Abstract
This study aims to explore pre-service elementary teachers’ understandings of the environment. A survey method was carried out in this study. A close-ended questionnaire and Draw-An-Environment Test (DAET) are administered to pre-service teachers (N=255) after instruction of an Environmental Education course. A rubric (DAET-R) is used for assessing the mental models or images of the environment held by pre-service teachers. Results of this study suggest that the participants’ mental models of the environment are incomplete. Majority of participants’ drawings reflect biotic and abiotic environment. Few drawings include human beings as a part of the environment. The results shows that mean scores do not differ regarding to gender, environmental education background, high school type, parental education level, parental occupation, and monthly family income.

Key words: Mental model, environment, education, pre-service teachers, drawing

Introduction
Though the development in science and technology increases the life standards of people, the development reveals a lot of environmental issues. While humans develop science and technology, they cause emergence of new environmental problems. According to this point of view, peoples’ attitudes and behaviors are origin of environmental issues and this is an educational issue. Loughland, Reid and Petocz (2002) have stated that environmental education is seen to be an important strategy in achieving environmental improvement. The general purpose of environmental education is to provide individuals with the knowledge and skills necessary to protect and improve the environment for all living things (Moseley, Desjean-Perrotta, & Utley, 2010). Teachers must be aware of that factors that shape their environmental understanding to get through the goals indicated by North American Association for Environmental Education “NAAEE” (2004a). The Guidelines for the Initial Preparation and Professional Development of Environmental Educators of the NAAEE, (2004b) states,

The goal of environmental education is to develop a world population that is aware of, and concerned about, the environment and its associated problems, and which has the knowledge, skills, attitudes, motivations, and commitment to work individually and collectively toward solutions of current problems and the prevention of new ones (p. 2).
According to the Guidelines, “educators must possess the understanding, skills and attitudes associated with environmental literacy,” and “environmental literacy hinges on understanding the processes and systems that comprise the environment, including human systems and their influence” (p. 7) (NAAEE 2004b). A large part of our environmental understanding that directs our environmental behavior is derived from sociocultural factors and formal education (Duit, 1991; Payne, 1998).

“Students’ conceptualizations of the environment or their mental models shape the ways in which they understand an environmental issue and guides their environmental behaviors” (Shepardson, Wee, & Harbor, 2007; p328), and this fact is also true for teachers (Moseley et al., 2010). According to these researchers, before teachers can understand environmental issues, firstly they must conceptualize what the environment is, what factors are present in the environment, and how those factors interact to shape and characterize the environment. So, investigating future educators’ knowing and understanding about environmental issues is more important. In order to accomplish the general purpose of the environmental education, individuals both pre- and in-service teachers and students understand the factors that shape their beliefs and perceiving the environment (Moseley et al., 2010).

Theoretical Framework
This research is grounded in mental model theory. Drawings have been used to expose thinking patterns of pre-service elementary teachers in this study. Coll and Treagust (2003) have been defined mental models as representations of reality that people use to understand specific phenomena and make sense of the physical world. Individuals create cognitive or mental models that are based on prior knowledge, existing ideas and past experiences in order to interpret and explain events in the world around them (Moseley et al., 2010). Mental models are incomplete, imprecise and incoherent with the specific domain knowledge (Reinfried, 2006). Although these specific features, Greca and Moreira (2000) states that they are useful, since they are powerful explicative and predictive tools for the interaction of an individual with the world. Reinfried (2006), in her study, asserted that diagnosing the students’ incorrect preconceptions and mental models would be a crucial step of teacher-facilitated mental model building process at all grade levels.

Mental Models
The term “mental model” has been used in many contexts and it plays a significant role in human reasoning. It was formulated, initially, by Kenneth Craik in 1943. Craik proposed that people reason, in general, by carrying out thought experiments on internal models (Nersessian, 1992). Mental models refer to individuals’ internal, mental representations of external, physical phenomena or systems (Gilbert, Boulter, & Elmer, 2000; Vosniadou & Brewer, 1992, 1994). The major feature of this mental representation is its analogous structure to what is represented. That is, a mental model can be thought of as an imaginary structure that corresponds to the externally represented or perceived system in terms of the spatial arrangement of elements involved in the system and the relationships between or among these elements (Chiou & Anderson, 2010). Mental models influence cognitive functioning and can provide science education researchers and teachers with valuable information about the learners’ conceptual framework, that is, their underlying knowledge structures (Vosniadou, 1994). Mental models may serve a number of purposes and function to provide explanations and justifications and to serve as mnemonic devices for memory enhancement (Coll & Treagust, 2003). An important, often overlooked, function that
mental models serve is to predict behavior (Williams, Hollan & Stevens, 1983). Mental models can also be divided into physical and conceptual mental models, where physical models represent the physical world; conceptual models represent more abstract matters (Johnson-Laird, 1983). Physical mental models are mental constructs of physical entities—real or imagined, whereas conceptual mental models are mental constructs of concepts, models, or abstractions (Coll & Treagust, 2003).

Drawings

Researchers have used drawings to examine thoughts and attitudes about various content areas for years. These studies usually involve elementary students, rather than the teachers themselves (Burton, 2012). The reason that drawing studies is done with elementary level students may be easier to summarize their ideas with drawings than to receive answers or to obtain verbal or written data during these ages.

Peoples have cognitive or mental models in the base of their prior knowledge, experience and related ideas and they serve the mental and/or cognitive models for the aim of explaining things in their life. Strauss (2001) suggested that mental models are the appropriate psychological entity to be addressed in the study of teacher cognition. Strauss asserted that an implicit mental model organizes thinking and teaching behaviors. Similarly, Haim, Strauss and Ravid (2004) explored how teachers’ mental models related to their subject-matter knowledge. Contrary to traditional claims of the importance of subject-matter knowledge in their instructional behaviors, they found teachers’ mental models, rather than teachers’ depth of content knowledge, drove their instructional practices. Therefore, investigating and summarizing mental and/or cognitive models of pre-service and/or in-service teachers related to environment is important.

A lot of research studies have been done related to students’ mental models in “physics education” (e.g. Borges & Gilbert, 1999; Hubber, 2006; Jabot, & Henry, 2007), “chemistry education” (e.g. Adbo & Taber, 2009; Chittleborough, 2004; Coll & Treagust, 2003a, b; Lin & Chiu, 2010; McClary & Talanquer, 2011), “biology education” (e.g. Chang, 2007; d’Apollonia, Charles & Boyd, 2004; Patrick, 2006), “environmental education” (e.g. Reinfried, 2006; Shepardson, Choi, Niyogi, & Charusombat, 2011; Shepardson, Wee, Priddy & Harbor, 2007), “earth sciences education” (e.g. Gobert, 2000; Panagiotaki, Nobes, & Potton 2009), “astronomy education” (e.g. Cin, 2013; Samarapungavan, Vosniadou & Brewer, 1996; Vosniadou & Brewer, 1994).

Drawing images before writing or verbalizing ideas can foster more creative responses and help generate ideas, because often language can slow down the creative process (Caldwell, & Moore, 1991). In addition, it has been stated that exploration of ideas through drawing does not require the cognitive demands often found when using language. Therefore, drawings are usable with adults, as well as children, to explore both conscious and unconscious thoughts, experiences, and emotions. Several researches have also been done related to pre- and in-service teachers’ mental models about “science teaching” (Minogue, 2010; Tatar, Yildiz Feyzioglu, Buldur, & Akpinar, 2012; Subramaniam, 2013; Ucar, 2012; Wilke & Losh, 2012), “specific scientific issues” (Chiou & Anderson, 2010; Heywood, Parker & Rowlands, 2013) “technology” (Krauskopf, Zahn & Hesse, 2012; Zhang & Xu, 2011), “ideal teacher” (Mensah, 2011), “environment” (Desjean-Perrotta, Moseley, & Cantu, 2008; Moseley et al., 2010), and “classroom structure” (Matteson, Ganesh, Coward, & Patrick, 2012).

Environmental education research studies have frequently examined the relationships between environmental knowledge, attitudes, behaviors, and literacy. Examples for these studies are Boeve-de Pauw and Van Petegem, (2011), Carrier (2007), Digby...
(2010), Evans (2007), Prabawa-Sear and Baudains (2011), Robelia and Murphy (2012), Tal (2010), and Teksoz, Sahin and Tekkaya-Oztekin (2012). There are a few studies about individuals' mental models of the environment (Moseley et al., 2010).

Pre-service teachers will play a critical role as they will be responsible for the education of a significant proportion of the young people in the future. Teachers have also key role for effective environmental education in the classroom and teachers can influence pupils' worldviews and attitudes, their interactions with the environment, participation in decision-making and ability to make informed responsible choices (McKeown and Hopkins 2002). If teachers (or pre-service teachers as teachers of the future) lack knowledge, skills or commitment, it is unlikely that they will succeed as leaders of environmental change in schools and produce environmentally literate students (Wilke 1985; NAAEE 2004). For this reason, in this research, we aimed to investigate pre-service elementary teachers' mental models of the environment.

Research Questions

Two research questions guided this study in pre-service elementary teachers' mental models of the environment. First, “what are pre-service elementary teachers' mental models of the environment?” Moseley and her colleagues (2010) suggested an investigation whether learners' mental models differ according to their age, gender, socioeconomic status (SES) and cultural structure in their report for future researches. Therefore, the second research question is, “Are there a significance between pre-service elementary teachers' drawing scores by their socioeconomic status, gender, parental education level and parental occupation, family income?”

Methodology

Participants and Course Context

Participants in this study were 255 second-year students (n=255; male, n=75; female, n=180) from a state university of Education Faculty, elementary level teacher program. The aim of this program is to prepare elementary teachers for grades 1-4. Two instructors teach the Environmental Education course in third semester of the program in six classes. The Environmental Education course is offered to students after accomplishment other specific science courses (e.g. biology, chemistry). The compulsory course content includes the some issues such as basic concepts and principles of ecology, ecosystems, food chain, food web, habitat, competition, symbiosis, mutual life, survival of life, soil biomes, energy flow, circulation of matter, increasing of population, ecological impact, erosion, deforestation, urban environment, behavioral pollution, environmental pollution, marsh and waste waters, environment-related decision-making, soil and water resources and their management, environmental sensitivity, environmental institutions and organizations in Turkey and in the World.

Research Instruments

To answer the research questions, a survey method was used by an instrument consisting of fixed-response and open-ended sections. The former includes questions to compile participants' demographic characteristics (gender, age, mother's education, father's education, mother's occupation, and father's occupation). The latter section of the instrument (Draw-An-Environment Test, DAET) was asked participants to draw and
define the environment. DAET was adapted by Desjean-Perrotta, Moseley and Cantu (2008) from an instrument was developed by Shepards on (2005). The first part of the DAET has the prompt 'My drawing of the environment is...' with room on the page for a drawing. The second part of the instrument contains the prompt to complete the sentence 'My definition of the environment is...' (Appendix A). Open-ended responses have limitations: They may be short, lack depth, and possibly be difficult to code if the writing is illegible or the grammar or sentence construction is difficult to understand.

Draw-An-Environment-Test Rubric (DAET-R) was used for assessing the participants’ drawings. It was developed, by Moseley et al. (2008), using the definition of the environment in NAAAE (2004b) as a filter. There are four factors: humans, other living organisms (biotic), physical environment (abiotic) and built and designed environment - were used as rubric categories for scoring the drawings. The DAET-R is divided into four sections that focus on degree of evidence in the drawings of interactions of the four environmental factors with each other: a) factor not present, b) factor present, c) factor interacting with other factors, and d) two or more factors interacting within a system approach (Moseley et al., 2010). Based on the rubric, it could be assigned degrees of evidence of these factors using a score of 0-3. For example, assessing of drawings regarding to abiotic factor is given in Table 1.

Table 1.

Scores for abiotic factor of rubric from Moseley et al. (2010)

<table>
<thead>
<tr>
<th>Factor</th>
<th>Non Present</th>
<th>Present</th>
<th>Interactions with other factors</th>
<th>System interactions made explicit</th>
</tr>
</thead>
<tbody>
<tr>
<td>Abiotic</td>
<td>Abiotic items (mountains, rivers, Sun, or clouds) drawn without any apparent interaction with other factors.</td>
<td>Abiotic items drawn interacting with other abiotic items and/or another factor (e.g., wind blowing a palm tree), but without special emphasis placed on the influence of the interaction on the environment.</td>
<td>Abiotic items drawn with obvious deliberate emphasis placed on interaction with one or more factors and the influence of that interaction on the environment through the use of special indicators such as conceptual labels and/or arrows.</td>
<td>Total Score: (…..) from this factor</td>
</tr>
</tbody>
</table>

0 Point 1 Point 2 Point 3 Point

For each factor, if the factor is merely present in a drawing, a score of 1 is given. If any particular factor is seen as interacting with one or more factors, a score of 2 is given. If the participant tried to indicate an interaction among factors with an emphasis on a system approach to the definition of environment, a score of 3 is given. A score of zero is given if there was no evidence of a factor in the drawing. For any drawing, a participant can take a total score from 0 to 12. The higher the score, the more evidence there is of the participant’s understanding of the environment’s interactions between the four factors (Moseley et al., 2010).
Exploring Pre-Service Elementary Teachers' Mental Models of the Environment

The Collection of Data

Data were collected during an Environmental Education course hour in last week of December 2012 (at the end of the semester). Instructors, in six sections of the course for participants, administered the DAET using a common set of directions as printed on the survey. Pre-service teachers first drew a picture of the environment and then wrote their definition of the environment by completing an open-ended sentence. Their drawings were intended to provide not only a complementary source of how they represented their mental models in addition to their verbal reports but also a means of gaining rich information about their inner analogue representations of the environment. No time limit was given to complete the survey, but most of the surveys were completed in an average of 20 minutes. The pre-service teachers' surveys were collected and coded to assure anonymity.

Data Analysis

A descriptive analysis method was used to evaluate data. Initially, the background characteristics of the participants had been recorded and documented in frequencies and percentages. Then, participants' drawings evaluated according to the DAET-R and individual scores were compared and consensus was achieved among the scorers for each drawing. Lastly, data were used to determine frequency of factors and interactions of those factors. Statistical significance was determined using $\alpha= .05$ alpha level. Independent samples t-test and one-way ANOVA were used in data analysis.

Validity and Reliability of the Instrument DAET-R

In order to assess the reliability and validity of the DAET-R, both percent agreement measure and Pearson's product-moment correlation were used to determine the degree of consistency among scorers (Moseley et al., 2010). Analyses have been repeated for re-evaluation of the validation and reliability of the DAET-R. For this study, percent-agreement among the three scorers ranged from 62% to 83% on each factor. Correlation coefficients of inter-rater reliabilities among three scorers were summarized in Table 2.

Table 2.

Pearson’s product-moment correlation coefficients (n=255).

Results

Demographic Characteristics

The participants included 255 second-year pre-service teachers. The gender profile of the participants indicates that more than two-thirds are female. Gender data revealed that more women than men took place in the elementary teacher education program. This is in line with Saban's (2003) findings in a Turkish context and with a cultural belief that teaching profession is more appropriate for women than for men (Hatch, 1999). The socioeconomic background of the participants reveals that more than half of the mothers as well as one-thirds of fathers have primary level of education or less, and that the majority of the participants have one-parent working families (See Table 3).

**Humans:** Table 4 suggests that some pre-service elementary teachers do not consider humans to be an integral component of the environmental system. A quarter part of the participants’ drawings didn’t contain any human image (Fig. 1). Forty-four percent of them drew humans with no obvious interaction with other factors in the environment. Thirty-one percent of the participants drew humans interacting with other factors. Only 5% actually indicated any kind of system approach in their drawings of human.

![Figure 1. A drawing example does not contain the human](image)

**Living Things:** In Table 4, eight percent of pre-service elementary teachers don’t consider living things (cat, dog, fish, cow, tree, flower, etc.) to be component of the environmental system (Fig. 2). Seventy-one percent of the participants drew living
things with no obvious interaction with other factors in the environment. Twenty-one percent of the participants drew living things interacting with other factors. Only two percent of them actually indicated any kind of system approach in their drawings of living things.

Figure 2. A drawing example does not contain living things

Abiotic; According to Table 4, ten percent of participants do not consider abiotic components (e.g. mountain, sun, cloud, river, etc.) as a part of the environmental system (Fig. 3). Seventy-one percent of the participants drew abiotic components with no obvious interaction with other factors in the environment. Seventeen percent of the participants drew abiotic interacting with other factors. Only two percent of them actually indicated any kind of system approach in their drawings of abiotic (non-living).

Figure 3. A drawing example does not contain the abiotic components
Human Built or Designed Objects; According to Table 4, eighteen percent of the pre-service elementary teachers don’t consider human built or designed objects (e.g. factory, car, building, etc.) as a component of environmental system. Thirty-two percent of the participants drew objects with no obvious interaction with other factors in the environment (Fig. 4). Forty-nine percent of the participants drew human built or designed objects interacting with other factors. Only four percent of them actually indicated any kind of system approach in their drawings of human built or designed objects.

Figure 4. A drawing example does not contain built or designed objects

Participants’ total scores of drawings were divided into three broad categories; Model 1: one or more factors present, Model 2: one or two factors interacting with another factor, and Model 3: two or three factors interacting within a system approach (Table 5). These categories were defined for the participants’ mind models. Model 1 has one or more factors, 43.5% of participants have this model. Model 2 has one or two factors interacting with another factor and 52.5% of participants have this model. Model 3 has two or three factors interacting within a system approach. Only 4.0% of participants have this model.

Forty-four percent of the drawings scored a four or less points, indicating factors the lack of one or more factors in the drawings. Only four percent of the drawings scored 9-12 points, indicating factors depicting interactions within a system approach. That is, ten participants at least in one factor, presented interaction with system approach. In fact, there is no any drawing scored 12 points.

**Total Scores and Socioeconomic Characteristics**

The mean scores of males and females are compared with independent samples t-test (Table 6). Results show that mean scores do not differ between males (M=4.93, SD=2.00) and females (M=4.61, SD=2.11) at the .05 level of significance (t=1.149, p=.252). Although there is not a significant differences between means, on average score of females is higher than the score of males.

*p > .05*
Analyses were completed using one-way ANOVA with the mean scores of participants by graduated high school, parental education levels, occupations and their family income. Analysis of mean scores did not reveal significance by high school type \( F(2.252)=0.164, p=.849 \), by the fathers' \( F(3.251)=0.970, p=.407 \) and mothers' \( F(4,249)=1.917, p=.108 \) education levels. Analysis of mean scores did not reveal significance by their mothers' occupations \( F(5.248)=0.788, p=.559 \), but did reflect a significant effect of their father's occupations \( F(5.249)=2.531, p=.029 \). Post hoc comparisons using Tukey HSD test indicated that the mean score of the participants whom father's occupation is artisan \( (M=5.42, SD=2.17) \) was significantly different from than the mean score of the participants whom father is retired \( (M=4.29, SD=2.12) \). There was not a significant effect of family income \( F(2.252)=2.217, p=.112 \) on mean scores of participants.

**Discussion**

The aim of this study is to examine pre-service teachers' perceptions about the environment and whether the mean scores differ regarding to several variables or not. For this purpose, drawings of the environment and demographic characteristics of pre-service teachers have been collected. Moseley and her colleagues (2010) also offered an investigation about how learners' mental models affected by age, gender, socioeconomic status (SES) and cultural structure in their research for future researches. The relationships among some of these variables were investigated in this study and the obtained results were reported. Even though the mean score of pre-service teachers does not differ significantly by gender, mean score of females was higher than of males. For this reason, we can say that the females are more responsive for environmental issues rather than males. It has been found that the girls were more sensitive to environment than boys (Taylor et. al., 2007), some studies have reported gender differences, with males scoring higher in environmental knowledge (Coyle, 2004; Kollmuss & Agyerman, 2002; Tikka et al., 2000).
Another result is average scores of participants do not differ by their family income, and educational levels of their parents. Although there is no significant effect of environmental education background on average score, participants with environmental education background have higher scores than who have not.

Another result of this study is majority of pre-service teachers perceive the environment as abiotic and living things. It is an impressive result that few participants’ drawings included humans as a part of environment. In the literature, it has been put forwarded that students perceive environments as living area (Burgess, & Mayer-Smith, 2011; Köşker, 2013; Wilhelm, & Schneider, 2005). Furthermore, the results of this research get along with the literature. In this study, when the pre-service teachers’ drawings were investigated, it has been seen that the majority of drawings included polluting elements and facts (factory, motor vehicles, etc.). Thus, it can be said that most of them have awareness about environmental pollution and polluting factors. Environmental issues which known as the vast majority derived from human-induced factors are not only problem of a country but also the entire world’s problem. Melting of glaciers, the increasing number of extinctions and climate change that we couldn’t
explain the meaning threats both our planet and living things. Because the best part of the cause of environmental problems are arisen by the humans, we need to think about the reasoning requirement whether all individuals, including especially teacher candidates have this environmental consciousness or not. Otherwise, future generations will not be as lucky as we about the environment.

Teaching actual cause of environmental problems to the individuals is very important for a sustainable environment. Creating this awareness and giving this responsibility for future generations depends on consciousness about sustainable environment of teachers as architects of the future. This situation reveals that the importance of environmental education in education faculties. Environmentally knowledge and skills of future teachers will be herald for a healthy environment.
