuitions predominantly as mental models in the minds of individuals. Our analysis revealed ways in which intuitions are: evidenced through the spontaneous enactment of gestures and thus embodied, reflective of prior cognitive experience (e.g., from school mathematics) and lived sensual experiences (e.g., with construction materials and artefacts on the job as an ironworker), shared by participants in common activity, and connected with emotions related to achieving the object or goal of an activity. Implications for mathematics teaching, learning, problem solving and further research are discussed.

The function concept is one which high school and undergraduate mathematics students' difficulties are well documented in mathematics education research. Functions are often seen as a gatekeeper in mathematics and have been given a significant focus in the Common Core Standards (2010). One of the most recent research trends attempting to support student learning in relation to function involves leveraging covariational and quantitative reasoning (Carlson et al., 2002; Smith III & Thompson, 2008). Unfortunately, several researchers (e.g., Smith III & Thompson, 2008) have illustrated that school mathematics does not include a foundational focus on covariational and quantitative reasoning. As a result, students often construct function meanings devoid of imagery that involves relationships between covarying quantities (see Oehrtman, Carlson, & Thompson [2008] for review). For instance, students conceive functions as a call to execute a calculation as opposed to a mapping between quantities' values.

In our poster, we contrast various approaches to function against the backdrop of quantitative and covariational reasoning. Using data we collected during clinical interviews with pre-service teachers at a large state institution in the Southeast United States, we draw attention to the role of these reasoning processes in conceiving functions and their inverses. For instance, our work suggests that typical approaches to teaching inverse lead to students engaging in repeated experiences devoid of quantitative reasoning. As a result, these students (who later become teachers) construct meanings that are not preparing them to support students in developing robust meanings for function. As another example, when posed with solutions that are quantitatively correct but non-canonical (e.g., graphing the variable *x* on the vertical axis), the pre-service teachers had difficulty attributing viable ways of thinking to the posed solution. Such an outcome illustrates that these pre-service teachers hold meanings that restrict their ability to interpret non-canonical but correct student work, which has significant implications for their teaching. We highlight such data and characterize implications relative to function, quantitative reasoning, and covariational reasoning.

LATINA/O MATHEMATICS STUDENTS' PERCEPTIONS OF INTERPERSONAL RELATIONSHIPS IN COLLEGE MATHEMATICS

Victoria R. Larabell
Purdue University
vpardo@purdue.edu

Keywords: Equity and Diversity, Post-Secondary Education

It is known that interpersonal relationships are significant to the success of the Latina/o mathematics learner (Gutierrez, 1999). Unfortunately, interpersonal relationships in mathematics are understudied (Hackenberg, 2010). For this reason, this study seeks to answer the following question: How do Latina/o mathematics students perceive their interpersonal relationships with their mathematics professors, peers in mathematics, and families with respect to mathematics and what impact do their views on these relationships have on their persistence in mathematics? To explore the role of such relationships in Latinas/os experiences in mathematics, I define a *meaningful relationship in mathematics education* (MRIME) as interactions between two parties in which one party acknowledges the other party as a sociocultural being and fosters their mathematics identity. This definition draws from research on care (Hackenberg, 2010; Noddings, 1988), mathematics identity and socialization (Martin, 2000) and mathematics students as sociocultural beings (Gutierrez, 1999).

This study was done using case studies. Four Latina/o students who were mathematics majors or had a bachelor's degree in mathematics were recruited using a Facebook page. The data collection took place over a period of one year. Three hour-long telephone interviews were conducted with each participant. Analysis of the interviews was based on identifying evidence of components of MRIME including the fostering of the participants mathematics identity and acknowledgement of the participant as social and cultural beings.

The results showed that the participants' views of their interpersonal relationships had a significant impact on their persistence in mathematics. For example, Sandy perceived her relationships with her professors, peers, and family as all meaningful. She felt that each of the three groups of people recognized her as a sociocultural being and helped her to develop her mathematics identity. Sandy ended up getting a master's degree in mathematics as a result. Sonya, on the other hand, viewed most of her interpersonal relationships in mathematics negatively and dropped out of mathematics by changing her major in her last year of college.

These results imply that MRIME is a sufficient framework for studying the interpersonal relationships of Latinas/os in mathematics. Also, they suggest that meaningful relationships are powerful influences on Latina/o mathematics students and their persistence in mathematics.

UNPACKING BROUSSEU'S DIDACTICAL MILIEU

Azita Manouchehri
The Ohio State University
Manouchehri.1@osu.edu

Dingding Huang
The Ohio State University
dinglei.huang@gmail.com

In this work we unpacked the construct of didactical milieu by examining ways in which interaction assisted in eliciting and evolving mathematical thinking of a child. The findings challenge the power relationship of knowledge, which is not only transferred from the more knowledgeable agent to the learner, but also conveyed from the learner to the more knowledgeable agent as guide for optimizing space of for productive didactical interactions.

Keywords: Cognition, Learning Theories, High School Education

Of particular interest to the research we will report was to identify ways in which "interaction" assisted in evolving children's mathematical thinking while engaged in solving mathematical tasks. Relying on Brauesse's Theory of Didactical Situations (1980) as a theoretical tool for grounding our methodology, and an analytical tool for interpreting interactions; we examined: *How does interaction influence mathematical practices of children?*

In analyzing the quality, content and nature of interactions and their influence on children's mathematical practice, we chose to rely on data from one specific interview (approximately 60 minutes) with one child (Dana-a pseudoname) as she was prompted to solve a pattern-generalizing task. At the time of the interview Dana was enrolled in 8th grade and taking Algebra I. This particular interview session was chosen deliberately since it provided persuasive illustrations of the impact of interactions on evolving practices of the child whilst highlighting the particular epistemological responsibilities and analytical demands that they placed on the interviewer when eliciting and responding to the child's mathematics, as previously articulated in Brousseu's theory of didactical situations. Data coding followed three stages. First, to break down the conversational exchanges and the moment-by-moment construction in the ongoing interactions, we conducted an analysis of language functions of verbal exchanges during the interview, according to turns and segments of utterances offered (Kovalainen and Kumpulainen, 2009). A second coding of data determined the specific mathematical actions or conceptual shifts that occurred during the interactive episode including both interactional agents (interviewer and Dana) as subjects of study. At the third stage, we clustered the segments according to the type of *situational* forms they seemingly resembled (Action, Formulation, Justification, Institutionalization).

A closer inspection of the participants' practices, collectively, revealed two distinct ways in which the interviewer impacted Dana's work: evoking reflection by eliciting reasoning and explaining, providing a structure to solidify theoretical knowledge through questioning and or collaboration. In turn, Dana's actions and mathematical observations forced shifts in the interviewer's position towards the task, creating a climate for collaborative mathematical sense-making.

Student engagement in mathematics classrooms can depend on many variables, including peer interactions and social contexts (Middleton & Jansen, 2011; Goldin *et al.*, 2011). When students work in groups, some may be more vocal, while others may say little if anything. This paper focuses on a group of students in which one girl ["Jen"] seemed to refrain from talking to her peers over the entire course of a teaching unit (8 sessions over 2 1/2 weeks), because, in her own words, she "wanted to stay out of trouble." The research question we address is: How does Jen's interaction with her peers impact her mathematical engagement and learning."

We examine Jen's engagement using the concept of "engagement structures" – which are idealized, identifiable, recurring, highly affective patterns in individual students, inferred from observed behaviors, interviews and responses to questionnaires. Our data include videotaped classroom sequences, responses to an engagement survey, mathematical pre- and posttest data, and results from retrospective stimulated-recall interviews. Our analysis indicates that Jen was both unsure of her own mathematical ability, and determined to avoid confrontation with her peers and/or the teacher. She opted to refrain from engaging in conversation with peers, neither asking nor answering questions (posed by peers or the teacher). She demonstrated many of the characteristic behavior patterns associated with the "Stay Out of Trouble" engagement structure. In this structure, as described in Goldin *et al*. (2011), a student desires to avoid interactions that may lead to conflict (e.g., a fight) or distress (e.g., embarrassment, humiliation, or anger) involving peers or someone in authority. Avoidance behavior, including striving not to be noticed, may supersede addressing the task's mathematical content.

Despite her avoidance of peer interactions, our data indicate that Jen appeared to always pay close attention to all of the mathematical activity that took place. Further, while she scored the lowest of all the participants on the math pre-test, Jen ended up with the highest score increase in the study based upon her post-test results. Moreover, in a math task-based interview, she demonstrated a very strong knowledge of the mathematics that was covered.

One main conclusion, which of course requires further study, is that it is important to broaden our perspective on the role and nature of mathematical engagement. Jen's engagement patterns appeared to be *highly complex* and *situation-dependent*, and not readily summed up on a linear scale. Further, Jen's "Stay Out of Trouble" pattern appears to have some *adaptive value* in relation to her learning of the mathematics.

RELATIONSHIP BETWEEN NEGATIVE ATTITUDES TOWARD MATHEMATICS AND COLOMBIAN CHILDREN'S MATHEMATICS ACHIEVEMENT

Yenny Otalora
University of Massachusetts, Dartmouth
yotalorasevilla@umassd.edu

Keywords: Advanced Mathematical Thinking; Affect, Emotions, Beliefs and Attitudes

This study investigated the association between negative attitudes toward mathematics and mathematics achievement in 4th-grade Colombian children (*M*=10.4 year-old), using the large-scale data source Trends in International Mathematics and Science Study-TIMSS 2007. Scores in the mathematics test were the measure of mathematics achievement. Two indicators of negative attitudes toward mathematics were the independent variables: (a) *Mathematics is boring* and, (b) *Mathematics is harder for me than for others*. These are statements about mathematics presented to students on a Likert-type scale with four levels of response: Agree a lot, agree a little, disagree a little and disagree a lot. Students in each level were deemed as the conditions of each variable. Findings showed that scores in the Mathematics test increase as the level of agreement with both statements *Mathematics is boring* and *Math is harder for me than for others* decrease (Table 1).

Table 1: Average Scores in Mathematics Test for Degree of Agreement with Statements

	Mathematics is boring			Math is harder for me than for others		
	N	*Mean*	*SD*	*N*	*Mean*	*SD*
Agree a lot	615	329.9	82.5	1273	345.03	82.9
Agree a little	738	349.4	90.5	1310	365.02	84.2
Disagree a little	439	370.3	92.4	637	385.6	89.8
Disagree a lot	2413	393.2	80.3	1149	402.01	85.5

A one-way analysis of variance (ANOVA) indicated that the degree of agreement with the statement *Mathematics is boring* is significantly associated to the students' performance on the test, $F(3,4201) = 120.65$, $p < .001$, eta-squared = .08, $r = .28$, representing a middle-sized effect. Polynomial analyses showed a significant linear trend, $F(1, 4201) = 361.631$, $p > .001$, eta-squared = .08, $r = .28$, middle-sized effect. As the degree of agreement with this statement decreases, the means increase proportionately. A one-way analysis of variance (ANOVA) indicated that the degree of agreement with the statement *Mathematics is harder for me than for others* is also significantly related to students' outcomes on the test, $F(3,4365) = 98.85$, $p < .001$, eta-squared = .06, $r = .25$, middle-sized effect. Polynomial analyses showed a significant linear trend, $F(1, 4365) = 294.59$, $p > .001$, eta-squared = .06, $r = .25$, middle-sized effect. As the level of agreement with this statement decreases, the means increase proportionately. These findings have strong implications to educational practice and curriculum (Ma and Xu, 2004).

'VALUE CREATION' THROUGH MATHEMATICAL MODELING: STUDENTS' MATHEMATICAL DISPOSITION AND IDENTITY DEVELOPED IN A LEARNING COMMUNITY

Joo young Park
Teachers College, Columbia University
jp2902@columbia.edu

Keywords: Modeling, Instructional Activities and Practices, Affects

Studies reported that most students perceive mathematics as an impediment of their success in school and barely see the value of learning mathematics in life (e.g., Ernest, 1994). It becomes a question of what learning environment enables students to engage in meaningful mathematics learning and develop positive disposition as well as self-concept. Existing literatures demonstrated that modeling tasks allowed students to appreciate the relevance and usefulness of mathematics to individuals as well as to society (Blum & Niss, 1991; Boaler, 2002). The purpose of this research is to examine how mathematical modeling activities within a collaborative learning community impact on students' perceived 'value' of mathematics. The concept of 'value' was adopted from Makiguchi's theory of "value creation"(Bethel, 1989, p6).'Value creation' concerns with human development that enables individuals to gain benefits from developing a relationship with the object (mathematics) not only at personal level but also at societal level. With respect to value of learning mathematics, researchers introduced "productive disposition"(NRC, 2001, p131) and "mathematical disposition"(NCTM, 1989, p1) as an indicator of students' appreciation of the role and value of mathematics. With a unified framework of the theory of 'value', mathematical disposition, and identity, this study identified the elements of the value-beauty, gains, and social good-with the observable evidences of mathematical disposition and identity.

A total of 60 students who enrolled in a college algebra course participated in 'LifeStyle' mathematical modeling project within a group. A mixed method approach was used for data collection and analysis in this study. The result of a two-sample t-test showed the significant changes in students' mathematical disposition between pre and post survey. Based on questionnaires, surveys, and observations data, fifteen focal students were selected for interviews. Interview data supported the evidence of how students' perceived value-beauty, benefits, and social value-has been changed while engaging in the modeling activities with peers in a group.

Much work on mathematical transitions has focused on challenges presented by differences in curricular materials and instructional strategies (e.g., Jansen, Herbel-Eisenmann & Smith, 2012), while transitions work outside mathematics has focused on socio-emotional experiences (e.g., McDermott, Watkins, Rovine & Rikoon, 2013). This poster links these two analyses by looking broadly at transitions across grade levels to consider the ways that socio-emotional experiences impact participation in mathematics.

In this analysis, we rely on positioning theory to explain the ways in which people are constructed differently in different contexts as a result of "positioning by whatever powerful discourses they happen to encounter" (Holland, Skinner, Lachiotte & Cain, 1998, p. 27). We augment this work with Latour's actor-network theory, which directs attention not only to the ways that interactions among human beings shape each other, but also to the ways that physical objects (books, toys, tables, etc.) shape human experiences.

For this project, we analyzed the experiences of four students over three years of mathematics learning. All four students (two boys and two girls) were African American and attended a rural school that serves low-income families. We began observing these students in prekindergarten, videotaping both formal mathematics lessons and math-related play. We continued to videotape mathematics lessons throughout kindergarten and first grade. In addition, we conducted individual mathematics assessments at the end of each year, organized and documented parent math nights after school, and held focus groups and individual interviews with parents. During the first grade assessments, we also interviewed the children about their experiences in math classes and in the school broadly.

While our analysis is still in the preliminary stages, we have found that the difficulty of students' transitions was closely related to how students were positioned as mathematics students and as learners in general. For example, as students lost freedom to move about the room as they got older, they expressed distress in a variety of ways that impacted their participation in mathematics. In addition, students identified by a particular teacher as having behavior problems spent large sections of the school year isolated in their desks, which impacted the ways in which they could participate in mathematics. One surprise was that some children's positioning as "good" or "difficult" was quite fluid across the three years. Transitions marked as difficult – either in interviews or through the observation of behavior including crying and outbursts – seemed to relate as much to changes in the amount of movement permitted and to the ways the student was positioned by the current teacher as to either the mathematics curriculum or pedagogy.

PERCEPTIONS OF K-16 MATHEMATICS EDUCATION FROM 'LA FRONTERA': A QUALITATIVE STUDY OF MEXICAN-AMERICAN POSTESECONDARY STUDENTS

Carlos Paez
University of Texas at El Paso
crpaezpaez@miners.utep.edu

Judith H. Munter
University of Texas at El Paso
jmunter@utep.edu

Olga Kosheleva
University of Texas at El Paso
olgak@utep.edu

The purpose of this study is to investigate the non-mathematical factors, such as teacher beliefs and student attitudes that influence diverse postsecondary students' learning experiences in mathematics. The study examines Mexican-American students' perceptions about mathematics instruction in the U.S. formal education (K-16) system. The majority of Latino students in U.S. higher education today start their postsecondary education experience in a community college (Green, 2006). When these students complete high school, test scores indicate that many are not "college-ready" (Flores, 2007), and community colleges provide an excellent starting point for these students for several reasons.

The first stages of the study are framed mainly by constructionism, contructivism, and critical race theory (CRT). Constructionism is based on theories very similar to constructivism, however while constructivism places the main focus on the development of individual and isolated knowledge structures (Dubinsky & McDonald, 2001), constructionism focuses on the connected nature of knowledge with its personal and social dimensions (Kafai, 2006). Critical race theory (Hylton, 2012) focuses on issues of equity, desconstructing power relationships in schools and society. Constructionist scholars describe authentic practices within schools that help students to develop new knowledge based on their prior knowledge. These authentic practices allow students to engage in authentic learning experiences through meaningful activities.

This qualitative research study uses purposeful sampling consisting of a sample selection procedure, based on the researcher's knowledge and experience of the group to be sampled using clear criteria to guide the process. Then, the researcher administered an on-line survey to all students that decide to attend the free interactive technology sessions. The next stage consists of in-depth interviews with a smaller sample of self-selected students. The transcriptions of the were coding for theoretical meaning (Charmaz, 2006). Grounded theory methods provide a unique approach to capture informants' reflections about issues in mathematics education.

This study contributes to existing knowledge about non-mathematical factors that impact student attitudes, teacher beliefs relative to the mathematics education in the U.S. public school system. This knowledge has implications for policymakers, researchers and practitioners to broaden perspectives on mathematics thinking and learning in the 21st century.

COLLABORATION, BEHAVIOR, AND AFFECT IN A GAME-BASED LEARNING ENVIRONMENT

Carmen Smith
University of Vermont
Carmen.smith@uvm.edu

Keywords: Middle School Education, Rational Numbers, Technology

Collaborative activity during game play is instrumental to learning (Stevens et al., 2008), and it is important for developing mathematical reasoning (Phelps & Damon, 1989). Yet, the majority of mathematics games are designed for single players, which could make it less likely for students to learn from each other while playing. In this poster, we present a pilot study examining middle school students playing an online, single-player fraction game called Refraction both individually and in pairs. Refraction is a puzzle game requiring a combination of spatial reasoning and fraction understanding. Players split laser beams into appropriate fractions needed to power space ships stuck in space. We compared students' behavior and affect while playing alone and playing with a partner.

Fourteen seventh grade students played Refraction once a week for thirty minutes over the course of four weeks. While students were playing, we used the Baker-Rodrigo Observation Method Protocol (BROMP 1.0) to collect data on students' behavior and their affective states (Ocumpaugh, Baker, & Rodrigo, 2012). Two researchers made observations every twenty seconds of individual students' behavior and affect. They determined whether a student was silently playing the game, giving another student help, receiving help from another student, discussing the game, or off task. They also recorded whether the student was concentrating, delighted, confused, bored, frustrated, or experiencing a moment of eureka.

During the first game play session, students took a fraction pre-test and played the game individually. The following two sessions students played the game with a partner sharing a computer. During the last session, students took a post-test and played the game individually.

We found that students behaved differently depending on if they were playing individually or with a partner. There was a significant increase in the proportion of giving and receiving help from the first individual play session to partner play, and interestingly, giving and receiving help remained high when the students returned to playing individually in the last session. In other words, once students were put in a situation where needed to collaborate, they continued to do so even when returning individual play. We also found no differences in the level of collaborative activity for students who had different levels of fraction understanding on the pre-test. In this poster, a further exploration of the students' behavior and affective states will be discussed.

Keywords: Algebra and Algebraic Thinking, Instructional activities and practices

Flexibility in mathematics problem solving is an important skill for students (Woodward et al., 2012). Flexibility refers to the ability to solve mathematics problems in multiple ways and know when it is most appropriate to apply particular solution methods for a given problem (Star & Rittle-Johnson, 2008). The goal of the present analysis was to learn more about important factors associated with students' school year gains in flexibility in algebra.

Data for the study was taken from teachers and students using researcher-created Algebra I supplemental curriculum materials that focused on explicit comparison of side-by-side worked example pairs. We compared students' flexibility gains for the upper (n = 10) and lower quartile (n = 10) of teachers (*high flexibility teachers* and *low flexibility teachers*, respectively).

Results suggest that high and low flexibility teachers were not reliably different on any demographic variables. However, high flexibility teachers generally had younger students, were more likely to teach middle school classes, and had classes with significantly lower flexibility scores at pre-test. High flexibility teachers exposed their students to significantly more of the Algebra I intervention materials, both by using the materials more often (i.e., dosage) and using them for a greater percentage of their instructional time. Using video data, 3 high and 3 low flexibility teachers were compared on the types of questions they asked students. Both high and low flexibility teachers tended to ask more *why* questions when using the materials (treatment videos) compared to instruction without the materials (general videos). However, high flexibility teachers tended to ask more *open-ended* questions when using the materials, such as "So what's the general rule?" and "What did you just learn from this?".

This analysis suggests that frequent and extended exposure to materials that explicitly promote flexibility appear to make the most impact on flexibility gains. Moreover, when teachers ask students to verbalize what they learned (e.g., by using open-ended questions), students may benefit more from such materials. Further study is needed to get a more nuanced understanding of these findings, in order to better understand the ways in which teachers' implementation and enactment of the curriculum materials impacted student learning. Such an analysis is underway.

MIDDLE SCHOOL TEACHERS' UNDERSTANDING OF COGNITIVE DEMAND

Mourat Tchoshanov
University of Texas at El Paso
mouratt@utep.edu

Angelica Monarrez
University of Texas at El Paso
amonarrez5@miners.utep.edu

Keywords: Cognition, Middle School Education, Teacher Knowledge

This study examines middle school in-service teachers' understanding of cognitive demand. N=20 teachers from a number of urban middle schools at the Southwestern USA participated in the study as part of their professional development activities.

According to Smith and Stein (1998), "tasks that ask students to perform a memorized procedure in a routine manner lead to one type of opportunity for student thinking; tasks that require students to think conceptually and that stimulate students to make connections lead to a different set of opportunities for student thinking" (p. 269). This study focuses on Stein et al. (2000) cognitive demand framework. The framework separates low-level from high-level cognitive demands where memorization and procedures without connections fall at the low-level and procedures with connections and doing mathematics are at the high-level. Our research questions are the following: (1) Are middle school mathematics teachers able to recognize different levels of cognitive demand when presented by different tasks? (2) What are middle school mathematics teachers' rational and reasoning to identify different levels of cognitive demand? (3) To what extent are middle school mathematics teachers able to construct tasks at the different levels of cognitive demand?

We designed the following instruments to address the research questions:

1. Cognitive Demand Recognition (Measure 1). The purpose of this measure is to examine weather teachers recognize tasks at different cognitive levels. They were presented with four different problems involving the concept of similarity and were asked to rate the cognitive demand level necessary to solve the task. Teachers also provided a short rational for the rating.

2. Challenge Recognition (Measure 2). The second measure was presented as a task to derive the Pythagorean Theorem using the idea of similarity. After solving the task teachers were asked to rate the task according to the level of challenge on a scale from 1-5 where 1 is the lowest challenge and 5 is the highest challenge. The purpose of this task is to examine teachers' recognition of the link between cognitive demand and the level of challenge.

3. Task Construction at Different Levels of Cognitive Demand (Measure 3). This measure addresses the third research question. The purpose of this measure is to investigate whether the teachers were able to design tasks for their students at the different cognitive levels using the topic of area of a circle.

The result of the study showed that teachers are capable to recognize levels of cognitive demand and challenge of the presented tasks. However, participants had difficulty in constructing tasks at different levels of cognitive demand, most specifically, in distinguishing between tasks focused on procedures without connections and tasks that require connections among procedures. The study also presents the contextual categories teachers used in constructing tasks.

COGNITIVE TUTORING SOFTWARE IN BASIC MATH COURSES: BROADENING PERSPECTIVES ON MATHEMATICS THINKING AND LEARNING

Julian Viera
University of Texas El Paso
jviera1@utep.edu

Olga M Kosheleva
University of Texas at El Pasi
olgak@utep.edu

Judith Hope Munter
University of Texas at El Pasi
jmunter@utep.edu

A critical issue facing educators today is the large numbers of students required to take developmental math upon entering college due to traditional approaches to mathematical teaching and learning.

Cognitive Tutoring Software: ALEKS

Assessment and LEarning in Knowledge Spaces (ALEKS) is based on Knowledge Space Theory, a formal framework for assessment of knowledge (Flamagne, & Doignon, 2011). The purpose of this study is to determine whether the use of ALEKS in basic math courses helps entry level college students broaden their perspectives in mathematics learning. ALEKS uses adaptive questioning to accurately determine what a student knows and doesn't know in a course. Students practice, are assessed then repeat this process until they have mastered all or most of the concepts in a particular course.

Research on Broadening Students Perspectives on Math

Research on Developmental Math and Pre-calculus have found that the use of ALEKS has not only improved students test scores on the ACT and Accuplacer (Hagerty, $ Smith, 2005) and also improved students attitudes towards math learning. These studies found that the amount of time spent on ALEKS along with immediate face-to-face tutoring contributed to success in pass rates. Students also felt that ALEKS positively impacted their grade (Hampikian, Guarino, Chyung, Gardner, & Pyke, 2006).

Research in Progress

The researcher has worked with ALEKS over the last two years and has found that students working with peer tutoring showed greater weekly progress when compared to fully online classes. A traditional lecture was not required since students are in different knowledge spaces. ALEKS students have a higher pass rate in subsequent courses compared to non ALEKS students. The doctoral research proposal in progress is a mixed methods study, including pre and posttests (quantitative) and qualitative components (e.g., surveys, interviews, focus groups, observations) to determine effectiveness and impacts on student affect, emotions, and attitudes about mathematics thinking and learning. Preliminary qualitative and quantitative data will be presented for discussion.

DESIGN-BASED RESEARCH, REPRESENTATIONS, AND LEARNING TRAJECTORIES: THE CASE OF FRACTION MULTIPLICATION

Rozy Vig
Harvard University
rozy_vig@harvard.edu

Fractions, as a K-12 curriculum topic, are considered the most challenging to learn, difficult to teach, and essential to later success in mathematics (Lamon, 2007). Area models and numbers lines are two common representations used to support student understanding of fractions (Izsak, 2005; Saxe et. al., 2010). The challenge lies in extending the use of these representations to foster student understanding of fraction operations, such as, fraction multiplication (Charalambous & Pitta-Pantazi, 2006). When working with whole numbers, multiplication is often interpreted as repeated addition. Given 2/3 x 1/2, what does it mean to add 2/3 to itself 1/2 times? To support a more robust interpretation for fraction multiplication, multiplication as stretching and shrinking, we designed a learning environment centered on the Area Model for Fraction Multiplication (AM-FM) representation, a computer-based tool that combines area model and number line representations (Figure 1).

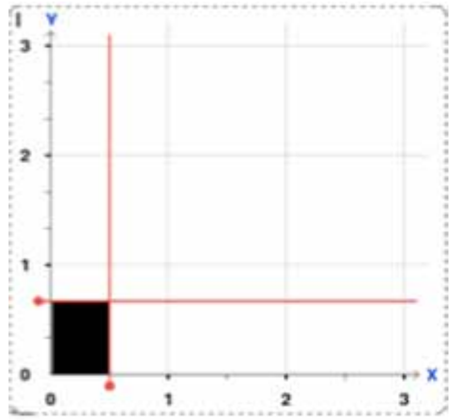

Figure 1a. The axes are partitioned into halves and thirds and the red marker lines are moved to x=1/2 and y=2/3.

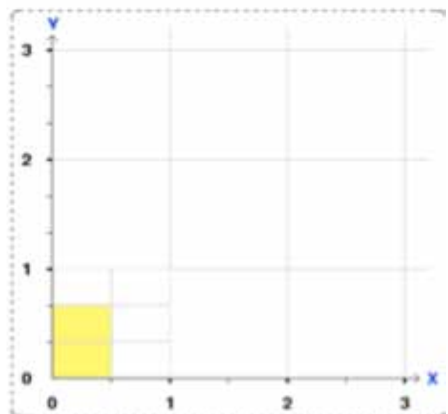

Figure 1b. The final area is tiled depicting in an area model representation of 2/6.

Figure 1. 2/3 x 1/2

We use design-based research to guide the development of the AM-FM representation and our theory about students learning trajectories specific to the designed learning environment. We present a single case study of knowledge growth and change, which supports our hypothesized learning trajectory and highlights the context sensitivity of knowledge coordination across the area model and number line features of the AM-FM representation. We end with implications for revision to the learning environment and to our local theory on student learning trajectories for fraction multiplication.

A LEARNING TRAJECTORY FOR DIRECTIONAL DERIVATIVE

Eric Weber
Oregon State University
Eric.Weber@oregonstate.edu

Keywords: Cognition, Post-Secondary Education, Learning Trajectories (or Progressions)

Models in physics, engineering, economics and mathematics inevitably involve reasoning about changes among many variables in a system. Students must grapple with the meaning of "varying the input" when there are two independent variables and determine rates when there is no natural direction or path in which change happens. However, little is known about what understanding(s) of rate of change of a single variable function allow students to conceive of the necessity of direction and path in interpreting and measuring rate. The purpose of this paper is to propose what I call the *two-change problem* as an important cognitive obstacle that students experience as they conceive of direction and path of rate of change.

Students must see their conceptions of rate of change in the plane as insufficient to describe a system in which at least three quantities are varying. Put another way, they must conceive of direction and path as *necessary* to quantify how fast a function is changing with respect to two or more arguments. Based on ten clinical interviews with both single and multivariable calculus students, I hypothesized that the students could be accomplished by the students' noticing that if a one quantity depends on at least two independent quantities; there are two rates of change occurring. I made this hypothesis because I found students' natural inclination when describing a rate of change is a single value that describes how fast the function is changing. However, often their first observation of a two-variable function at the same time they notice that the dependent quantity [f(x,y)] is changing with respect to both x and y. Thus, when there is a change in f, there can be a change in *both* independent quantities. For instance, a number of students noted in the interviews that if there is a change in both x and y, then it is plausible that there are two rates of change. However, at this point students often do not conceive of the x or y axis as a direction itself. However, as students grappled with how to form a "single" rate of change in three dimensions they puzzled over how to account for the changes in x and y. Initially students in the interviews suggested that the changes in x and y could be chosen independently of each other but some students insisted that the changes must be dependent or "there could be a million different rates of change". Indeed, the dependence of the changes in x and y specifies the direction vector in which the rate of change is considered in three-space. The independence or dependence of these changes is the core of the *two-change* problem.

Every student in the interview encountered this issue yet few could resolve it. Those who noticed the changes in x and y could not be chosen independently of each other without generating an infinite number of possibilities for the measurement of the rate of change of the function. They were able to then conceive of a fixed relationship between the changes in x and y as specifying a direction or path.

DEVELOPING MATHEMATICAL KNOWLEDGE FOR TEACHING THROUGH MENTOR-GUIDED LESSON STUDY

Kristen Bieda
Michigan State University
kbieda@msu.edu

Jillian Cavanna
Michigan State University
cavannaj@msu.edu

Xueying Ji
Michigan State University
jixueyin@msu.edu

Field experience can be a rich site for prospective teachers to develop the knowledge and skills they need for effective teaching, however little is known about how structures for supporting interactions between mentor and prospective teachers can maximize prospective teachers' learning. Lesson study has been shown to enhance practicing teachers' mathematical knowledge for teaching through collaborative inquiry with their peers. In this paper, we discuss the use of mentor-guided lesson study to support mentor and prospective teachers' collaboration in the field and provide evidence showing its potential to strengthen prospective teachers' mathematical knowledge for teaching. We will also share insights from the field for those interested in implementing this activity in teacher preparation coursework.

Keywords: Teacher Education-Preservice, Mathematical Knowledge for Teaching, High School Education, Lesson Study

Background

The apprenticeship structure known as "student teaching," "field experience," or "internship" is a universal part of teacher preparation, in both traditional and alternative certification pathways. Teachers often cite the field experience as the most valuable part of teacher preparation (Lortie, 1975). Over 1,400 institutions of higher education require completion of a student teaching experience for teacher candidates and 39 states in the U.S. have set minimum requirements for the length of the student teaching experience (NCTQ, 2011). Given the importance of field experience in teacher preparation, it is surprising that research on what prospective teachers learn in the field, as well as aspects that promote productive relationships between mentor and novice teachers, is so scarce (Wilson, Floden & Ferrini-Mundy, 2001). Existing research has predominately investigated how field experiences influence novice teachers' beliefs about teaching, but more research is needed to learn about *what* knowledge and skills novice teachers are learning through field experiences.

One type of knowledge, that field experiences may provide rich opportunities for prospective teachers to develop, is *mathematical knowledge for teaching* (Ball & Bass, 2003). Ball, Thames and Phelps (2008) define MKT as the "mathematical knowledge needed to perform the recurrent tasks of teaching mathematics to students" (p. 399). Over the past decade, much attention has been placed on the role of MKT in understanding the knowledge, skills, and dispositions needed for mathematics teachers to engage in ambitious practice. Lampert and Graziani (2009) define ambitious practice as mathematics instruction that provides all students with an opportunity to develop multifaceted knowledge of mathematics, participate in discussions about mathematical ideas, and solve authentic problems. Prospective teachers need opportunities to develop and deepen MKT if they are to enact ambitious practice.

For prospective secondary teachers of mathematics (PST-Ms), the mathematics coursework required as part of a teacher certification program can offer opportunities to deepen subject matter knowledge. However, these content courses are not designed to develop other aspects of

MKT, such as *knowledge of content and teaching* (KCT), which Hill et al. (2008) describe as the knowledge needed to select an appropriate representation to highlight key concepts in a mathematical investigation or choosing effective instructional examples. Opportunities to develop aspects of MKT such as KCT and KCS (*knowledge of content and students)* may occur in mathematics pedagogy coursework and in field experiences. One experience that has been shown to promote teachers' MKT is lesson study, a particular form of collaborative action research (Fernandez, 2005). The purpose of this paper is to share findings from an investigation into the potential for *mentor-guided lesson study*, where a mentor teacher collaborates with PST-Ms to do lesson study cycles, to support growth in PST-Ms' MKT. Specifically, we will discuss findings to address the following questions: *To what extent does mentor-guided lesson study promote prospective teachers' reflections on teaching related to their MKT? How does a mentor's prior experience in doing lesson study contribute to the development of prospective teachers' MKT during cycles of mentor-guided lesson study?*

Theoretical Framework
