Abstract:
Given the importance of the beliefs and attitudes of the pre-service teachers, this research aims at studying the relation between mathematics teaching efficacy beliefs of pre-service teachers, their attitude towards mathematics and their mathematics academic achievement. Specifically, this work considers both factors together and studies their correlation with mathematics academic achievement. The Mathematics Teaching Efficacy Belief Instrument (MTEBI) is used to measure the teachers’ efficacy beliefs of pre-service teachers. Besides, the Attitude towards Mathematics Scale (AMS) is used to rate students’ attitude towards mathematics. Participants are 57 pre-service teachers of the third year of the primary education degree. Students of third years of the bachelor’s degree were invited to answer the MTEBI and AMS. Obtained results reaffirm that both teachers’ efficacy beliefs and attitude towards mathematics are key factors for pre-service teacher’s mathematics academic achievement. Moreover, the two factors correlate moderately with one another. Furthermore, results manifest that Personal Mathematics Teaching Efficacy (PMTE) is the most determining subscale for academic achievement. It is evidenced the importance of strengthening both the pre-service teachers’ efficacy beliefs and the attitude towards mathematics.

Keywords: pre-service teachers, mathematics teaching efficacy beliefs, attitude, mathematics academic achievement

INTRODUCTION
Existing research is concerned about the low mathematical elementary content knowledge of pre-service teachers (e.g., Mapolelo & Akinsola, 2015; Wu et al., 2018). This low mathematical content knowledge might provoke poor results in their mathematical academic achievement. Indeed, in addition to elementary content knowledge of pre-service teachers, there are different variables that were found to impact on academic achievement, such as self-concept (Byrne, 1990), values (Eccles & Wigfield, 2002), or more cognitive variables, such as learning strategies (Senko & Miles, 2008) or previous knowledge (Harackiewicz et al., 2002).

In the context of pre-service teachers, authors noticed that some students of the bachelor’s degree in primary education present low levels of mathematics teaching efficacy beliefs and a negative attitude towards mathematics (Boaler, 1997; Bursal, 2010). Literature research supports the importance of enhancing the pre-service teachers’ mathematics teaching efficacy beliefs (e.g., Bursal, 2010; Moody & DuCloux, 20015; Yang et al., 2020) and their attitude towards mathematics (e.g., Hourigan & Leavy, 2019; Michaluk et al., 2018), and how these factors influence to the mathematics academic achievement (e.g., Charalambous et al., 2009; Leavy et al., 2017; Ma & Kishor, 1997). As pointed out in Hannula (2012), it is still important and interesting to investigate the impact of variables concerning teachers’ mathematics related effect on other affective or cognitive variables such as academic achievement.
However, as far as we are concerned, there is no research taking both mathematics teaching efficacy beliefs and attitude towards mathematics together to study their correlation with mathematics academic achievement. This research aims at studying that correlation. Additionally, six subscales of the two considered factors (two subscales of efficacy beliefs and four subscales of attitude) are studied in order to determine their influence on academic achievement.

**Theoretical Framework**

In this section, the definitions of mathematics teaching efficacy beliefs and attitude towards mathematics are revised.

**Mathematics teaching efficacy beliefs**

The self-efficacy is one’s personal judgment about how well they can deal with a specific situation or task (social cognitive theory) (Bandura, 2001). A person’s self-efficacy could influence the effort they put forth in a given situation and how long they persist on a given task (Goddard et al., 2004). According to Bandura, people fear and tend to avoid threatening situations they believe exceed their coping skills, whereas they get involved in activities and behave assuredly when they judge themselves capable of handling situations that would otherwise be intimidating. Efficacy expectations determine how much effort people will expend and how long they will persist in facing obstacles and aversive experiences. The stronger the perceived self-efficacy, the more active the efforts.

Taking into account Bandura’s theory (Bandura, 1977, 1997), studies on teachers’ efficacy beliefs consider two separate dimensions (Hassan & Hassan, 2012). The first dimension, personal teaching efficacy, represents a teacher’s belief in their skills and abilities to be an effective teacher. The second dimension, teaching outcome expectancy, is a teacher’s belief that effective teaching can bring about student learning regardless of external factors such as home environment, family background, and parental influences (Swars et al., 2007).

Some researchers report that there exists relationship between efficacy belief and academic performance in the area of mathematics (e.g., Pajares, 1996). In addition, Perkmen and Pamuk (2011) determine that self-efficacy is a strong predictor of academic achievement in the pre-service teachers and that the outcome expectation is positively related to their academic achievement. Furthermore, Kaya and Cihan (2016) investigate the resources of mathematics self-efficacy and perception of science self-efficacy as predictors of academic achievement. According to their obtained results, resources of mathematics self-efficacy and perception of science self-efficacy are significantly correlated with academic achievement in high levels of influence.

**Attitude towards mathematics**

Attitude is a learned disposition or tendency on the part of an individual to respond positively or negatively to some object, situation, concept or another person (Aiken, 1970). Neale (1969) defined attitude to mathematics as an aggregated measure of a liking or disliking of mathematics, a tendency to engage or avoid mathematical activities, a belief that one is good or bad at mathematics, and a belief that mathematics is useful or useless. Attitude refers to a learned tendency of a person to respond positively or negatively towards an object, situation, a concept, or a person. It is also regarded as a belief held by individuals that reflects their opinions and feelings and can be sometimes manifested in behaviour. Attitudes, behaviour, and feelings are interrelated in such a way that people’s attitudes determine their behaviour towards objects, situations, and people (Mazana, 2020).

Several researchers suggest that the pre-service teachers should have a positive attitude towards mathematics, because it influences their mathematics academic achievement (e.g., Hemmings, 2010). Moreover, they can have a positive effect on the learning of their students in the future (Cakiroglu & Isiksal, 2009; Leavy et al., 2017). However, results of previous studies show that teachers of all levels of education often have negative attitudes towards mathematics (e.g., Boaler, 1997; Michaluk et al., 2018).
Besides, other researchers indicated that primary pre-service teachers, worldwide, possessed negative attitudes towards mathematics and fears about the teaching of mathematics (e.g., Charalambous et al., 2009; Cockcroft, 1982).

Related Work

As mentioned above, there are several researchers who highlight the importance of studying teachers’ efficacy beliefs in teaching mathematics and attitude towards mathematics as both factors significantly influence the students’ academic performance (e.g., Auzmendi, 1992; Chang, 2015; Hadley & Dorward, 2011; Nurlu, 2015).

Hadley and Dorward (2011) study the relationship between the mathematical anxiety of elementary school teachers, mathematics instructional practices, and students’ performance in mathematics. They show that low-level beliefs in self-efficacy to teach mathematics could cause mathematical anxiety, which, at the same time, can negatively influence student performance. In addition, they found a positive relationship between mathematics anxiety and anxiety about teaching mathematics. Moreover, they found that the increase in elementary school student performance in mathematics was related to lower levels of anxiety from teaching mathematics, but was not related to general anxiety about mathematics.

The results presented in Nortes and Nortes (2013) show that the attitude towards Mathematics in primary pre-teachers is very low. In addition, the authors indicate that the students perceive the teacher’s attitude. Therefore, if the attitude of the teacher is not positive, it negatively influences the attitude of their students.

Nurlu (2015) investigated primary school teachers’ characteristics by comparing their mathematics teaching self-efficacy beliefs. The author states that teachers with a greater belief in self-efficacy show a higher level of effort and persistence with students, being more open to new ideas and new methods. In addition, these teachers believe in students’ academic achievements and take responsibility for student success.

Chang (2015) examined the relationships between the efficacy of primary math teachers with the self-efficacy and mathematical performance of their students. Their results show that mathematics teachers’ beliefs of efficacy have a significant influence on the self-efficacy and performance of their students in mathematics.

Fachrudin et al. (2019) examined Pre-Service Mathematics Teachers’ (PSMTs) general knowledge of PISA (Programme for International Student Assessment) and their attitudes and beliefs towards using PISA-based problem in mathematics. The authors revealed the poor score results of PSMTs knowledge of PISA. Additionally, they stated that the teacher education program needs to improve the PSMTs PISA skills and knowledge.

More recently, Yang et al. (2020) studied the relationship between teachers’ knowledge, beliefs and instructional practices based on a sample of 495 pre-service mathematics teachers. Results indicated that Chinese pre-service mathematics teachers tend to hold mixed beliefs about the nature of mathematics, and a constructivist view about mathematics teaching and learning, and that they are inclined to report that their teaching is inquiry-oriented.

Objectives and Research Questions

Taking into account the above presented works, this research aims at studying, on the one hand, the relationship between pre-service teachers’ mathematics teaching efficacy beliefs and their attitude towards mathematics with their mathematics academic achievement. Both factors are considered important in the literature, but there is not any work studying both factors together, as far as we are concerned. Additionally, multiple linear regression is used in this research to determine the influence
of each studied factor to academic achievement. On the other hand, another goal of this work is to study if there are subscales of the considered factors with which there is a greater correlation with academic achievement. Therefore, the correlation among six subscales of the two factors (two in the case of teaching efficacy beliefs and five in the case of attitude towards mathematics) and mathematics academic achievement is also studied. Specifically, the current study was designed to answer the following questions:

a) How is the correlation between pre-service teachers’ mathematics teaching efficacy beliefs, their attitude towards mathematics and their mathematics academic achievement?

b) How is the correlation between the two subscales of mathematics teaching efficacy beliefs, the five subscales of the attitude towards mathematics and the mathematics academic achievement?

METHODOLOGY

This section presents the methodology adopted in this research.

Participants and Teaching and Learning Mathematics Course

The sample used in this investigation is a purposive sample (Patton, 2002). The participants in this study are students of the bachelor’s degree in Primary Education at University Rovira and Virgili, which consists of a four-year program, composed by eight semesters. The first year of the program contains only introductory pedagogical courses. The Bachelor includes three mandatory courses of Teaching and Learning Mathematics (TLM).

Table 1 shows the distribution of the three TLM courses along the bachelor’s degree. It also shows the semester when the mathematical content exam and the MTEBI and AMS were administrated.

The TLM1 course (2nd year) presents the mathematical content pre-service teachers need to know to teach in Primary school. The students have to review mathematical content and processes, and to solve problems. In the TLM2 course (3rd year), the pre-service teachers learn how to use manipulatives and interactive applications to teach Numeracy at Primary school. Finally, in the TLM3 course (4th year), the teacher presents them materials to teach Geometry at Primary school. The sessions of TLM3 consist of Geometry workshops, in which the students work in teams.

During several years, authors noticed low levels of mathematics teaching efficacy beliefs and negative attitudes toward mathematics among pre-service teachers enrolled in the bachelor’s degree in primary education. However, there is not any study quantifying those feelings at the current University. Concretely, the most negative feelings and the worst mathematics academic achievement occur during the TLM 1 course, which mainly includes mathematical content. The participants of this study are students of the third year of the Bachelor. They have only coursed the TLM 1 course, which is given during the second year of the Bachelor, as shown in Table 1.

As detailed in short, the mathematics academic achievement was assessed by taken the grade they were given in the TLM 1 course during the 2018-19 academic year. A total of 97 students were enrolled to TLM 1 course. Moreover, students of the third year that attended at the TLM 2 course class at the beginning of the 2019-20 academic year were invited to answer the MTBI and the AMS. Therefore, participation was voluntary and anonymous. Students indicated the initials of their name in order to establish correspondences with the marks obtained in the TLM 1 course (the marks were provided by
the corresponding teacher and by using the same code). Once the correspondences were made, all codes were deleted.

Specifically, the participants of this study correspond to 56 students out of the 70 enrolled in the third year of the degree of primary education (81% of the total population), students who attended classes. Notice that only the students that had already attended to the TLM 2 course could be selected for the study. The test was not applied in semesters S3, S6 and S7 because they did not have the TLM course.

Participation in this test was optional. Considering these aspects, it was not necessary to have the consent of the research participants.

Instrument

As mentioned above, three different instruments were used in this research: 1) the Mathematics Teaching Efficacy Belief Instrument (MTEBI) for pre-service teachers (Enochs et al., 2000), 2) the Attitude towards Mathematics Scale (AMS) for pre-service teachers (Auzmendi,1992), and 3) an exam of mathematical content.

The Mathematics Teaching Efficacy Belief Instrument (MTEBI)

The Mathematics Teaching Efficacy Belief Instrument (MTEBI) for pre-service teachers results from the modification of the Science Teaching Efficacy Belief Instrument STEBI-B (Enochs & Riggs, 1990) and aims at reflecting future mathematics teaching beliefs. Indeed, the MTEBI for pre-service teachers has been widely used to measure mathematics teaching self-efficacy and teaching outcome expectancy (e.g., Giles et al., 2016; Moody & DuCloux, 2015; Newton et al., 2012; Segarra & Julià, 2020; Swars et al., 2007). The original MTEBI consisted of 21 items in a five-point Likert scale measuring one (strongly disagree) to five (strongly agree). As in Liu et al. (2007), and Segarra and Julià (2020), the third Likert scale item, uncertain, was deleted in the current work to encourage all participants to indicate a level of certainty.

The questions that conform the MTEBI in the case of pre-service teachers are detailed in Table 2. The MTEBI is comprised of two subscales, the personal mathematics teaching efficacy (PMTE) subscale, and the mathematical content.

which is composed of 13 items (2, 3, 5, 6, 8, 11, 15, 16, 17, 18, 19, 20, and 21) and Mathematics Teaching Outcome Expectancy (MTOE) subscale, which is composed of 8 items (1, 4, 7, 9, 10, 12, 13, and 14). Eight of the items of PMTE are reverse scored (3, 6, 8, 15, 17, 18, 19 and 21). The responses corresponding to these items must be inverted before being added into the total PMTE score (4=1, 3=2, 2=3, and 1=4).

The Attitude towards Mathematics Scale (AMS)

There exist different instruments measuring the attitude towards mathematics. Some of them are studied in Aiken (1979), Fennema and Sherman (1979), Auzmendi (1992), Tapia and Marsh (2004), Adelson and McCoach (2011). Auzmendi (1992) drew up one of the most cited attitude scale towards mathematics, to the usefulness that he perceives that this subject may have for professional life. The current research uses the attitude towards the mathematics scale (AMS) proposed in Auzmendi (1992), since it is an instrument designed in Spanish and specifically developed for pre-service teachers.

The AMS has five subscales (pleasure, anxiety, usefulness, motivation and confidence). According to Auzmendi, the pleasure towards mathematics refers to the enjoyment caused by mathematical work. The anxiety towards mathematics refers to the feeling of anxiety, fear that the person manifests in the matter of mathematics. The usefulness subscale refers to the value that a student attaches to mathematics, to the usefulness that he perceives that this subject may have for professional life. The motivation subscale represents how the student feels towards the study and the use of mathematics. Finally, the confidence subscale is the feeling caused by the ability towards mathematics.

The AMS consists of 25 items on a five-point Likert scale that measures from one (strongly disagree) to five (strongly agree) and is used in several investigations (e.g., Fernández, 2010; Morales, 2000; Nortes & Nortes, 2014). The items of the AMS are detailed in Table 3. As in the MTEBI, the third element of the Likert scale, which was in the original version of the AMS, was removed. As mentioned above, the AMS

</table>
establishes five subscales: pleasure (items 4, 9, 14 and 24), anxiety (items 2, 3, 7, 8, 12, 13, 17, 18 and 22), motivation (items 5, 10, and 25), usefulness (items 1, 6, 15, 16, 19 and 21) and confidence (items 11, 20 and 23). Ten of the AMS items have a reverse score (items 2, 5, 7, 10, 12, 15, 16, 17, 22 and 25). The answers corresponding to these items must be reversed before being added to the total AMS score (4 = 1, 3 = 2, 2 = 3 and 1 = 4).

Mathematical Content Exam

Academic achievement in mathematics was assessed during TLM 1 by averaging the scores obtained in different assessment activities. Two of these activities are exams designed to assess the mathematical content knowledge of pre-trained teachers. In addition, they had to be able to explain the problems correctly. Specifically, exams consist of arithmetic and geometry problems. The exams is scored on a scale from 0 up to 10.

Data Analysis

In order to determine the reliability of the obtained results, Cronbach’s alpha test was applied (Cronbach, 1951). Table 4 shows Cronbach’s alpha coefficients for the MTEBI and its two subscales (PMTE and MOTE) and for the AMS and its five subscales (pleasure, anxiety, motivation, usefulness and confidence). Rules proposed in George and Mallery (2003) are considered to interpret the obtained alpha values. In the case of motivation and confidence subscales, the values of Cronbach’s alpha are poor and unacceptable, respectively. Due to that, the confidence subscale was eliminated before the analysis. It is important to note that Cronbach’s alpha for AMS is excellent and for MTEBI it is acceptable.

In order to identify the correlation method and the regression analysis that can be used in this investigation, we study the contrast of the normal population distribution (Shapiro & Wilk, 1965). Results of the tests indicate that data normality can be accepted in each of the three groups MTEBI, AMS and academic achievement (p-value > 0.05) (Shapiro & Wilk, 1965). Considering these results, the Pearson’s correlation coefficient and the multiple linear regression are used in this study.

RESULTS

This section is organized into two subsections, each of which corresponds to each of the research questions. The first subsection examines the correlation between the pre-service teachers’ mathematics teaching efficacy beliefs, their attitude towards mathematics and their mathematics academic achievement. The second subsection studies the correlation between subscales of MTEBI (self-efficacy of the teaching of mathematics and outcome expectancy of the teaching of mathematics), subscales of AMS (pleasure, anxiety, motivation, usefulness and confidence) and mathematics academic achievement.

Correlation Between Mathematics Teaching Efficacy Beliefs, Attitude Towards Mathematics and Mathematics Academic Achievement

First, the arithmetic mean (\( \bar{x} \)) and the standard deviation (\( \sigma \)) obtained in the MTEBI and AMS are computed. Besides, the marks obtained in the TLM 1 course are collected as mathematics academic achievement. Table 4 shows the arithmetic mean and standard deviation of the MTEBI, the AMS and the academic achievement obtained by the pre-service teachers. Recall that the MTEBI and the AMS are given values up to 4, while the academic achievement is measured up to 10.

Table 5 shows that the mean of the MTEBI values is higher than the one obtained in the AMS. In addition, it is observed that the deviation of the AMS is wider than the MTEBI.

Moreover, we study the relationship between the pre-service teachers’ efficacy beliefs, attitude towards mathematics and academic achievement through the Pearson’s correlation coefficient. Table 6 summarizes the obtained results.

Results shown in Table 6 indicate that there is a significant moderate correlation between teachers’ efficacy beliefs and academic achievement, and also between attitude towards mathematics and academic achievement (0.69 > \( r \) > 0.40). In addition, there is a significant moderate correlation between the teachers’ efficacy beliefs and between the attitude towards mathematics (0.69 > \( r \) > 0.40).

Finally, a multiple linear regression analysis between the teachers’ efficacy beliefs and attitude towards mathematics (independent variable predictors) and mathematics academic achievement (dependent variable) is carried out. Results of the multiple linear regression analysis are shown in Table 7.

The variables teachers’ efficacy beliefs and attitude towards mathematics show a significant relationship with academic achievement. The coefficient of determination indicates that 54% of the variation in the output variable (predicted variable) is explained by the input variables (predictor variables). In other words, the two predictor variables explain 54% of the change in academic achievement score.

Furthermore, the obtained Standardized Beta Coefficient indicates that the most powerful variable is teachers’ efficacy beliefs (\( \beta = 0.54, p < 0.001 \)). In the case of the attitude towards mathematics, the Standardized Beta Coefficient is \( \beta = 0.29, p = 0.001 \). These values evidence that the two factors predict significantly academic achievement.

Correlation among Subscales of Mtebi, Subscales of Ams and Mathematics Academic Achievement

This section studies together the two subscales that conform the MTEBI (self-efficacy of the teaching of mathematics and outcome expectancy of the teaching of mathematics) and the four considered from the
AMS (pleasure, anxiety, motivation and usefulness). Recall that the subscale confidence was removed due to the unaccepted reliability provided by Cronbach alpha.

Table 8 shows the arithmetic mean (\( \bar{x} \)), the standard deviation (\( \sigma \)), and the Pearson’s correlation coefficient value (\( r \)) between the two subscales of MTEBI, the four subscales of the AMS, and academic achievement. It should be noted that the anxiety subscale has been reversed scored. That is, the higher the score is, the less the anxiety.

In addition, in the case of MTEBI, the PMTE subscale has the highest mean. In the AMS, the motivation subscale has the highest mean. The lowest score, on the contrary, is obtained in the pleasure subscale.

Results summarized in Table 8 shows that there is a significant high correlation between the teaching self-efficacy (PMTE) and academic achievement. In the case of the outcome expectation (MTOE), its correlation with the academic achievement is very low and it is not statistically significant. In the case of the AMS subscales, results show that the correlation between both anxiety and usefulness and academic achievement is moderate (\( 0.70 > r > 0.39 \)). Specifically, the highest correlation with academic achievement is found in the case of the anxiety subscale (\( r = 0.57, p < 0.05 \)). The lowest correlation, on the contrary, is obtained between the motivation subscale and academic achievement (\( r = 0.27 \)) and in this subscale, the obtained result is not significant (\( p > 0.05 \)).

Finally, a multiple linear regression analysis between the six subscales and mathematics academic achievement is carried out taking the independent variables predictors (self-efficacy of the teaching of mathematics, outcome expectancy of the teaching of mathematics, pleasure, anxiety, motivation and usefulness) and the dependent variable (mathematics academic achievement). Table 9 summarizes obtained results.

Results shown in Table 9 indicate that there is a significant dependent relationship between the subscales and academic achievement. The coefficient of determination (\( R^2 = 0.59 \)) indicates that 59% of the variation in the output variable (predicted variable) is explained by the input variables (predictor variables). Therefore, the six predicted variables explain 59% of the change in academic score. According to the obtained Standardized Beta Coefficient values, the order of influence of the predictor variables on academic achievement is the following: self-efficacy of the teaching of mathematics (\( \beta = 0.58 \)), outcome expectation (\( \beta = 0.14 \)), pleasure (\( \beta = 0.13 \)), anxiety (\( \beta = 0.08 \)), usefulness (\( \beta = 0.06 \)) and motivation (\( \beta = 0.05 \)).

Considering the obtained correlation (\( p > 0.05 \)) and Standardized Beta Coefficient (\( \beta = 0.13, p > 0.05 \)), the MTOE subscale is removed from the initial model. Five independent variables predictors (self-efficacy of the teaching of mathematics, pleasure, anxiety, motivation and usefulness) and dependent variable (mathematics academic achievement) define the new model. The values of the new model are equal to model 1, but the Standardized Beta Coefficient values are slightly modified. Again, the most powerful variable is self-efficacy of the teaching of mathematics (\( \beta = 0.59 \)), followed by pleasure (\( \beta = 0.19 \)).
DISCUSSION

This research aimed at studying pre-service teachers’ mathematics teaching efficacy beliefs, their attitude towards mathematics and their mathematics academic achievement. Besides, it also aimed at studying the correlation between subscales of MTEBI (self-efficacy of the teaching of mathematics and outcome expectancy of the teaching of mathematics), subscales of AMS (pleasure, anxiety, motivation, usefulness and confidence) and mathematics academic achievement.

Regarding the first research question, results reaffirm that there is a significant moderate correlation between the mathematics teaching efficacy beliefs and academic achievement ($r = 0.66$). That is, teachers with greater teachers’ efficacy beliefs showed a better academic achievement. This result is in accord with the work presented in Schunk and Mullen (2012), where the self-efficacy is related to mathematics academic achievement. Results also show a moderate correlation between the attitude towards mathematics and academic achievement ($r = 0.60$). This result is consistent with previous research that supports the influence of the attitude towards mathematics of pre-service teachers in their academic achievements in mathematics (Hemmings, 2010). Additionally, results manifest a significant moderate correlation between both factors ($r = 0.47$). This result allows to conclude that both factors are not redundant (its correlation is not high), so they provide different and useful information.

From the multiple linear regression analysis it can be concluded that mathematics teaching efficacy beliefs is the most powerful factor to predict academic achievement ($\beta = 0.54$).

Therefore, this research emphasizes that both positive mathematics teaching efficacy beliefs and a positive attitude towards mathematics of pre-service teachers have a positive effect on their academic achievement.

Concerning the second research question, it is shown that the subscale PMTE presents a significant high correlation with academic achievement ($r = 0.72$). The MTOE subscale, on the contrary, presents a low correlation and it is not significant ($r = 0.16, p = 0.11$). These results are consistent with the theoretical predictions based on Bandura’s works (Bandura, 1986; 1997), where it is affirmed that self-efficacy beliefs predict academic outcomes. Obtained results also coincide with other previous researches (Kaya, & Cihan, 2016; Pajares, 1992; Pajares & Graham 1999; Pajares & Miller, 1994; Zimmerman, 2000), where authors indicated that there is a relationship between self-efficacy and academic achievement.

The second highest correlation coefficient is obtained between the anxiety subscale and academic achievement ($r = 0.57$). Some researchers also determined that there is a relationship between anxiety and academic achievement (Devine et al., 2012; Pajares & Miller, 1994; Swars et al., 2006). That is, more anxiety implies less academic achievement.

Results obtained applying a multiple linear regression show that the most powerful variable to predict academic achievement is PMTE subscale ($\beta = 0.59$). The second powerful variable to predict academic achievement is pleasure ($\beta = 0.18$). In the current context, pleasure is the subscale with the lowest given mean. Therefore, a clear implication of this research would be to try to improve the pleasure pre-service teachers feel towards mathematics. According to the obtained results in this research, that improvement will benefit the mathematical academic achievements.

Indeed, considering the impact of the mathematics teaching efficacy beliefs and the attitude towards mathematics with respect to academic achievement, teachers training programs should help pre-service teachers to develop more positive beliefs and attitudes towards mathematics. A clear implication of this research would be to include an evaluation of the mathematics teaching efficacy beliefs and the attitude toward mathematics of the pre-service teachers. Additionally, its evolution throughout the bachelor’s degree should also be studied.
Although this research is focused on a reduced population and a specific context, we believe that the significant relationships found in this investigation allow to extend the same conclusions to a larger population and other contexts.

CONCLUSIONS

The purpose of this research was to study the relationship between mathematics teachers’ efficacy beliefs and attitude towards mathematics of primary pre-service teachers and their academic achievement.

Two instruments were selected to study each of the factors: the MTEBI aims at measuring the teachers’ efficacy beliefs, while the AMS aims at assessing the attitude towards mathematics. It should be highlighted that each instrument is composed by subscales (two and four, respectively). This research studies in detail each of the six subscales, in order to determine the correlation between each of them and academic achievement. Unlike the referenced literature, two factors (beliefs and attitude) and their six subscales were studied together in this research.

Results reaffirm that the mathematics teaching efficacy beliefs and the attitude towards mathematics have a significant moderate correlation with academic achievement. Furthermore, the two factors are moderately correlated one to each other. This result confirm that they are not redundant. On the other hand, the multiple linear regression evidence that mathematics teaching efficacy beliefs is more powerful than the attitude towards mathematics to predict mathematics academic achievement.

Additionally, results show that the teaching self-efficacy (PMTE) subscale has the highest correlation with academic achievement of pre-service teachers, followed by the anxiety subscale. The multiple linear regression analysis shows that the PMTE subscale is the most powerful variable to predict academic achievement, followed by pleasure.

This work can be very useful for institutions that design pre-teachers training programs. They can realize that it is important to promote the mathematics teaching efficacy beliefs and the attitude towards the mathematics of their students, since both factors contribute significantly to academic achievement. Furthermore, they can obtain valuable information by analyzing in detail the results obtained in each studied subscales. That analysis would allow to detect possible weakness of students. These weaknesses could be tackled by adapting the curriculum of the degree correspondingly.

A future line of research would be to collect data on beliefs and attitudes towards mathematics considering all the students of the primary education degree and to study their evolution throughout the different academic courses. The idea would be to analyze the beliefs and attitudes towards mathematics at the end of the mathematics teaching and learning courses conforming the degree, to study the impact that the methodological strategies applied in each of them have on these two factors.
