INTRODUCTION

Scientific literacy is widely accepted as an important educational and societal goal (NAS, 2007). There are different approaches for the conceptualization of scientific literacy. Roberts (2007) categorized the approaches about scientific literacy along a continuum between two overarching visions, Vision I and Vision II. In Vision I, scientific literacy refers to having a robust understanding of scientific findings, whereas in Vision II, scientific literacy emphasizes the understanding and use of science beyond the traditional boundaries of science in a broader scope. This involves decision-making in real-life situations related to science and is influenced by other disciplines such as politics, economics, and ethics (Sadler and Zeidler, 2009). In this view, scientific literacy mainly aims to raise socially responsible and competent citizens (Kolstø, 2001). Programme for International Student Assessment (PISA) initiatives aiming to contribute to the quality and equity of learning outcomes for children, young people, and adults also encourage Vision II’s scientific literacy (OECD, 2007; Sadler and Zeidler, 2009). According to PISA’s definition of scientific literacy, scientifically literate individuals are expected to be “willing to engage with science-related issues, and with the ideas of science, as a reflective citizen” (OECD, 2007. p. 35).

Undergraduate teaching has an important impact on the nation’s future (Kober, 2015). Making decisions on complex issues such as new viruses, global climate change, or challenging issues of daily life requires both knowledgeable scientists and engineers and a scientifically literate public (Kober, 2015). According to the National Research Council (NRC, 2011), undergraduate science, technology, engineering, and mathematics (STEM) students need to develop skills to make informed decisions. Therefore, it can be argued that to develop scientifically literate public, STEM-related programs should also consider new ways of teaching and learning in a way that enculturating people to think, to act, to do, and to participate in certain ways (Kober, 2015). It has been argued that currently, STEM-related programs disregard “sociologics” of scientific decisions by emphasizing science and its processes (Zeidler, 2014). These programs consider scientific literacy in the definition of Vision I’s scientific literacy. However, it is not unreasonable to assume that a scientifically literate person will have the responsibility to make decisions about policy, research, community, or family (Zeidler, 2014). In such a case, although individuals have the necessary knowledge and technical competence, they would not be inclined to enact that knowledge due to the need for being engaged in subsequent decisions about the physical or social environment. Therefore, while scientific literacy is a prerequisite for making responsible
decisions, awareness of moral issues is required for scientific literacy (Zeidler, 2014). Developing science-based decision-making skills in controversial contexts including moral issues are a challenge for educators in STEM-related fields (Manske, 2013). Therefore, STEM-related programs of universities need to include ethical and social concerns into their education (Hall et al., 2017).

Socio-scientific issues (SSI) provide a fruitful context for including moral and ethical issues in science teaching and learning because socio-scientific decision-making requires scientific knowledge acquisition, nature of science (NOS) understanding, as well as an awareness of moral and ethical issues (Sadler, 2004). SSI are the dilemmas in which both society and science play an important role (Sadler, 2004). Technological developments, such as constructing a nuclear power-plant, gene cloning, and tissue transplant, are examples of SSI that affect society. SSI are open-ended problems that do not have clear-cut solutions. There can be multiple plausible solutions to SSI that are not necessarily determined by scientific considerations (Sadler, 2011). These issues are also influenced by different societal factors, including politics, economics, and ethics (Barab et al., 2007; Sadler, 2011).

SSI can serve as a vehicle for addressing citizenship education (Kolstø, 2001; Zeidler et al., 2005). To specify how this can be accomplished, Sadler et al. (2007) introduced the theoretical construct of socio-scientific reasoning (SSR). According to the researchers, decision-making in the SSI context requires the inclusion of the following four practices:

1. Recognizing the inherent complexity of SSI
2. Examining issues from multiple perspectives
3. Appreciating that SSI are subject to an ongoing inquiry

First, citizens with SSR competencies should recognize the complexity of SSI. Therefore, practices aiming to develop SSR should avoid sifting a single factor out from the broader context. Instead of restraining the analysis of SSI to a simple cause-effect reasoning, multiple, dynamic interactions of factors within SSI should be recognized (Sadler et al., 2007).

Moreover, SSI reasoning practices require acknowledging the existence of multiple perspectives. Citizens with SSR competencies should recognize the perspectives other than their own standpoint and critically evaluate arguments of each perspective. Argumentation has been considered as one of the most appropriate pedagogies to gain these competencies, as argumentation provides productive pedagogy and assessment schemes for considering counter-arguments from multiple perspectives and providing rebuttals for these counter-arguments (Erduran et al., 2004).

SSI are ill-structured problems; therefore, they are open to social and scientific inquiry (Sadler et al., 2007). Therefore, any citizen with SSR competencies should be in search of specific information about the issue. Congruent with the required thinking style in inquiry, citizens should also be skeptical about the sources of information in SSI reasoning. Since there are multiple perspectives in SSI, citizens should be aware of the potential biases caused by the distortion of data from a particular perspective. They should not accept any information without analyzing it for possible bias.

The graduates of STEM-related departments are candidates to be citizens who have active roles in the decision-making of such controversial issues. Therefore, it is crucial for them to have SSR competencies to enact their knowledge in making decisions on policy, research, community, family, and so on, as responsible citizens.

**SSR and NOS**

Before explicating the role of the conceptions about the NOS on SSR, it would be better to explain what is meant by NOS. There is not a consensus for the meaning of NOS among philosophers, historians, or science educators. Among science educators, there are seven commonly used characteristics of NOS (Lederman et al., 2002; Lederman et al., 2014). According to this general definition of NOS, scientific knowledge is tentative, empirically-based, subjective, involves human inference, imagination, and creativity, and is socially and culturally embedded. The other two additional aspects are related to the difference between observation and inference, and between scientific theories and laws.

In the past decade, alternative perspectives about NOS have been proposed. The idea of “Whole Science” (Allchin, 2011), “Features of Science” (Matthews, 2012), “Family Resemblance Approach (FRA)” (Irzik and Nola, 2014), and “Reconceptualized Family Resemblance Approach to Nature of Science (RFN)” (Erduran and Dagher, 2014) are examples of these perspectives.

According to Irzik and Nola (2014), FRA has significant advantages over previous approaches to NOS. They conceptualize science as a whole under two themes: Cognitive epistemic system and social-institutional system. Rather than discrete ideas about NOS tenets, FRA proposes a broader, inclusive, and united framework compiled under eight categories. Four of these categories are about science as a cognitive epistemic system, which are scientific activities/processes, aims and values, scientific methodology and methodological rules, and scientific knowledge; while four categories are about science as a social system, which are professional activities, scientific ethos, social certification and dissemination of scientific knowledge, and social values. The unique contribution of this approach is the emphasis on the differences among scientific disciplines (e.g., relative role of experimentation on astronomy and medicine) as well as the similarities and overlapping characteristics (e.g., naturalism) of different disciplines. Moreover, with the new way of the reconceptualization of the social embeddedness of science, the influence of noncognitive factors (social, cultural, historical, political, and economic factors) on science is highlighted in this approach. Furthermore, contrary to a frozen picture of
NOS presented by the consensus view of NOS, FRA lays emphasis on the dynamic and open-ended NOS by recognizing the emerging changes in the characteristics of science (Irzik and Nola, 2014). Finally, FRA is more comprehensive than the consensus view of NOS, making it flexible for including content according to different philosophical orientations (Irzik and Nola, 2014).

Erduran and Dagher (2014) reconfigured Irzik and Nola’s (2014) FRA to make it applicable to science education research. Since Erduran and Dagher (2014) criticized Irzik and Nola’s (2014) FRA as being limited in social-institutional aspects, they decided to add an outermost circle to the FRA model. They added three more components to FRA in this reworked framework: Social organizations and interactions, political power structures, and financial systems. Then, they defined 11 categories of Reconceptualized FRA-NOS (RFN). Their visual tool of RFN wheel with the newly added third circle provides a valuable tool for science education researchers to conceptualize RFN.

To date, researchers have argued that an individual’s NOS conception influences the way of thinking on SSI (Kolsto, 2001; Sadler, 2004; Sadler et al., 2004; Zeidler et al., 2002). For example, Zeidler et al. (2002) investigated the relationship between students’ NOS conceptions and decision-making on SSI. Although they found few clear instances indicating a discernible relationship, they emphasized the link between NOS and social enterprise of science in students’ conceptualizations. Sadler (2004) further investigated high school students’ NOS conceptions and their response to conflicting evidence in socioscientific context and found that the negotiation of conflicting evidence regarding SSI was influenced by NOS conceptions. Similarly, Sadler (2004) also found that students’ beliefs about social embeddedness of scientific knowledge influenced their decision-making in SSI.

On the other hand, there are also findings indicating no relationship between NOS understanding and reasoning on SSI (Bell and Lederman, 2003; Walker and Zeidler, 2003). In Bell and Lederman’s (2003) study, the participants were a group of college professors and a group of research scientists. The participants’ NOS understanding was found not to be related to their decision-making in SSI. However, the researchers concluded that this result would not necessarily be the case with students; therefore, the results cannot be generalized to the public as a whole.

In a more recent study, Khishfe (2012) found no significant change in participants’ decisions as a result of NOS instruction. However, the researcher found that more participants related their discussions to the empirical, tentative, and subjective NOS when making decisions about SSI. Similarly, Khishfe et al. (2017) also investigated students’ understanding of NOS and their arguments in SSI context. Although they could not find significant correlations between argument components and NOS aspects, their qualitative results revealed that students who generated well-developed arguments also possessed informed understandings of NOS aspects.

Together, these studies highlight the need for considering the relationship between NOS conceptualization and reasoning about SSI topics. Although there are contradictory results about the relationship between them, the majority of qualitative studies indicated that students’ decision-making or reasoning on SSI are closely related to their conceptions of NOS. Studies mostly focus on the relationship between conceptions about subjective and social-embeddedness of NOS and the reasoning on SSI. Therefore, in this study, Erduran and Dagher’s (2014) RFN was decided to be used with the aim of providing a richer focus on social embeddedness of science.

**Rationale of the Study**

Studies have indicated the role of SSI in raising scientifically literate citizens. Undergraduate programs, especially STEM-related programs, should consider new ways to develop students’ competencies to help them become informed citizens. This can be achieved by developing SSR competencies and NOS conceptions. To find ways for developing SSR competencies and NOS conceptions, students’ existing competencies and conceptions should be determined. Therefore, the following research question was investigated.

- What are the undergraduate students’ SSR competencies and NOS conceptions?

There are varieties of undergraduate programs in universities resulting in a wide variation in the curriculum. To provide an insight for the researchers who want to develop SSR competencies and NOS conceptions of their students, differences among SSR competencies and NOS conceptions of students from different faculties were decided to be investigated in this study. Understanding whether there are differences in different faculties and where these differences lie can give us some clues about the ways of developing SSR competencies and NOS conceptions in different faculties. For this purpose, the following research question was investigated.

- What is the difference, if any, among students from five different faculties (dentistry, science, engineering, health sciences, and technology) in terms of their SSR competencies and NOS conceptions?

Previous research has documented conflicting results about the relationship between NOS conceptions and decision-making about SSI topics. It is argued that a citizen who understands the characteristics of science and scientific knowledge can easily evaluate the evidence and be aware of multiple perspectives about the same perspective (Khishfe, 2012). This implies that students’ reasoning and decision-making on an SSI is closely related to their NOS conceptions. However, qualitative results indicated a close relationship, there are no clear quantitative results indicating a relationship between SSR and NOS conceptions. Therefore, in this study, the relationship among undergraduate students’ SSR competencies (complexity, perspective taking, inquiry, and skepticism) and NOS conceptions (aims and values, scientific practices, methods and methodological rules, scientific knowledge, and socio-institutional systems) were decided to be investigated. For this purpose, the following research question was investigated.
• What is the relationship between SSR competencies (complexity, perspective taking, inquiry, and skepticism) and NOS conceptions (aims and values, scientific practices, methods and methodological rules, scientific knowledge, and socio-institutional systems) of undergraduate students?

METHODS
Research Design and Sample
The survey research methodology was utilized in this study to gather data about undergraduate students’ SSR competencies and conceptions of NOS. The participants for this study included a convenience sample of 169 students (18–32 years old), who were from different departments of different faculties in a public university located in Ankara, Turkey. There are nine faculties in this university, dentistry, pharmacology, science, education, architecture, engineering, health sciences, sports sciences, technology, medicine, and applied sciences. To reach undergraduate students from different faculties, data were collected in elective courses offered to students of all faculties. Undergraduate students who were enrolled in these elective courses, from dentistry, science, engineering, health sciences, and technology faculties, were involved in this study conveniently.

All of the participants stated that they had not taken a course in which SSI were discussed. Therefore, they did not have any experience of reasoning on SSI. The demographics of the participants are given in Table 1.

Data Collection
The Quantitative Assessment of SSR (QuASSR) (Romine et al., 2017) and the NOS questionnaire (Kaya et al., 2017) were used for data collection. The survey instruments were administered to the undergraduate students in their classrooms by the author of this study. The approximate time of filling the instruments was 40 min in total. Before administration, the researcher informed the participants about how to fill out the questionnaire. An informed consent form was distributed to each participant before the administration of the instruments. Participants voluntarily agreed to participate in the study. Only after they signed that the informed consent form was they administered the survey instruments.

QuASSR
QuASSR includes two SSI scenarios, each of which has implications for ecology, economics, and the rights of different groups. There are 11 questions in two-tiered ordered multiple-choice format in each scenario. In the first tier, respondents answer a yes/no question. In the second tier, respondents select the best choice that represents the reason for their choice in the first tier. The answers to the second tier questions are composed of three main patterns of reasoning which are assessed on a three-level ordinal scale (0 = low SSR, 1 = moderate SSR, and 2 = high SSR). Different questions aim to assess different dimensions of SSR. There are two items for complexity, two items for perspective-taking, three items for inquiry, and three items for skepticism dimensions. One item only asks for their position on the issue, but it is not rated. The Cronbach’s alpha reliability value for the test with the combination of two scenarios was reported as 0.79.

The instrument was translated into Turkish. For translation and adaptation, a back-to-back translation was done. An expert committee including three science education researchers, one of which is specifically an expert in SSI, and one language expert provided their comments on the translated instrument. The translated instrument was administered to an undergraduate student for face validity.

The test was piloted with 73 undergraduate students. Cronbach’s alpha reliability value was found to be 0.78 in the pilot study. The reliability value of the test in the current study was 0.82.

NOS questionnaire
To assess undergraduate students’ conceptions of NOS, Kaya et al.’s (2017), “Nature of Science Questionnaire” was used. The questionnaire includes five sub-dimensions of RFN. There are nine items in “Aims and Values of Science (AV),” 15 items in “Scientific Practices (SP),” 12 items in “Scientific Knowledge (SK),” 12 items in “Scientific Methods and Methodological Rules (M),” and 20 items in “Social-Institutional Systems of Science (SI)” sub-dimensions. There are a total of 70 items using a 5-point Likert scale format ranging from strongly disagree to strongly agree. The Cronbach’s alpha reliability value of the questionnaire was reported to be 0.77.

The test was piloted with 73 undergraduate students. The Cronbach’s alpha reliability value was 0.80. The reliability value of the test in the current study was 0.87.

Data Analysis
To answer the first research question, descriptive analysis was performed to figure out undergraduate students’ SSR competencies and NOS conceptions. For the second research question, to figure out the differences among undergraduate

students’ SSR and NOS scores, a one-way between-group multivariate analysis of variance (MANOVA) was performed. Finally, for the third research question, to investigate the relationships among the dimensions of SSR and NOS, a Pearson product-moment correlation coefficients were calculated.

RESULTS

Descriptive Analysis

Undergraduate students’ SSR competencies were explored based on their scores on the QuASSR scale. Participants’ mean value was 1.001 out of 2, indicating moderate SSR (Table 2). Participants’ SSR competencies were below the moderate level in the dimensions of SSR, except for perspective-taking dimension. Participants had the highest score (M = 1.267) for the perspective-taking dimension. This dimension aims to measure participants’ competencies in examining issues from multiple perspectives. On the other hand, they obtained their lowest score for the skepticism dimension. This dimension aims to determine participants’ competencies of examining potentially biased information with skepticism.

Moreover, as mentioned, the QuASSR is composed of questions related to two scenarios: Fracking in Pavilion Wyoming and Branville Bay. As the descriptive results revealed, there was not a clear difference between the scores of different scenarios as well as the total score. Similarly, Romine et al. (2017) did not find a variation between the two scenarios. They suggested the consideration of different dimensions as a single construct. Therefore, while investigating differences among faculties, the total SSR scores will be used assuming that each scenario and methodological rules dimensions (M = 3.282) was relatively lower.

Undergraduate students’ NOS conceptions were measured using Kaya et al.’s (2017) NOS questionnaire, which includes five different categories of reconceptualized FRA. Participants’ score on the whole test indicated that (M = 3.60) their NOS understanding were moderate (Table 3). Their scores on different dimensions were close to each other. While participants’ score on socio-institutional systems dimension (M = 3.746) was relatively higher than the other dimensions, their score on methods and methodological rules dimensions (M = 3.282) was relatively lower.

SSR: Socio-scientific reasoning, SD: Standard deviation

Differences in SSR and NOS

To answer the second research question, a one-way between-group MANOVA was conducted with two dependent variables (SSR and NOS) and one independent variable (faculty type). Preliminary assumption testing was conducted to check normality, linearity, univariate and multivariate outliers, homogeneity of variance-covariance matrices, and multicollinearity. The results revealed that there was a statistically significant mean difference among the participants from different faculties on the combined dependent variables (F (3, 156) = 4.823, p = 0.000; Wilks’ Lambda = 0.785; η² = 0.114), indicating medium effect size. When the results of the dependent variables were considered separately, both SSR (F (4, 156) = 6.923, p = 0.025; η² = 0.155, large effect size) and NOS (F (4, 156) = 2.872, p = 0.000; η² = 0.071, medium effect size) reached a statistical significance, using a Bonferroni adjusted alpha level of 0.025 (Table 4).

To better understand the differences among faculties in terms of each dependent variable, post hoc analysis was performed using Tukey honestly significant difference test (Table 5). Regarding SSR, the lowest mean scores of SSR were found for the science students (M = 0.72, standard deviation [SD] = 0.19) and it is significantly lower than the engineering (M = 1.01, SD = 0.29) and health science (M = 1.15, SD = 0.29) students’ scores. Moreover, the health science students’ scores were significantly higher than the technology students’ scores (M = 0.95, SD = 0.30). The mean scores of the dentistry students were not statistically different from other students’ scores.

Similarly, the lowest mean scores of NOS were found for the science students (M = 3.27, SD = 0.35). It was significantly lower than the dentistry (M = 3.58, SD = 0.24), engineering (M = 3.55, SD = 0.38), and health sciences (M = 3.53, SD = 0.31) students.

Relationship between SSR and NOS

*p<0.025
of NOS (Table 6). The data pertaining to the dimensions of SSR and NOS were obtained by taking the mean of the related items in the QuASSR and NOS questionnaire, respectively. Preliminary analyses were performed to ensure no violation of the assumptions of normality, linearity, and homoscedasticity.

When the relationship between the NOS scores and the SSR scores obtained from the whole scale was examined, it was seen that there was no significant relationship. All of the relationships among NOS components were significant, with varying degrees of strength. Similarly, there were significant relationships among SSR components. However, the relationships among the components of NOS and components of SSR were not significant, except the weak relationship between perspective-taking dimension of SSR and scientific practices dimension of NOS ($r = 0.164$, $p < 0.05$).

**DISCUSSION**

In this study, undergraduate students’ SSR competencies and NOS conceptions were investigated. Participants’ average score over the whole scale of SSR revealed a moderate SSR competency. However, their competencies on the dimensions revealed a weak correlation between perspective-taking dimension of SSR and scientific practices dimension of NOS ($r = 0.164$, $p < 0.05$).

Together with the results of other previous qualitative and quantitative studies, the results of this study indicated that skepticism and inquiry are the dimensions of SSR participants struggle with the most. To tackle the historical “siloed” approach to STEM, students enrolling STEM-related undergraduate departments need to be engaged in effective resolution of SSI (Zeidler, 2014). This requires individuals to consider the complexity of the SSI across multiple perspectives, recognize the need for ongoing inquiry as well as to approach the available data with skepticism. As science educators, our goal should be helping students to become critical evaluators of science content (Witzig et al., 2013). Therefore, the awareness of undergraduate students in different faculties should be increased about the possible bias in data in such issues. Media

Means with the same letters (a,b,c,d) are not significantly different from each other; means with different letters (a,b,c,d) are significantly different from each other. *$p<0.05$ (two-tailed). SD: Standard deviation, SSR: Socio-scientific reasoning, NOS: Nature of science
literacy can be a key strategy to read scientific data skeptically (Cooper, 2011). For this reason, in addition to the courses related to their professions, faculties should provide courses about media literacy to raise responsible citizens who can read scientific data in public discourse.

Regarding NOS, undergraduate students’ mean NOS score on the total score revealed moderate NOS conceptions. Akgün (2018) also measured NOS conceptions of undergraduate students from different faculties and found moderate NOS conceptions of participants on a total scale. Similar to Akgün’s (2018) study, undergraduate students’ lowest score was found in the methods and methodological rules dimension of NOS. This dimension aims to measure participants’ understanding about the explanatory power of empirical results and the existence of different scientific methods in developing scientific knowledge. Participants who have high scores on this dimension can easily understand that manipulative, non-manipulative, hypothesis testing, and non-hypothesis testing methods work in synergy to produce scientific knowledge (Kaya et al., 2017). In this dimension, it is also expected to understand that different scientific methods may yield different scientific knowledge (Kaya et al., 2017). As it is seen in the SSR scores, undergraduate students have difficulty in recognizing the need for ongoing inquiry in the resolution of issues. This may be related to their lack of understanding of the methods of inquiry.

Moreover, similar to Akgün’s (2018) results, participants had the highest scores on scientific practices and socio-institutional systems of science. Scientific practices include six main compounds: Real world, prediction, explanation, model, data, and activities reflecting epistemic, and cognitive and socio-institutional characteristics of science (Erduran and Dagher, 2014). Participants who have high scores on this dimension are expected to understand that these practices are used in scientific knowledge production correlatively. In Akgün’s (2018) study, students from both science and non-science majors had a sophisticated understanding of scientific practices dimension. The students in that study mentioned different scientific methods, such as observation, hypothesis construction, and observation. This indicates that they had an awareness of different scientific practices. In this study, all students were pursuing a science major. They have an awareness of different scientific practices at least related to their own majors. A qualitative investigation of their conception of scientific practices may yield differences in the types of practices; however, all of the students are aware of the existence of different scientific practices.

The social-institutional systems dimension of NOS is related to the understanding of some social, institutional and economic factors pertaining to scientific processes (Kaya et al., 2017). In Akgün’s (2018) study, undergraduate students were aware of social norms and their influence on scientific practices. However, Ryder et al. (1999) found that undergraduate science students involving in a project work underestimated the role of social processes in science. Their participants did not consider the role of social-institutional systems on the validation of knowledge claims and on the direction of lines of scientific inquiry. Throughout the project work, those students focused only on getting reliable data. Understanding this dimension is important for the resolution of SSI. Therefore, undergraduate students’ conceptions about this dimension should be investigated in detail with further research. Then, undergraduate programs should provide a realistic image of social practices of science to students.

In this study, differences in SSR competencies and NOS conceptions of students from different faculties were also investigated. There were differences among faculties in terms of SSR competencies and NOS conceptions. Health science students obtained the highest score on the SSR scale. This faculty includes the department of nutrition and dietetics, department of physiotherapy and rehabilitation, and department of nursing. In these departments, there are courses helping them to relate their profession with different domains and consider the problems of society. For example, in the department of nutrition and dietetics, a course named “Nutrition problems of society” is offered in the sixth semester. Similarly, in the same department, students can take elective courses such as “Nutrition in sustainable development,” and “Public relations.” In a similar vein, the department of physiotherapy and rehabilitation offers must courses including physiotherapy and ethical principles, sociology in physiotherapy, biochemistry in physiotherapy, and psychology in physiotherapy. By virtue of these kinds of courses, health science students may have developed a better insight in the way that they consider multiple perspectives of issues with ongoing social and scientific inquiry, approach scientific data skeptically, and comprehend the complex nature of societal problems.

Engineering Faculty students also obtained significantly higher scores than science students. The Engineering Faculty also offers a wide range of compulsory and elective courses, some of which are related to SSI such as energy technologies, environmental pollution types, and reasons. There are also many different courses related to different social disciplines such as marketing, public relations, labor law, economic analysis, sociology, occupational health and safety, and so on. On the other hand, students from the science department received the lowest score on the SSR scale. Participants from this department were pursuing their education in the department of mathematics, department of chemistry, and department of statistics. When these departments’ curriculum was examined, there were no compulsory courses related to societal problems. There were some elective courses requiring the consideration of different perspectives such as “Sociology” in the statistics department and “Chemistry of environment” in the chemistry department. However, these courses were offered in the way that they only provided the basic terms and definitions of the field, rather than developing students’ reasoning skills about
the issues related to the fields in concern. Therefore, the big difference between SSR scores of students from science and health science departments was not surprising.

The graduates of science departments could be expected to be leaders in scientific discovery and innovation. However, without functional scientific literacy, these individuals may not be involved in decision-making in controversial issues as responsible citizens. Therefore, undergraduate programs have a crucial role in developing scientific literacy. As Hall et al. (2017) suggested, courses like “Social Ethics” should be included in STEM-related undergraduate programs to emphasize the crucial role of values and norms held by different stakeholders in shaping scientific development. Moreover, college professors should have expertise in developing their students’ SSR competencies. Manske (2013) argued that college professors are often quite knowledgeable in their specific discipline, experienced in their fields, and an expert in teaching scientific and quantitative reasoning skills; however, they are incapable of helping their students in negotiating controversial issues in science. In this respect, the collaboration of departments offering courses from different perspectives to other departments may be a practical solution to these problems.

This study’s results were similar in NOS conceptions. In both SSR and NOS, the science students received the lowest score and obtained significantly lower scores than the engineering and health science students. Similarly, in Akgün’s (2018) study, undergraduate students from science-related departments had lower NOS scores than the non-science department students. Parker et al. (2008) also found that undergraduate science students did not have sophisticated NOS views. Parker et al. (2008) argued that undergraduate science students did not have much experience or conceptions about how science worked before attending laboratory activities. However, when in the laboratory, confirming scientific laws may mislead them so that they start to think that science only included proving or finding facts. Therefore, undergraduate science educators should explicitly teach students how science and scientific processes work.

There is an elective course in the chemistry department named “Nature of Science.” In this course, the NOS and scientific knowledge, scientific methods, scientific laws and theories, history and philosophy of science, and the relationships between science ethics and society are covered. However, to develop a sophisticated NOS view of all science faculty students, these kinds of courses should be offered as compulsory courses in all departments. Although science students are engaged in scientific practices in their courses, it is not sufficient to develop sophisticated NOS understanding. As Khishfe and Abd-El-Khalick (2002) indicated, assuming students develop NOS conceptions implicitly by being engaged in science-based inquiry activities is not an effective strategy for developing sophisticated NOS views. Studies showed that a combination of explicit and implicit NOS instruction is more effective in developing NOS conceptions (Akerson et al., 2000; Bell et al., 2011; McDonald, 2010; Vhurumuku, 2010). Developing students’ NOS conception is a cognitive instructional outcome. Therefore, instead of expecting students to understand the NOS only by involving in science processes, it should also be taught reflectively and explicitly in related must courses.

In this study, the relationship between NOS conceptions and SSR competencies was also investigated. Results indicated that NOS and SSR are not significantly correlated. As stated, previous studies have conflicting results on the relationship between SSR and NOS. Some researchers could not find significant relationships between different participants’ NOS conceptions and decision-making in controversial issues (Bell and Lederman, 2003; Walker and Zeidler, 2003). On the other hand, other researchers claimed the influence of NOS conceptions on decision-making on SSI (Kolstø, 2001; Lederman et al., 2014; Sadler, 2004; Sadler et al., 2004; Zeidler et al., 2002). Although a relationship is not generally found in quantitative studies, qualitative results have indicated a relationship between these two constructs. Therefore, the relationship between NOS and SSR should be simultaneously studied with both qualitative and quantitative data.

**CONCLUSION**

In this study, undergraduate students’ SSR competencies and NOS conceptions were investigated. First, the descriptive results concerning the dimensions of SSR and NOS were determined. Undergraduate students have moderate SSR competencies and NOS conceptions. The differences in SSR and NOS scores among students from different faculties were also investigated. Students from the science department had the lowest score in both constructs. On the other hand, health science students had higher scores on SSR. There were differences in the curriculums of these different departments. The health science department offers courses related to different disciplines including psychology, sociology, ethics, and so on. These courses may contribute to their students’ reasoning so that they are better at recognizing the complexity, multiple perspectives, and the need for ongoing inquiry in SSI. Moreover, although science students are more engaged in scientific inquiry in laboratories, they are less competent in comprehending the NOS. Offering courses in which NOS is explicitly taught are also recommended for all of the departments aiming to develop a sophisticated NOS view and scientific literacy.
