Peer Review Process: Proceedings of the 8th Workshop on Innovative Use of Natural Language Processing for Building Educational Applications is a double-blind peer-reviewed topical journal.

This manuscript is an early draft of a paper published in IJT and thus may differ slightly from the final published version. Please see below for the official paper:

The research reported here was supported by the Institute of Education Sciences, U.S. Department of Education, through Grant R305F100005 to the Educational Testing Service as part of the Reading for Understanding Research (RFU) Initiative.
Abstract

We introduce a cognitive framework for measuring reading comprehension that includes the use of novel summary-writing tasks. We derive NLP features from the holistic rubric used to score the summaries written by students for such tasks and use them to design a preliminary, automated scoring system. Our results show that the automated approach performs very well on summaries written by students for two different passages.

1 Introduction

In this paper, we present our preliminary work on automatically scoring summarization tasks that are designed to measure global reading comprehension skills of students from grades 6 through 9. We first introduce our underlying reading comprehension assessment framework (Sabatini, O’Reilly & Deane, in press, Sabatini & O’Reilly, in press) that motivates the task of writing summaries as a key component of such assessments in §2. We then describe the summarization task in more detail in §3. In §4, we describe our approach to automatically scoring summaries written by students for this task and compare the results we obtain using our system to those obtained by human scoring. Finally, we conclude in §6 after a brief discussion and an outline of future work.

2 Reading for Understanding Framework

We claim that to read for understanding, readers should acquire the knowledge, skills, strategies, and dispositions that will enable them to:

• learn and process the visual and typographical elements and conventions of printed texts and print world of literacy;
• learn and process the verbal elements of language including grammatical structures and word meanings;
• form coherent mental representations of texts, consistent with discourse, text structures, and genres of print;
• model and reason about conceptual content;
• model and reason about social content.

We claim that the ability to form a coherent mental model of the text that is consistent with text discourse is a key element of skilled reading. This mental model should be concise, but also reflect the most likely intended meaning of the source. We make this claim since acquiring this ability:

1. requires the reader to have knowledge of rhetorical text structures and genres;
2. requires the reader to model the propositional content of a text within that rhetorical frame, both from an author’s or reader’s perspective; and
3. is dependent on a skilled reader having acquired mental models for a wide variety of genres, each embodying specific strategies for modeling the meaning of the text sources to achieve reading goals.

In support of the framework, research has shown the ability to form a coherent mental model is important for reading comprehension. For example, Kintsch (1998) showed that it is a key aspect in the process of construction integration and essential to understanding the structure and organization of the text. Similarly, Gernsbacher (1997) considers mental models essential to structure mapping and in bridging and making knowledge-based inferences.

2.1 Assessing Mental Models

Given the importance of mental models for reading comprehension, the natural question is - how does one assess whether a student has been able to build such models after reading a text. We believe that such an assessment must encompass asking a reader to (a) sample big ideas by asking them to describe the main idea or theme of a text, (b) find specific details in the text using locate/retrieve types of questions, and (c) bridging gaps between different points in the text using inference questions. These three types of questions are necessary to infer the structure of the reader’s mental representation of the text. In addition, we claim that it is also important to develop questions that tap how the key concepts and the supporting details for each concept are inter-
Although all these questions can be instantiated as multiple-choice questions, existing research indicates that a better alternative is to ask the reader to write a brief summary of the text instead. Yu (2003) states that a good summary can prove useful for assessment of reading comprehension since it contains the relevant important ideas, distinguishes accurate information from opinions, and reflects the structure of the text itself. More specifically, having readers write summaries is a promising solution since:

- it has considerable empirical support that it both measures and encourages reading comprehension and is an effective instructional strategy to help students improve reading skills (Armbruster et al., 1989; Bean and Steenwyk, 1984; Duke and Pearson, 2002; Friend, 2001; Hill, 1991; Theide and Anderson, 2003);
- it is a promising technique for engaging students in building mental models of text; and
- it aligns with our framework and cognitive theory described earlier in this section.

However, asking students to write summaries instead of answering multiple choice questions entails that the summaries must be scored and assigned a grade. Asking human raters to score these summaries, however, can be time consuming as well as costly. A more cost-effective and efficient solution would be to use an automated scoring technique using machine learning and natural language processing. We describe such a technique in the subsequent sections.

3 Summary Writing Task

Before describing the automated scoring approach, we describe the details of the summary writing task itself. The summarization task is embedded within a larger reading comprehension assessment. As part of the assessment, students read each passage and answer a set of multiple choice questions and, in addition, write a summary for one of the passages. An example passage and the summary writing instructions can be seen in Figure 1. Note the structured format of summary that is asked for in the directions - the first sentence of the summary must be about the whole passage and the next three should correspond to each of the paragraphs in the passage. All summary tasks are structured similarly in that the first sentence should identify the “global concept” of the passage and the next three sentences should identify “local concepts” corresponding to main points of each subsequent paragraph. Each summary written by a student needs to be scored according to a holistic rubric, i.e., a set of scoring criteria that assign grades to summaries based on holistic criteria rather than criteria based on specific dimensions of summary writing. The grades are assigned on a 5-point scale which are defined as:

Grade 4: summary demonstrates excellent global understanding and understanding of all 3 local concepts from the passage; does not include verbatim text (3+ words) copied from the passage; contains no inaccuracies.
Grade 3: summary demonstrates good global understanding and demonstrates understanding of at least 2 local concepts; may or may not include some verbatim text, contains no more than 1 inaccuracy.

Grade 2: summary demonstrates moderate local understanding only (2-3 local concepts but no global); with or without verbatim text, contains no more than 1 inaccuracy; OR good global understanding only with no local concepts.

Grade 1: summary demonstrates minimal local understanding (1 local concept only), with or without verbatim text; OR contains only verbatim text.

Grade 0: summary is off topic, garbage, or demonstrates no understanding of the text; OR response is “I don’t know” or “IDK”.

Note that students had the passage in front of them when writing the summaries. In addition, the rubric states that students should not be penalized for poor spelling or grammar in their summaries. In the next section, we describe a system to automatically score these summaries.

4 Automated Scoring of Student Summaries

To determine whether an automated scoring system can be used to score summaries of the type described in §3, we used a machine learning approach. We test our automated scoring approach for evaluating summaries written by more than 2600 students from the 6th, 7th and 9th grades about two different passages. Specifically, there were a total of 2695 summaries – 1016 written about a passage describing the evolution of permanent housing through history (the passage shown in Figure 1) and 1679 written about a passage describing living conditions on the south pole. The distribution of the grades for the students who wrote the summaries for each passage is shown in Table 1.

In order to evaluate our automated scoring approach, all summaries were also scored by an experienced human rater in accordance with the 5-point holistic rubric described previously. Figure 2 shows the distribution of the human scores for both sets of summaries.

Figure 2: A histogram illustrating the human score distribution of the summaries written for the two passages.

Our approach to automatically scoring these summaries is driven by features based on the rubric. Specifically, we use the following features:
BLEU: BLEU (BiLingual Evaluation Understudy) (Papineni et al., 2002) is an automated metric used extensively in automatically scoring the output of machine translation systems. It is a precision-based metric that computes n-gram overlap (n=1 ... 4) between the summary (treated as a single sentence) against the passage (treated as a single sentence). We chose to use BLEU since it measures how many of the words and phrases and borrowed directly from the passage. Note that some amount of borrowing from the passage is essential for writing a good summary.

ROUGE: ROUGE (Recall-Oriented Understudy for Gisting Evaluation) (Lin and Hovy, 2003) is an automated metric used for scoring summaries produced by automated document summarization systems. It is a recall-based metric that measures the lexical and phrasal overlap between the summary under consideration and a set of “model” (or reference) summaries. We used a single model summary for the two passages by randomly selecting each from the set of student summaries assigned a score of 4 by the human rater.

CopiedSumm: Ratio of the sum of lengths of all 3-word (or longer) sequences that are copied from the passage to the length of the summary.

CopiedPassage: Same as CopiedSumm but with the denominator being the length of the passage.

MaxCopy: Length of the longest word sequence in the summary copied from the passage.

FirstSent: Number of passage sentences that the first sentence of the summary borrows 2-word (or longer) sequences from.

Length: Number of sentences in the summary.

Coherence: Token counts of commonly used discourse connector words in the summary.

ROUGE computes the similarity between the summary S under consideration and a high-scoring summary - a high value of this similarity indicates that S should also receive a high score. CopiedSumm, CopiedPassage, BLEU, and MaxCopy capture verbatim copying from the passage. FirstSent directly captures the “global understanding” concept for the first sentence, i.e., a large value for this feature means that the first sentence captures more of the passage as expected. Length captures the correspondence between the number of paragraphs in the passage and the number of sentences in the summary. Finally, Coherence captures how well the student is able to connect the different “local concepts” present in the passage. Note that:

- Although the rubric states that the students should not be penalized for spelling errors, we did not spell-correct the summaries before scoring them. We plan to do this for our future experiments.
- The students were not explicitly told to refrain from verbatim copying since the summary-writing instructions indicated this implicitly (“... about the whole passage” and “... about one of the paragraphs”). However, for our future experiments, we plan to include explicit instructions regarding verbatim copying.

All the above features are combined in a logistic regression classifier that outputs a prediction on the same 5-point scale as the holistic rubric. We train a separate classifier for each of the two passage types. The 5-fold cross-validation performance of this classifier on our data is shown in Table 2. We also compute the exact agreement as well as adjacent agreement of our predictions against the human scores using the confusion matrices from the two classifiers. The exact agreement shows the rate at which the system and the human rater awarded the same score to a summary. Adjacent agreement shows the rate at which scores given by the system and the human rater were no more than one score point apart (e.g., the system assigned a score of 4 and the human rater assigned a score of 5 or 3). For holistic scorings using 5-point rubrics, typical exact agreement rates are in the same range as our scores (Burstein, 2012; Burstein et al., 2013). Therefore, our system performs quite well on the summary scoring task. For comparison, we also show the exact and adjacent agreement of the most-frequent-score baseline.

1 We use the Weka Toolkit (Hall et al., 2009).
It is important to investigate whether the various features correlated in an expected manner with the score in order to ensure that the summary writing construct is covered accurately. We examined the weights assigned to the various features in the classifier and found that this was indeed the case. As expected, the CopiedSumm, CopiedPassage, BLEU, and MaxCopy features all correlate negatively with score, and ROUGE, FirstSent and Coherence correlate positively.

In addition to overall performance, we also wanted to examine which of the features were most useful to the classifier in predicting summary scores. We ranked the various features using the information-gain metric for both the logistic regression models. The various features are ranked according to the average merit values obtained and shown in Table 3. These rankings show that the features perform consistently for both models.

5 Related Work

There has been previous work on scoring summaries as part of the automated document summarization task (Nenkova and McKeown, 2011). In that task, automated systems produce summaries of multiple documents on the same topic and those machine-generated summaries are then scored by either human raters or by using automated metrics such as ROUGE. In our scenario, however, the summaries are produced by students — not automated systems — and the goal is to develop an automated system to assign grades to these human-generated summaries.

Although work on automatically scoring student essays (Burstein, 2012) and short answers (Leacock and Chodorow, 2003; Mohler et al., 2011) is marginal to the work done here, we believe it is different in significant aspects based on the scoring rubric and on the basis of the underlying RfU framework. We believe that the work most directly related to ours is the Summary Street system (Franzke et al., 2005; Kintsch et al., 2007) which attempts to score summaries written for tasks not based on the RfU framework. The scoring approach uses Latent Semantic Analysis (LSA) rather than a feature-based classification approach.

6 Conclusion & Future Work

We briefly introduced the Reading for Understanding cognitive framework and how it motivated the use of a summary-writing task in a reading comprehension assessment. Our motivation stems from the theoretical suitability of such a task for capturing the ability of a reader to form coherent mental representations of the text being read. We then described a preliminary, feature-driven approach to scoring such summaries and showed that it performed quite well for scoring the summaries about two different passages. Obvious directions for future work include: (a) getting summaries double-scored to be able to compare system-human agreement against human-human agreement (b) examining whether a single model trained on all the data across passages can perform as well as passage-specific models, and (c) using more sophisticated features such as TERp (Snover et al., 2010) which can capture and reward
